are used. In Berlin and various parts of Germany previous stunning is compulsory. In Holland all animals brought to slaughter must be stupefied by ball or needle bullets. In Norway all cattle are killed by shot before blood-drawing. In France generally the pole-axe and pith are used for large animals, and small animals are stunned and bled. In Chicago, where meat production is on a vast scale, cattle and sheep are stunned with a long-handled hammer, or the spinal cord is severed by means of hammer and chisel. In London the practice has been, in the case of bullocks, to strike on the forehead with the pole-axe; in the case of sheep, to divide the large vessels of the neck and immediately sever the spinal cord between head and neck; and in the case of pigs usually, though not always, to stun with a wooden mallet. The Local Government Board in 1915 advised the adoption of the mechanical appliance popularly known as the "humane killer." The Public Health Committee of the Council has heard evidence from the Royal Society for the Prevention of Cruelty to Animals in favour of mechanically operated instruments which produce immediate unconsciousness, a bullet or bolt smashing through the skull and causing concussion of the brain. The meat traders have opposed the new by-law on account of the risk involved in firing a bullet in a slaughterhouse and of the possibility that the quality of the meat may be adversely affected owing to the ineffective draining of the blood from the carcasses of animals so shot. There is conflict of evidence as to the results of a demonstration which took place in Belfast when certain animals were submitted to slaughter by the new and certain others by the old method. The traders state that it was proved that the meat of the animals on which the pole-axe had been used kept better; on the other hand, the local society for the prevention of cruelty to animals had traced the carcasses of the bullocks put to death by mechanical methods and found that the meat was sold in the usual way at market prices without loss or inconvenience to the butchers or complaints from their customers. Dr. Gerald Leighton, medical officer (foods), Scottish Board of Health, is quoted as having found by microscopical examination of the meat that the view that the bleeding was imperfect when mechanical instruments were used could not be upheld. Sixty-four local authorities have adopted the by-law requiring a mechanical method of stunning. In many cases their experience has been too brief to admit of any proper judgement, but twenty-three reported favourably on the "humane killer," subject to slight qualifications in six cases. The proposed new by-law, which was agreed to by the London County Council without a division, applies to 153 slaughterhouses, but not to the large slaughterhouses associated with the Islington Cattle Market, which are under the control of the City Corporation. The number of slaughterhouses in London has greatly declined during the last thirty years, owing chiefly to the large percentage of imported meat now consumed. In the London Central Meat Market the average weekly pitch of meat is from 8,000 to 10,000 tons, and 85 per cent. of the beef and 93 per cent. of the mutton is imported.

#### ROYAL SANITARY INSTITUTE CONGRESS.

The annual congress of the Royal Sanitary Institute will be held at Hull from July 30th to August 4th, with the Right Hon. T. R. Ferens, High Steward of Hull, as president. The work of the congress will be carried on in sectional meetings and conferences. The sections are four in number—namely, sanitary science (of which Sir William H. Hamer is president), engineering and architecture, maternity and child welfare, including school hygiene (of which Dr. J. R. Kaye is president), and personal and domestic hygiene. There will be conferences of representatives of sanitary authorities, representatives of port sanitary authorities, medical officers of health (chairman, Dr. T. Eustace Hill), engineers and surveyors, veterinary inspectors (chairman, Dr. O. Charnock Bradley), sanitary inspectors, and health visitors (chairman, Professor H. R. Kenwood). Sir Alexander Houston will deliver a lecture to the congress on "A pure water supply," and Mr. B. Seeborn Rowntree will give the popular lecture on "Industry and national welfare." A health exhibition will be held in connexion with the meeting. A public luncheon will take place in the Guildhall on the first day, and the congress dinner on the last day of the congress; arrangements are being made for visits to places of interest in connexion with the sanitary administration of the district. The honorary local secretaries of the congress are Mr. H. A. Learoyd, town clerk, and Dr. J.

Wright Mason, medical officer of health, Hull. Papers intended to be read at the congress should be sent before June 25th to the secretary, Royal Sanitary Institute, 50 Buckingham Palace Road, London, S.W.1.

## Correspondence.

### L'ENTENTE HYGIÉNIQUE.

SIR,—The Second International Interchange of Public Health Officers held under the auspices of the Health Section of the League of Nations, and organized by the Society of Medical Officers of Health, having completed its course in Great Britain on April 10th, the visiting health officers are proceeding to Austria and Switzerland for further studies.

At the moment of departure the foreign delegates to this Interchange are happy to avail themselves of the columns of the BRITISH MEDICAL JOURNAL in which to voice some expression of their appreciation of the magnificent opportunities for study which have been placed at their disposal, and of the courtesy with which all arrangements have been carried out.

This is not the time to present a critical analysis of the current health practice of England in detail. That will come when the delegates, after careful study of the extensive reports and documents with which they have been furnished, and a resurvey of their own notes in perspective, are in a position to hand in their reports to their respective Governments. But at the present time the outlines of the composition are before them, and a sufficiently impressive picture it makes.

What the visitors intend to refer to at present is not the public health system of Great Britain, but rather the course of study which they have enjoyed the privilege of taking here. On this subject they are of one opinion, that it was wisely planned, and has been carried out in the most efficient and graceful manner, so as to set a standard for future interchanges of this nature which it will be difficult to maintain and perhaps impossible to surpass.

The delegates feel that it will be impossible for them to thank by name the hundreds of officials who have contributed with unflinching courtesy and patience to their instruction and comfort, or even to mention the various Government departments which have planned and contributed to the programme, or the voluntary organizations which have joined with the rest in their entertainment. Let us say to all of these earnest, public-spirited men and women, who spend their lives in the service of humanity, that they have given us freely of their best, that they have instructed our minds and have touched our hearts, and that we are grateful. The task remains to us to turn to the best account the effort which has been expended here in behalf of human welfare.—We are, etc.,

### PSYCHO-ANALYSIS.

SIR,—From Dr. Ian D. Suttie's letter in the BRITISH MEDICAL JOURNAL of December 23rd, 1922, I gather that even in Great Britain—the nerve centre of empire—prophets are still without honour in their own country, otherwise he might have found that the "wild conjectures such as Dr. Berry mistakes

for facts" are almost entirely based on the acknowledged works of, to mention but a few, Sherrington, Flack and Hill, Dr. J. S. Bolton, Dr. G. A. Watson, and in America, Ranson and Herrick. In the second edition of the last mentioned author's *Introduction to Neurology* will be found a complete list of the various receptors of the human body, without which, I venture to remind Dr. Tippet, there cannot even be a "hypothetical psyche," but merely an idiosyncrasy from deprivation of the senses. In the 1919 edition of Flack and Hill's *Textbook of Physiology*, page 732, may be read "extero-, proprio-, and entero-ceptive impulses stream into the central nervous system from the time of its embryonic development until death, ceaselessly modify the pattern of its structure, lay down the pathways of reflex actions, and establish habits. A very large proportion of these impulses, and particularly the proprio- and entero-ceptive, never enter into consciousness, and yet occasion actions which are perfectly adapted to the end in view." On page 720 of the same work—and, indeed, in many others—we find that the functions of the great brain are, amongst other things, "the reception of impulses and the storing of the effects of such impulses." The italics are mine.

In Dr. J. S. Bolton's book, *The Brain in Health and Disease*—a masterpiece of scientific observation and logical deduction—as also in his article in Leonard Hill's *Further Advances in Physiology*, will be found an account of the control exercised by the supragranular layer of cortical neurons, and of the effects of removal of such control from either maldevelopment or disease. Whilst it would be easy to multiply authority upon authority in support of my original statement, space will not permit, so, though I cannot claim the honour, as some of your correspondents seem to imagine, of being a disciple of Sir Clifford Allbutt, I can at least pay him the compliment of quoting his words: "Is it unfair to say that the interpretations given by psychoanalysts to the dreams of our modern Jacobs and Daniels are incredible nonsense?"

Dr. Charles F. Harford leaves a weightier missile. He quotes the President of the British Association as having said that "the physiologist could not explain mind." It has not been my privilege to read this address, but I venture to believe that its distinguished author was rather venturing to hint the unspoken thought of most of us who study the human brain, which is our humble admiration of a mightier power than ourselves. Whether this be so or not—I hope it was—I feel confident that Sir Charles Sherrington was neither unadvised nor ignorant of the labours, in this very field, of the morphologist who can indisputably prove from comparative anatomy, embryology, physiology, and pathology, that neurons in combinations of arcs are the physical instruments of mind.

It is not uncommon to find the human mind spoken of—especially by those with no knowledge of brain structure, and these are unhappily many—as though it were something which had no physical basis whatsoever, but was the result of a Psyche or soul. This conception is both erroneous and productive of error. Comparative anatomy clearly proves that the gradual rise in the scale of animal intelligence is strictly correlated with a progressive increase in the numbers of cephalic neurons, particularly those of an internuncial character.

Every branch of study shows that the structure of the nervous system is everywhere built up of a series of long conducting neurons, connected together by a series of shorter neurons. The former comprise the receptor and effector neurons; the latter, the internuncial. Medical attention has so far been chiefly devoted to the long conducting neurons, because lesions occurring therein have been fairly obvious and are of everyday frequency. In the study of the phenomena of mind and its aberrations it is, however, the shorter internuncial neurons which become of supreme importance, and to these an altogether insufficient amount of attention has been devoted.

In the human brain the association or "silent" areas contain many million neurons of this type, and physiological and neurological opinion of the functions of these areas may be gauged from the following:

Starling says that the greater part of the brain surface is taken up "with the nervous material of the type which is connected with the functions of association involved in the higher processes of reflection, intelligence, and volition."

Flechsig advocates the view that the association areas are the portions of the cortex in which the higher and more complex mental activities are mediated, the true organs of thought.

Howell says, "In the association areas our memory records of

past experiences and their connexions are laid down in some, as yet unknown, material change in the network of nerve cells and fibres."

The extraordinary thing is that these association areas do not differ materially in structure from any other part of the nervous system. They simply contain millions of short neurons which, from their morphological construction, appear to be of the internuncial variety. They resemble the neurophile of the common earthworm, with this striking difference, that whereas the neurophile of the earthworm contains but few internuncial neurons the association areas of the human brain contain many millions. From the brain of the normal man remove about one-half of his 9,280 million neurons (Herrick) and there will result either the microcephalic idiot or the anthropoid ape—the former with little speech, the latter with none. Clearly then neurons in sufficient numbers are the instruments of all mental phenomena, and our knowledge of their connexions, though leaving much to be desired, is really very much more precise than Dr. Harford seems to imagine.

Now the importance of all this is that we are beginning to know that there are quite a large number of human individuals who, from some cause or another, do not possess their fair share of cortical neurons. Dr. Bolton's work—as well as that of others—affords ocular and indisputable proof of this, and yet we go on expecting these unfortunate people to react to their environment in a normal manner, and delude ourselves with the idea that psychoanalysis can replace nature. Just as bricks cannot be made without straw, neither can the brain perform its correct mental reactions if it be deficient in numbers of properly functioning neurons. From the neuronic standpoint, all human individuals may be divided into three great groups: cerebral aments, who swell the ranks of our prisons, gaols, reformatories, and asylums—though I must not be supposed to imply that all such inmates are aments; normal neuronic individuals, who form the bulk of mankind; and the few to whom we owe almost all progress, the multi-neuronic men of genius. To one and all alike dementia, given a sufficient longevity, is the common ultimate fate—that is, an atrophy of mental power, through a gradual death of the cortical neurons. As a matter of fact there are far more cerebral aments outside our institutions than in them, and many of these find their way into our consulting rooms, where they largely remain unrecognized.

It was in the hopes that some slight indication of the trend of modern neurology might be of service to the practising profession that I ventured to enter this discussion. If psychoanalysis is to be of any real benefit to suffering humanity its practice must be removed from the hands of the ignorant, and placed upon a sure basis of structure, for, as Starling says, "in the central nervous system, more than in any other part of the body, function is directly dependent on structure."

Even on the outposts of empire some of us, within our limitations, do endeavour to keep abreast of modern scientific progress, and, strangely enough, occasionally contribute thereto. We are not, therefore, cursed with credulity, and require something more than the entrancingly and easily uttered "wild conjectures" of certain schools of psychoanalysts as a substitute for the much more laboriously acquired "facts" of neurology.—I am, etc.,

University of Melbourne, Feb. 19th. RICHARD J. A. BERRY, M.D.

#### LUNACY LAW AND THE TREATMENT OF THE INSANE.

Sir,—Dr. Edwin Goodall's letter in your issue of March 24th contains an implication which, if unchallenged, must certainly further obscure the grounds of this controversy. Dr. S. E. White, in the same issue, writes a characteristic letter which, while rightly appealing for the establishment of cheerful hostels for early cases, runs on purely hospital lines, repeats the usual misleading inferences in regard to the wider question involved.

Both your correspondents seem to underline that "Abandon hope, all ye who enter here" which unkindly and irresponsible thought has imagined for the portal of an asylum, so utterly unjust and cruel.

Now, Sir, Dr. Goodall, whose opinion must command respect and who is himself a medical superintendent of a mental hospital which he is no doubt determined shall be second to no other hospital, nevertheless appears to have become so moonstruck by his "assemblage of splendid persons" that he is led to express views the reverse of

helpful to the cause which he, equally with all of us, must have at heart.

The tendency of both your correspondents is to divide up an indivisible question. Mental disease will not be altered in kind by being treated in a hostel or clinic, and the improvement of mental hospitals will not be advanced by implying that they must not, or cannot, be expected to supply "the most effective treatment." It is the same problem everywhere, and everywhere there must be the same ideal—namely, the most efficient treatment.

In this vexed controversy it may serve some purpose to summarize those points about which practically all opinion is in agreement; they are:

1. Amendment of certain provisions of the Lunacy Act, 1890.
2. The establishment of central clinics for incipient mental disease in close association with the general hospitals and medical schools.
3. The general principle that early mental illness must not be placed in close association with protracted insanity.
4. The hospitalization of asylums, and the provision of improved training for the nursing staff.
5. The freedom to treat early border-line cases without certification, wherever the patients and their doctors like to arrange for this, whether in hostel, sanatorium, or elsewhere. Most of us would, I think, include amongst the latter the mental hospital, although the National League for Lunacy Reform in its wisdom would probably object, and Dr. Goodall appears to agree.

No doubt we shall soon be allowed to receive voluntary boarders in county hospitals, and while no one would suggest that there is any necessity to force ("lure" is a word often used by critics) early cases to seek treatment in mental hospitals, I have personally little doubt that many will of their own accord apply, and past experience has frequently borne testimony to the fact of the desire of many persons suffering from mental trouble to be readmitted and placed under treatment in mental hospitals.

Underlying these points of agreement are the following fundamental requirements:

1. Medical research and training in psychiatry.
2. The better training of nurses and the attracting of the right class of nurse for mental patients.
3. Public enlightenment as to the meaning and cause of mental disorder.

These are objectives which can alone be attained by concentration upon the main question—What is the most effective means for obtaining the most efficient treatment for all persons mentally ill?

Does anybody suppose that centrally placed clinics and the staffs of general hospitals are really within measurable time going to deal with more than a fraction of the great mass of mentally afflicted that annually require help?

I submit that there is the most urgent need for asylums to continue their evolution into hospitals, which they are courageously attempting at the present time, often in the face of much discouragement, and that, *pari passu*, they must become affiliated to general hospitals and schools—the reverse of Dr. Goodall's suggestion that the place where early mental patients are to be treated must be entirely "divorced" from the mental hospital. The mental hospital needs the help of the general hospital and its staff, its boundless opportunities for educational development and advanced treatment.

I venture also to think that the general hospital will have some need of the mental hospital, and that the "galaxy" will be glad to feel that when their failures need treatment in a mental hospital that treatment will be "the most effective treatment."

It is even conceivable that when more enlightened notions prevail, as they do in some other countries, it will really be possible to secure the most effective treatment in any mental hospital, even in this land of ignorant prejudice, where one of the deepest roots of the whole trouble lies in the false stigma attached to insanity. At any rate, the realization of this is the aim of those who, like myself, venture to have faith in the progressive evolution of the mental hospital, and in the development of a more intelligent attitude of public opinion.

Psychiatrists were among the first to study the question of clinics and to advocate the treatment of incipient cases in such clinics; and if now it is advocated that owing to present needs, economic and otherwise, mental hospitals shall develop separate admission units, run on hospital lines and free from association with protracted insanity, where effective

treatment will be available, and from which, it may be, cases recovering will be discharged to central clinics or convalescent homes, this in no sense would imply any opposition whatever to the greatest possible concentration on treatment and research in close association with medical schools, and under the guidance of "the high priests of medicine," nor would it run in opposition to the treatment of paying patients in private hostels.

So far from being "divorced" from mental hospitals, central clinics will in many ways require the co-operation and help of the mental hospitals without which the problems connected with the treatment and care of the majority of the mentally afflicted cannot be successfully solved.

Dr. Goodall's letter widens, instead of narrowing, the gulf which separates the mental hospital from participation with the school in a combined movement towards a better understanding and treatment of mental disease, by implying that the former should be excluded from the hospital orb.—I am, etc.,

G. F. BARHAM.

London County Mental Hospital,  
Claybury, March 28th.

#### TREATMENT OF EARLY MENTAL CASES.

SIR,—I was surprised to read in Sir Bryan Donkin's letter in your issue of April 7th (p. 611) the following: "Of course it is a well known fact that 'mental' patients of all sorts and degrees dread the thought of being sent to a mental institution by whatever name it may be called." My experience does not coincide with this statement. In institutions such as Bethlem Royal Hospital in London and Morningside in Edinburgh, the numbers of voluntary patients often exceed those who are "certified."

During the year 1921 (Board of Control Report) registered hospitals in England and Wales admitted 330 voluntary boarders, and licensed houses (better known as private asylums) admitted 315 voluntary boarders. I have numbers of applications to receive patients here on a voluntary basis, but I cannot do so as this is technically a "borough asylum," and no county or borough asylum can receive "voluntary boarders." In one instance a woman was so desirous to come for treatment that when she found she could not be admitted on her own application she persuaded two doctors to give certificates. Quite recently a girl who was out on trial evaded the vigilance of her relatives and returned here. Only last Friday I saw a man at King's College Hospital suffering from melancholia with suicidal thoughts, and he begged to be admitted into a mental hospital. I must admit that there are numbers of patients with no insight who think there is nothing the matter with them, and are therefore unwilling to enter a hospital of any kind, mental or general. On the other hand, newspaper correspondence under the above or similar headings often fails to take into account the large numbers of mental cases anxious for treatment in a mental institution.—I am, etc.,

City of London Mental Hospital,  
Dartford, Kent, April 9th.

R. H. STEEN.

SIR,—Why does Dr. S. E. White impute false motives to the "lunacy authorities," and that not for the first time? By what obsession is she influenced which obstructs her judgement? These questions naturally arise on reading the statement in her letter that—

The "Health Minister is led by the lunacy authorities to frame a bill which, under the specious title of 'Reform in Lunacy,' is intended to diminish or annul the safeguards provided by the Lunacy Act, and to set up institutions . . . which shall serve as feeders to asylums."

Dr. White herself advocates "homes or hostels" or "suitable sanatoriums for early cases as an alternative to asylums." She herself wishes to set up such institutions as alternatives to asylums, without providing any safeguards whatever or any means of protecting the mentally affected patients in them from the danger of being exploited by designing persons. Let her cast out first the beam out of her own eye before she presumes to pass judgement on others! The mote she now beholds may then be found not to exist.

In the second place, it is false to say of any institutions that may be set up under a bill, that they "shall serve as feeders to asylums." If they serve any purpose of this kind at all it will be not to feed but to starve asylums. All this is as plain as a pikestaff to any unbiased person.

Sir, is it not time that this correspondent, despite her name, ceased to call white black, and black white?—I am, etc.,

March 25th.

### THE INFLUENCE OF INTESTINAL BACTERIA UPON THE THYROID GLAND.

SIR,—I read with interest the article on this subject by Dr. Harries (March 31st, p. 553). The view that exophthalmic goitre is in part dependent on excessive absorption of tryptophane owing to a deficiency of tryptophane-splitting organisms in the intestine is one which I have held and taught for several years. The theory, moreover, is in my view capable of considerably wider application and explains many of the abnormal conditions affecting the internal secretions. In a paper read before the Medical Society of London in 1912 as part of a discussion on alimentary toxæmia<sup>1</sup> I pointed out that the view that the evidences of suprarenal deficiency so often seen in intestinal stasis depended on excessive destruction of tyrosin by the intestinal organisms and a consequent deficient supply of the precursor of adrenaline to the suprarenal. I also suggested that the same explanation probably held in regard to other glands and substances, instancing tryptophane. This was before Kendall's isolation of thyroxin and before its formula had shown that tryptophane is the direct precursor of the thyroid secretion.

It seems probable that all the internal secretions are normally elaborated by the glands from certain definite amino-acids resulting from protein digestion, and that the amount of internal secretion formed depends, within limits, upon the amount of precursor available. The regulating mechanism of the absorption of the precursor from the gut would appear to be the intestinal flora; and an excess of bacterial activity will lead to a deficient absorption, just as a diminution of organisms will lead to an excessive absorption. The fact, which is becoming increasingly clear, that exophthalmic goitre is not primarily a disease of the thyroid gland, but is a polyglandular syndrome affecting especially the suprarenal and the thyroid secretions, is thus explained on a common hypothesis, and one which bears that hall-mark of truth, simplicity. The rationale of thyroid surgery in exophthalmic goitre is that, since at present one cannot control the supply of fuel, one can at least shut down a proportion of the furnaces, or in other words one can limit by thyroidectomy the extent to which an excess of tryptophane can be turned into thyroxin. Finally, I note that Dr. Harries states that in operating for exophthalmic goitre he removes "about half the gland" and that thereby "the symptoms will be reduced for a few months." This is a result which is far less than surgery can and does bring about, and I would emphasize that it is seldom enough to remove half the gland. The whole of one lobe, the isthmus, and from one-half to two-thirds of the other lobe, must usually be removed if the full and striking relief which operation offers is to follow.—I am, etc.,

London, W., March 31st.

E. G. SLESINGER.

SIR,—The lucid and awakening paper of Dr. Harries makes one ask wherein lies the action of iodine given internally for parenchymatous goitre? Is it likely, in his opinion, to affect directly the chemistry of tryptophane and indican? Mine is a rural practice on chalk. Parenchymatous goitre is common, and I have not yet seen one fail to react beneficially to iodine.—I am, etc.,

Salisbury, March 30th.

G. C. ADENEY.

### IONIC MEDICATION.

SIR,—Dr. Campbell's paper on ionic medication (BRITISH MEDICAL JOURNAL, March 10th, p. 409) should arouse general interest in the matter that is sadly lacking. During the four years that I have been working at it I have got results that cannot be made to tally with his deductions. There is no doubt that some of the ions that are being introduced are "whisked off in the blood stream" as soon as they get through the skin, and some will combine with tissue elements at the electrode (as with zinc and chlorine, forming zinc chloride), but only some. The main volume of electric ions will pass on into deeper structures, carrying their corresponding medicinal ions with them until their impulsive force is overcome by the resistance of the structures, and to complete the journey which they must perform to the opposite pole they then go on alone and from that point become a simple electric current. Accepting the old tag that "an ounce of fact is worth a ton of theory" as I do, let me give some cases that may be looked upon as facts.

Both knee-joints (my own) were affected by gouty arthritis, on and off, for a considerable but unnoted period. At the end of January, 1919, the left had become so bad that only a few steps could be taken before the pain became unbearable. An x-ray photograph showed a number of osteophytes, massed adhesions, and erosion of the articular surface of the patella. The joint was put under ionization at the beginning of February with potassium iodide. After the second application I walked on an uneven road for over an hour in complete comfort. The treatment was continued regularly for a month, less regularly for the next month, and occasionally in the third month. In May an x-ray examination showed no osteophytes or adhesions and an apparently normal patella. If the iodine ions did not cause the absorption, what did?

Again, a case was admitted to the infirmary of cancer of the rectum, extending as far as the finger could reach and all the part around the anus. The patient was treated with zinc ions from a large pad which covered the whole growth, but did not enter the anus. At the end of fifteen months the outer parts were healed and no growth could be found in the rectum. There could be no doubt about deep penetration there.

The next case will be seen to provide a positive proof in its first and a negative in its second stages—cancer of the tail of the pancreas. An exploratory opening of the abdomen was closed up and the patient came home to die, the malignant mass being the size of a large lemon. He was treated with zinc ions, with the result that the growth became steadily smaller until at the end of seven months it could not be felt. He then rapidly put on fat, which, being non-conducting, established an impermeable barrier to the current, which passed to the opposite pole by the superficial parietal layers, and the growth increased quickly to its former size. By that time, assisted by appropriate dieting, the fat had disappeared, and then the mass again lessened by about half; by this time secondary growths had appeared in the stomach and liver, and the patient died, having lived fifteen months after the operation.

One more case showing deep penetration—enlarged cervical glands. A pad moistened with a solution of potassium iodide was placed over the glands and within two seconds the patient said he experienced a "coppery taste." This distinctive taste of potassium iodide could not have reached the tongue and palate in the time, if conveyed there by the circulation, and must have been caused by iodine ions that had been carried through all the neck structures of that side. This case seems to prove that the diffusion of the medicinal ions is not only fairly deep but is limited in area, otherwise we should expect to find the typical symptoms of iodism that were so common fifty years ago—in the days of small doses.

My own experience goes to prove that we are able to apply certain remedies to a localized area by means of ionization, with results that could not be obtained through the circulation without affecting the general system. Take, for instance, a case of sciatica. Under salicylic acid (whether as sodium salicylate or aspirin) given by the mouth, by the time the pain was conquered there would be the usual symptoms of tinnitus and so on. With solution of sodium salicylate by ionization I have seen no symptom appear beyond a total disappearance of pain with one application lasting thirty minutes.

In practising ionization it is of the utmost importance to be sure of correct technique. Given that, I am sure that good results can always be obtained; if it had received as much attention at the hands of the profession as has been accorded to such follies as removing adenoids, tonsils, and prepuces it would by now have been an acknowledged and generally used method.—I am, etc.,

Bishop Auckland, March 14th.

MARK WARDLE.

SIR,—Dr. Campbell frankly states that he has had no experience with ionic medication in the cure of local surgical disease; but lest his researches in the purely medical domain should be confused with those cases of a surgical nature, due to local septic conditions, where the organisms or their spores are so deeply placed in the tissues that no amount of local antiseptic treatment avails, I wish to give testimony to the enormous value I find in this treatment. It is over twenty years ago (speaking from memory) since I first saw the wonderful results obtained by my friend the late Dr. Samuel Sloan in septic conditions of the uterus and cervix and adjacent tissues by means of ionization, using copper ions.

I realized that if such results could be had in his specialty, it should be possible to get the same in mine (the mouth and teeth). Since then I have used constantly this method in all septic conditions of the gums and teeth. Where I want a sedative antiseptic result I use iodine locally with negative pole, and where I desire a more powerful (and incidentally a trifle irritating) antiseptic I use zinc, either as zinc chloride or zinc sulphate solution.

What I desire to emphasize is that the results are always excellent, sometimes wonderful. I would find the loss of this method of treatment a very serious one indeed. X-ray

<sup>1</sup> And the Boston Medical and Surgical Journal, vol. clix, No. 1, 1913.

findings as to septic foci about the tooth roots lose their significance when ionization can be successfully used and a cure effected.—I am, etc.,  
Glasgow, March 25th.

DAVID FYFE, M.D., F.R.C.S.

SIR,—The question of ionic medication and the introduction of ions from without into the deeper parts of the body crops up from time to time and Dr. Campbell's paper on this subject (March 10th, p. 409) will be welcomed, but it is liable to be misleading, because, to those not familiar with the present-day teaching, it may appear that he has shown to be without foundation and worthless a method of treatment which is commonly practised and taught by recognized teachers of electrotherapy. This is not so, because, as far as it concerns medical ionization, he is simply repeating what amounts to the commonly accepted doctrines on this subject.

When, however, the author gets beyond the limits comprised within the term "medical ionization"—that is, the introduction of ions from without—there are certain aspects of the question about which there will not be the same agreement.

It cannot be doubted that there are chemical changes in the interpolar regions as a result of ionic movements under an applied electromotive force. Dr. Campbell admits this, whether he intends to do so or not, when he says that stimulation of coils beneath the skin occurs. It is admitted that "the passage of an electric current through the tissues will have a general stimulating effect upon them." This effect must be due to either physical or chemical changes, the result of the current.

Chemical changes take place at the poles, and virtual poles exist at each situation where ionic concentration varies. In the tissues and fluids of the body we have not to deal with an electrolyte consisting of one salt only, as in Dr. Campbell's example and in the experiment of Faraday to which he refers. The current in the body is carried by ions of different ionic velocity and variations in velocity of the ions will produce variation in chemical composition. Stimulation by direct current is due to chemical change and the chemical change is due to ionic movement. Dr. Campbell admits that stimulation of tissues occurs, but says it is not due to chemical changes. What, then, is it due to? It is not sufficient to say merely that it is due to the passage of the current.

Dr. Campbell seems to have been unfortunate with his cases, but without more details of their etiology and characteristics and of his technique little can be said to throw light upon the cause of his failures, except that the cases were evidently unsuitable for the treatment. In rheumatoid arthritis permanent benefit cannot be expected from direct current if the original focus of infection is still in existence, though it undoubtedly influences the resolution of the peri-articular deposit and synovial swelling when the focus has been removed.

Some cases of sciatica, brachial neuritis, trigeminal neuralgia, etc., will get permanently well with the use of sodium salicylate or quinine sulphate solution to moisten the pads, although direct current applied with solution of sodium chloride has been used previously without benefit. This happens fairly frequently in cases of trigeminal neuralgia.

The so-called lytic effect is well known to exist. The softening of scars, the resolution of fibrous deposits and the absorption of exudates are produced and hastened by the action of direct current. The mode of action of the current and whether it occurs more readily under the anode or the cathode are proper subjects for discussion, but that the action does occur is well known and must be recognized.

Whether the results of the direct current upon morbid conditions are obtained or not by one or other method of direct current application is a matter of clinical experience. Dr. Campbell has given neither clinical details of the cases which were the subject of his investigation nor details of his technique in applying the currents.—I am, etc.,

Isleworth, March 27th.

#### TREATMENT OF PUERPERAL INFECTIONS.

SIR,—Professor Watson's article on the above subject (March 24th, p. 505) is interesting, and he is to be congratulated on his results.

As a clinical bacteriologist I often get cases of this type to investigate, and I find the most prevalent bacteria are those mentioned by Professor Watson; I would, however, add one more—*Micrococcus tetragenus*. Now these are bacteria

which are associated with chronic infections, and if we exclude gross contamination by midwife or medical attendant, which, I think, can be done in a very large proportion of cases, we have still got to explain what has set up the acute condition.

Some cases of tuberculosis after pregnancy and confinement take on an acute phase, and we do not look for a cause or blame ourselves for causing the infection. We believe that the stress and strain of pregnancy and childbirth have in some way upset the balance and given the chronic tubercle its chance. If, then, we argue in this way in one chronic infection why should we not do so in others?

A careful bacteriological examination of the urine of pregnant women in the last months of pregnancy would in many cases reveal some chronic infection. If we did not believe in the use of prophylactic vaccines, the examination would still be useful, for it would help to put us on our guard and it would show, or help to show, whether we were dealing with a chronic infection lit up by the confinement or a fresh infection from outside. If medical officers of maternity hospitals took up the question of puerperal infection from this standpoint it would, I feel certain, be a step in the right direction, and might even help in solving the riddle of puerperal septicaemia.—I am, etc.,  
J. L. RENTOUL, M.B.

Belfast, March 25th.

#### "ATHLETIC HEART."

SIR,—It is significant that a physician of Dr. G. A. Sutherland's reputation, in writing upon the "athletic heart" (BRITISH MEDICAL JOURNAL, March 24th, p. 496), is not prepared, even with the recollection of his own profound experience, to deny categorically "the possibility of a healthy youth producing a condition of injurious strain in his own heart." Perhaps it may be urged that only a rash or very foolish person categorically denies anything, more especially a possibility of this character, which would seem to be the most reasonable view to take on *a priori* grounds. And so the expression "strain" or "overstrain" still flourishes enshrined in cardiology and undisturbed even by the *ex cathedra* pronouncements of eminent authorities. Yet, when one hears that Dr. Sutherland has never met with a case of "strained heart," and remembers that Sir James Mackenzie has "personally never seen such a thing," and that Sir Thomas Lewis, in his *Clinical Disorders of the Heart Beat*, expresses the same view, it need not perhaps be regarded as an act of very great temerity for a junior first to include himself in such good company and then to go further than any of them in a dogmatic denial of "athletic heart."

If one is willing to accept as evidence of "cardiac strain" any of the various symptoms which may follow upon a severe physical effort, then the "athlete's heart" may be encountered in great profusion. The boy or young man who has been completely run out, or rowed out, may suffer more or less severely according to his fibre from symptoms which, as Dr. Sutherland points out, are referable to the vasomotor system. And it may well be that the best corrective for such instability is not the sedulous care directed to the heart as if it were a bomb ready to explode, but another exhortation to exertion.

It is some sixteen years ago, but I recollect to this day the appalling disturbances ensuing upon a hard two hundred yards race, culminating in nausea, persistent dyspnoea, and dreadful headache, which persisted for the rest of the day. As this occurred in the middle of what was to me a very important athletic season, I adopted a "try out" of crucial significance, and next day ran, with very great relief to my doubts, one of the best quarter miles I have ever run. It may be said that to continue athletics in the face of such contraindications was the act of a fool. Yet I find myself, after twenty-one years of almost continuous competition, a good deal slower it is true, but more, not less, capable of prolonged exertion. I could recall some extraordinary opportunities of incurring "heart strain" when all circumstances were favourable thereto, but it would be trivial to indulge in further personal reminiscences.

Of the cases referred to one as suffering from heart strain, a few, as Dr. Sutherland points out, actually afford evidence of an organically damaged heart the symptoms of which have remained latent until a breakdown occurred. A considerable number have sought advice on an anxious parent's natural solicitude at the exhibition of some such symptoms following exertion as I have described in a personal experience, and who have been condemned by a doctor with a whole-hearted belief in the malevolence of athletics or on

account of his discovery of such a peculiarity as sinus arrhythmia. Not a few correspond to a type temperamentally and constitutionally unfitted for physical exertion—"faint-hearted"—in the spiritual sense. I am most interested to see that Dr. Sutherland refers to these as candidates for "soldier's heart," a pathological opinion which I maintained at a time when "soldier's heart" was on the crest of its popularity.

It may be objected—and an eminent physician for whom I have the greatest respect and admiration has employed this argument—why should the heart enjoy as a monopoly this immunity from becoming strained? I think Dr. Sutherland answers such a question, even if his answer begs the question. The heart enjoys such a monopoly because it is indispensable as a survival factor that it should be so privileged, and with a large measure of reserve is defended by the breakdown of less vital structures. Even if one conceives of some permanent strain following exertion, I should not allocate such strain to the heart but to the body as a whole. For it seems to me that too much attention has been centred upon the heart; yet the thing which makes a man an athlete is the perfect co-ordination of muscles, respiration, circulation, and so on, and if strain ensued as a result of exertion I should picture such strain as a breakdown in co-ordination, the cardiac element being the least of all concerned.—I am, etc.,

London, W., March 29th.

ADOLPHE ABRAHAM.

SIR,—In the BRITISH MEDICAL JOURNAL of March 24th Dr. Sutherland, writing under the "athletic heart" (p. 497), throws doubt on the possibility of a healthy young heart being strained, and says he has never met with such a case, and that in cases of heart breakdown there was always some predisposing cause such as organic disease. He recalls a case of a young miner who was said to have injured his heart by lifting a heavy piece of coal, but when seen it turned out that he had a marked mitral stenosis.

Dr. Sutherland goes on to say: "By no stretch of imagination can mitral stenosis be induced by physical strain." Quite so, but a murmur simulating the condition may be produced by cardiac dilatation. (See chapter on "The relation between cardiac dilatation and heart murmurs" in my work on asthma published some years ago.) Again, he writes: "Perhaps it is dilatation of the heart that crops up most frequently as the result of this so-called heart strain. Now dilatation of the heart is an evidence not of strength but of weakness." Precisely, but a tired heart is a weak heart, and the heart even of a trained athlete can become tired. The overstrain is caused by the individual persisting in his efforts, after Nature tells him he has done enough, by sheer will power. Now a strained heart tends to become dilated, as the following example will show:

After a certain severely contested boat race at Henley "bow saw red, 2 went blue, 3 fainted, and stroke fell out of the boat." On percussing the heart of No. 2 I found the left heart margin to be well outside the mid-axillary line. After some rest and brandy the heart returned to its normal dimensions in about half an hour, but, had it not quite done so, a degree of chronic dilatation would have become established, which might only make itself felt years afterwards.

By "athletic heart" I presume is meant what is well known to the public as an "athlete's heart." Every normal heart is athletic—remarkably so. From the time we are born until we die it never ceases to beat night or day.

In a lay paper a year or two ago appeared an article signed "A Professor of Medicine" in which an eminent authority on the heart was quoted as having said that the athletic heart was a "figment of the imagination." On writing to Sir James Mackenzie asking for his opinion on the question, his reply was as follows:

"My views on the athletic heart correspond to those of Dr. Sutherland as expressed on page 497 in the BRITISH MEDICAL JOURNAL of March 24th, 1923."

I consider that to ignore the possibility of heart strain in the healthy heart, owing to physical indiscretions, is to hold a very dangerous doctrine indeed, as I have come across many cases in my practice who have suffered from the after-effects of such indiscretions such as fatty heart, emphysema, asthma, and angina pectoris. I have been and still am somewhat of an athlete myself. I have found when mountaineering that if one climbs too strenuously in the Alps, even although the heart is perfectly normal and strong, one is apt to acquire some cardiac dilatation accompanied by swollen ankles and albuminuria from prolonged walking uphill, especially over deep snow, and when out of breath.

If this be not due to heart strain I do not know what is. This condition passes off, as a rule, after a few days' rest in the valley. But sometimes it does not, and a state of chronic cardiac dilatation is established which would require special treatment in order for it to be dispersed. Many a man's climbing career has been cut short in this manner, and he has never climbed again.—I am, etc.,

London, W., April 3rd.

ERNEST KINGSCOTE.

### HOSPITAL POLICY.

SIR,—What a marvellous success is the Oxford Contributory Hospital Scheme! Dr. Collier may well feel proud. No more anxiety about how to support our voluntary hospitals. What a docile population is ours! They all contribute their 2d. or 3d. a week regularly, just as if it were for a hospital club or an insurance against the need of surgical treatment. There is no contract. They still remain objects of charity, and the voluntary hospital staff can attend them just on their own terms.

Well, are not our people wonderful? They provide the material for hospital experience and teaching, and then we use that in our nursing homes and private wards to make money out of "their betters." Why talk of paying hospital staffs? We will be paid as long as appendectomies and circumcisions are necessary or fashionable. Of course, some private practitioners will be hit. I heard of one such the other day. He and a midwife arranged to do circumcisions. She provided the "nursing home" in her cottage. Sunday was operating day. They divided 30s. a case between them; the doctor took the sovereign and was quite satisfied.

I suppose the Oxfordshire workers do not demand representation on the board of management of the Radcliffe Infirmary? Anyhow, it is not worth while bothering about paying hospital staffs. You see, it might unsettle the minds of the lay board, and they might begin to talk about efficiency, regular attendance, etc., if they were not so lay.

It is grand. No more worry about how to finance our voluntary hospitals. Because if the workmen do not pay up—well, it can be deducted from their wages.

Did not the club system end in national health insurance? Which do we prefer—Friendly Society control or State control? If the gods wish to destroy us they first make us mad.—I am, etc.,

Helston, March 25th.

FERDINAND REES, M.D.

### THE MNEMIC PRINCIPLE.

SIR,—I have read with care Sir Frederick Mott's article on the "mnemonic principle" in your issue of February 24th, but after close study I am bound to say that the illumination I received was by no means proportionate to the attention I gave. Discussions of psychology founded on biological data, such as here exhibited, remind me of the disquisitions of the Schoolmen on mechanics before Galileo arrived to lay down a true foundation of the science and to point the way to development.

Speaking dogmatically, but simply for the sake of brevity, I say that to start by positing three primal instincts as the basis of a study of psychology has its analogue in the disquisitions on proper and improper motion or the nature of centrifugal force. The propositions set forth can hardly be grappled with; they are neither true nor false; they do not pose the problem in the proper manner at all. Where they appear profound and scientific they amount to garnishing familiar notions with new coined technical terms. Beyond that there is no closely consecutive developmental argument, but merely clothing a descriptive form with pedantic symbols.

The instance given to show that painful stimuli have a more powerful influence than pleasurable is unscientific, in that out of phenomena which depend on a multitude of factors, of which the freshness and intensity of the stimuli may be noted particularly, Semon selects but one, and draws conclusions which are not only not warranted by the argument but are not true. I speak here with complete confidence; for many years I conducted a series of experiments in memory, controlled where possible by quantitative determinations, and these, though extremely laborious, permitted me to obtain certain definite results.

I could criticize paragraph by paragraph, but that is not necessary, for this so-called mnemonic principle is, as a basis of a scientific psychology, quite illusory. The true principle consists in laying the foundation at the level of the most rudimentary psychic processes, and thence proceeding by

closely consecutive, rigorous reasonings up to definite conclusions. This involves, of course, the discovery of a mode of analysis which will yield us the fundamental processes by whose combinations the whole world of thought may be exhibited. That work has been carried out. Again I speak with assurance, because I do not depend on the support of any authority, but on the rigorous, inevitable character of the arguments I have introduced. I have not been content with this foundation. I have thrown in, as a piece of artistry, a demonstration that by no other route, in its ultimate course, could this exposition of the fundamental processes be attained.

Also I have examined in a new light some of the famous "positions" of philosophy and psychology, and amongst these that of memory. I have also shown, contrary to what one would gather from Sir Frederick Mott's article, the influence of heredity and of habit; I have demonstrated, again with experiments quantitatively expressed, the influence of habit, and in a manner both more precise and more fertile, in the sense of development, than he will find in Semon's mnemonic theory, or in the writing of those others whom he quotes as authorities.—I am, etc.,

London, N.W., March 12th.

ARTHUR LYNCH.

### MEDICAL PHYSICS IN THE CURRICULUM.

SIR,—We desire to bring before your readers our views on the teaching of medical physics in the later years of the course. We understand that it is suggested in Edinburgh that the student might obtain some teaching of medical physics from the physiologist, some from the ophthalmologist, some from the laryngologist, etc.; but we are of opinion that unless a definite course by a definite teacher, who is qualified to teach medical physics, is attended, and unless this is followed by a definite examination ad hoc, the subject would not receive the study and attention which it deserves. The information would be patchy, important points would inevitably be omitted, and the instruction would lack the consecutive and coherent character which is essential for an efficient course.—We are, etc.,

ALFRED DANIELL, M.A., LL.B., D.Sc.,

DAWSON TURNER, B.A., M.D., F.R.C.P.E.,

M.R.C.P.Lond.,

WILLIAM GEORGE SYN, M.D., F.R.C.S.E.,

Examiners in Physics for the Triple Qualification.

Edinburgh, March 31st.

### A MEMORIAL TO ARTHUR BACOT.

SIR,—It is just a year since Mr. Arthur William Bacot's name was added to the long roll of martyrs of medical science. It is quite unnecessary and, on the part of a personal friend, would even be indelicate to attempt to add anything to what has already been said respecting Mr. Bacot's services to preventive medicine, but there is a peculiarity in his case which is worthy of commemoration.

Most men, certainly most medical men, cannot but be appalled by the complexity of modern scientific research, the vast amount of special training which seems to be an indispensable preliminary of any hopeful attempt to extend the bounds of knowledge. This feeling, almost as much perhaps as lack of time and opportunity, has discouraged research in general medical practice. But Mr. Bacot's case is one of those instances which prove that very fine work can be done with but a slender technical outfit. Mr. Bacot's scientific education, in the formal sense, was immensely inferior to that of the worst taught medical student in the country, yet before 1911, before he enjoyed the advantages of a whole-time research post in a properly equipped institution, he had carried out a piece of first-rate medico-entomological work.

The sole educational foundation of Mr. Bacot's work was a knowledge which is part of the curriculum of all pupils in our modern elementary schools, nature study, and he regarded training in that study as the most valuable of all teaching.

Even nature study involves some outlay. To foster and turn to good ends the child's collecting instinct imposes on the teacher a little expenditure upon the impedimenta of a school museum. Even a herbarium requires material.

This is no time to pester people for subscriptions to memorials however worthy the object. But some of Bacot's personal friends and neighbours have thought that the collection of a small sum of money, to be called the "Bacot Memorial Fund," the interest on which, whether a few

shillings or a few pounds, would be placed at the disposal of the local (Loughton) Council Schools for the assistance of nature study teaching, might not be too ambitious. Should any reader of the JOURNAL care to contribute a few shillings to this object, subscriptions would be gladly received either by me or by the treasurer, Mr. Hubert Baines, C.B.E., Bryn Mawr, Church Hill, Loughton.—I am, etc.,

Loughton, April 4th.

MAJOR GREENWOOD.

### THYMIC ASTHMA: A PROTEST.

SIR,—In the February number of the *Archives of Pediatrics* there appeared an article written by me on "Thymic asthma"; it was written especially for the British number of that journal. On March 21st the article appeared verbatim in a London medical paper, transferred bodily without authority and without my knowledge, though the source was indicated in a footnote. I wrote at once to the editor demanding an explanation and an apology for this act of piracy, and although it is now nearly a fortnight ago my letter remains unanswered and unacknowledged.

I protest against such a proceeding. It places me in an odious position. I must apologize to the editor of the *Archives* for a robbery in which I had no part; it leaves me under the suspicion of an attempt to broadcast my literary efforts after a fashion which I have always heartily condemned; and, not least distasteful, of contributing to a paper for which I have always felt a profound contempt. Yet, even from such a paper, I confess that I had not expected the addition of insult to injury by the failure even to acknowledge my letter of protest.—I am, etc.,

London, W., April 5th.

HUGH THURSFIELD.

### Obituary.

ROBERT JOHNSTON, M.D.,

Portrush.

On March 24th there passed away a personality well known throughout the North of Ireland, Dr. Robert Johnston of Portrush, the younger son of the late Dr. David Johnston of Belfast.

Graduating M.B., B.Ch., B.A.O. in 1904 in the Royal University of Ireland after a successful student career at the Belfast School of Medicine, Johnston held the resident posts at the Royal Victoria Hospital, where he almost at once showed evidence, not only of his clinical instinct in the diagnosis of disease, but also of a tendency to rheumatic affections which were soon to cripple his professional work and eventually cause an early death. Leaving the Royal he became resident medical officer at the Belfast Maternity Hospital, and in a comparatively short time his enthusiasm and his devotion to hard work made him a master in the obstetric art and gave him opportunities for the performance of almost every obstetric operation. The irregular hours and the wide limits of the practice attached to this hospital produced within a brief period their effect on his health, and on the advice of the late Dr. McQuitty he gave up this appointment and took a prolonged holiday at sea. On medical advice also he relinquished his intention of specializing in obstetrics and disease of women as beyond his physical capabilities. He therefore became house-surgeon at the Liverpool Eye and Ear Infirmary, Myrtle Street. After he had worked there for six months, exhibiting marked administrative capacity with unusual operative dexterity, the visiting staff did him the honour of asking him to accept a post on the staff. His health, however, did not justify him in accepting the offer, though it was with great regret that he refused. In 1909 he proceeded M.D., and soon afterwards settled in Portrush where for some years he had a large consulting practice in ophthalmic and aural surgery. In recent years his practice had been greatly curtailed by long periods of grave disability, and for many months previous to his death he had been unable to go up or down stairs.

A colleague writes: It would not be easy to state wherein Johnston gained his undoubted hold on his patients or his friends. Abrupt, at times even brusque in manner, he yet gained the affection and respect of both. He had a clearness of vision, a unity of purpose, and an unerring clinical instinct which inspired confidence. In recent years he was universally visited by the younger medical men on holiday in Portrush, and few ever came away without having added to their store of

knowledge. Whether the conversation turned on his own specialty, medicine or surgery in general, military or naval policy in the war, or motor cars, Johnston was invariably well informed, and never hesitated to express his views tersely and without hesitation or excuse. Johnston was upright and sincere to a fault, if that be possible. Diplomacy in private life or in professional work he neither used nor countenanced. His cheeriness and friendliness, his optimism in spite of a clear view of his own prospect of life, were alike the wonder and the admiration of visitors, many of whom will miss him for years to come. He is worthy to be placed in the category with his teachers, Robert Campbell and William McQuitty, too early gone to their reward, leaving a rich memory to their friends, and to their school an irreparable loss.

DANIEL B. BALDING, F.R.C.S.,  
Royston.

THE death of Mr. D. B. Balding, of Royston, at the ripe age of 92, is reported elsewhere in this issue. He received his medical education at the Middlesex Hospital and took the diploma of L.S.A. in 1852 and that of M.R.C.S. in 1853. He became F.R.C.S. Eng. in June, 1858. He was the oldest Fellow with the exception of Mr. T. Pridgin Teale, of Leeds, who took the diploma on May 23rd, 1857, and who continues to follow the progress of medicine and surgery from his retreat near Leeds. After acting as resident medical officer at his old hospital, Mr. Balding began to practise at Royston, where he was medical superintendent of the hospital. He was coroner for Hertfordshire for more than forty years, and was very well known throughout the counties of Cambridgeshire and Hertfordshire, in both of which he was justice of the peace. He had served with the first Hertfordshire Volunteer Regiment, attaining the rank of surgeon lieutenant-colonel and receiving the Volunteer Decoration.

He was long a loyal member of the British Medical Association, and had been president of the Cambridge and Huntingdon Branch. For many years he represented the interests of the Poor Law medical officers on the Parliamentary Bills Committee of the British Medical Association, and was also for some time President of the Poor Law Medical Officers' Association. He was an adviser and frequent contributor to this JOURNAL on Poor Law matters. In early life he was associated in this work with Dr. Joseph Rogers, and strenuously maintained the principles which that remarkable man enunciated. Mr. Balding was in his prime a big burly man, with a genial manner and generous heart, which combined with his obvious sincerity to endear him to all who were associated with him in the crusade for the betterment of Poor Law conditions, both for doctors and patients, which was his chief life work, and owed so much of its success to his energy and tenacity.

THE death of Dr. T. A. MURRAY of Penketh, near Warrington, took place somewhat suddenly on March 21st; he had been in ill health for eighteen months, but his cheerful manner kept his trouble hidden even from his friends. At midnight on the 19th he had a severe heart attack; he recovered, and insisted on doing a full day's work on the 20th, but during the night had another attack, which proved fatal. Thomas Alexander Murray was born 61 years ago at Levenshulme, near Manchester; he was educated at the Manchester Grammar School, the Owens College, and the Manchester Royal Infirmary. He obtained the L.R.C.P.I. in 1887, and started practice in Penketh in 1889; this village was up to then dependent on the doctors from Warrington, but he soon established a very large and wide practice. Shortly after qualifying he joined the British Medical Association, and had always been an enthusiastic member; for many years (about sixteen), and at the time of his death, he was honorary secretary to the Warrington Division, never missing a meeting whatever the weather, although he lived three miles from Warrington. He was the first secretary of the Warrington Panel Committee, and held that post for seven or eight years. During the war he was for a long time—and after the armistice—a visiting physician at the Lord Derby War Hospital (Winwick Asylum, near Warrington) which meant a six miles' journey each way from his residence; this journey he often did twice a day in addition to carrying on his large practice. He was also a member of the National Service Medical Board, and since the war he has been a chairman of the Pensions Medical Board. In addition to his medical work he entered into the village life: he held or had held

such posts as chairman of the Old People's Treat, manager of the Council School, chairman of the Warrington Rural District Council, and member of the Warrington Board of Guardians. Some ten years ago he resigned from the Rural District Council and was appointed medical officer of health, and continued to act in his usual thorough manner until his death. To the foregoing particulars Dr. E. E. Bowden adds: "Among his professional brethren Dr. Murray was highly respected; he was conspicuously honest and straightforward, and while he was never known to do an unkind act, he did many kind ones. His funeral on March 24th was attended by large numbers of villagers (his patients) and representatives of the Rural District Council, Warrington Insurance Committee, personal friends, and nearly all the medical practitioners and dentists of Warrington and district."

WE regret to record the death at Kelso, on March 21st, of Dr. GEORGE MCKELLAR, medical officer of health of the burghs of Hawick, Kelso, and Selkirk. Dr. McKellar received his medical education at Edinburgh University, and graduated M.B., C.M. in 1896, and M.D. (with high commendation) in 1898; he took the D.P.H. in 1897. He was house-surgeon in the eye wards of the Edinburgh Royal Infirmary, and subsequently assistant ophthalmic surgeon at the British Ophthalmic Hospital, Jerusalem. He went to Kelso twenty-two years ago, and, besides holding the appointments mentioned, he was also school medical officer of Hawick and a medical officer of Kelso Cottage Hospital. For some years he was chairman of Kelso School Board, maintaining to the end a keen interest in educational matters. He was a Fellow of the Edinburgh Obstetrical Society and an old member of the British Medical Association. He formerly held a commission in the R.A.M.C. (T.F.), retiring with the rank of captain; during the war he was commandant of the local detachment of the V.A.D. Whatever interested him Dr. McKellar took up with enthusiasm; he was a man of strong and forceful personality, yet with a kindly, sympathetic disposition.

DR. CARL SPENGLER, a Swiss authority on tuberculosis, has recently died at Davos at the age of 64.

## Universities and Colleges.

### UNIVERSITY OF LONDON.

#### Meeting of the Senate.

A MEETING of the Senate was held on March 21st. The resignation on the ground on ill health by Professor W. D. Halliburton of the University chair of physiology at King's College was accepted as from July 31st, 1923.

It was reported that the King and Queen had consented to lay the foundation stones of the new buildings provided by the Rockefeller Trustees in connexion with University College and University College Hospital Medical School at the latter part of May, and that on the conclusion of the ceremony their Majesties would visit and inspect the new anatomy building.

The Senate approved revised regulations in medicine for internal and external students; they will apply to all internal students who commence their courses of study for any of the examinations leading to medical degrees in or after October, 1923, and to external students in respect of the following examinations: (1) first medical examination in and after July, 1924; (2) second medical examination in and after July, 1924; (3) Part I, in and after March, 1924; (4) Part II, in and after March, 1925; (5) M.B., B.S. examination in and after October, 1926. Copies of the revised regulations may be obtained in due course on application to the Academic Registrar or the External Registrar.

The regulations for exemptions at examinations in medical degrees for external students (Blue Book, September, 1922, paragraph 4 (iii)), were amended as below; the amendment consists of the addition of the words printed in italics:

1 Candidates who have passed the B.Sc. (Pass) examination with physiology, or the B.Sc. Honours examination in physiology, or who have obtained honours at the B.Sc. examination, having taken the pass examination in physiology in respect of their subsidiary subject, will not be required to pass the physiological portion of the second examination for medical degrees, Part II, but candidates who avail themselves of this exemption will not be eligible for marks for distinction.

The Vice-Chancellor (Mr. H. J. Waring) was appointed a member of the Council of the London Day Training College and Dr. E. Graham Little a governor of the Chelsea Physic Garden.

The annual service for members of the University will be held at Westminster Abbey on Presentation Day, May 3rd, at 5 p.m., when the Dean of St. Paul's (Dr. W. R. Inge) will preach. The graduation dinner will take place on the same evening at the Grocers' Hall at 7.30 p.m.

Mr. V. Warren Low, C.B., has been appointed the representative of the Royal College of Surgeons of England on the Senate for 1923-27, and Lord Dawson of Penn and Dr. H. L. Fason have both

The annual reunion dinner of No. 55 General Hospital will be held at the Trocadero Restaurant on Saturday, May 12th, at 7 p.m. The matron and nurses are holding a reunion at 7.30 p.m. The matron and nurses are holding a reunion at 7.30 p.m. The matron and nurses are holding a reunion at 7.30 p.m.

The United Services Club, 37, Cavendish Square, at 8.06 p.m. on the same day, to which all officers are cordially invited. All those intending to be present please notify as soon as possible to Dr. H. B. Roderick, 17, Trumpington Street, Cambridge.

## NAVAL MEDICAL COMPASSIONATE FUND.

The annual meeting of the subscribers of the above fund will be held at the Medical Department of the Navy, 68, Victoria Street, on Tuesday, April 17th, at 11.30 a.m., for the purpose of electing six directors.

## HONOURS.

g the honours and awards conferred by the service rendered in the field with the 1921, to December, 1921:

C.B.E. (Military): Colonel Alfred E. C. Keeble, C.B., C.M.G., D.S.O., late R.A.M.C.

O.B.E. (Military): Captain (acting Major) Galvin A. E. Argo, M.C., R.A.M.C.; Captain (temporary Major) John Moir Mackenzie, M.C., R.A.M.C.; temporary Captain Joseph S. Pinto, I.M.S.; Captain (acting Major) Michael P. Porter, M.C., R.A.M.C.

N.B.E. (Military): Assistant Surgeon (4th class) B. A. Irvine, I.M.D.

## DEATHS IN THE SERVICES.

Inspector-General William Harris Lloyd, K.H.S., R.N. (retired), died in London on April 2nd, aged 85. He was the second son of the late William Lloyd, of Newtown, Waterford, and of Kyle, Templemore, County Tipperary, and took the L.R.C.S.I. and the M.D. St. Andrews in 1856. He entered the Navy as assistant surgeon on December 12th, 1856, attained the rank of I.G. 1893, and retired in September, 1896, with nearly forty years' service. He first served in H.M.S. *Calcutta*, in the second China war of 1857-58, receiving the medal, with clasps for Canton and Taku. While serving in the flagship *Nile* in August, 1862, he took charge of yellow fever cases from the *Hinaldo*, and in the same month was fortunate enough to get promotion to staff surgeon through a death vacancy. In 1866 he was appointed to H.M.S. *Jason*, on the North Atlantic Station; and, though he served for nearly thirty years longer, this was his last experience of ordinary medical duty at sea. In 1870 he was appointed on special duty to Haslar Hospital, in 1872 to Lisbon Hospital, and in 1876 he was posted to the Admiralty, where he remained for twelve years, receiving promotion to D.I.G. in November, 1884. During this time he represented the Admiralty at various scientific congresses, being secretary to the section of military surgery at the International Military Congress in London in 1881, and also officially attended the same Congress at Washington in 1887. He was subsequently D.I.G. of Hong-Kong Hospital from 1888 to 1890, and I.G. of Plymouth Hospital from 1892 to 1895. He was appointed honorary surgeon to the Queen in 1894, and received a Greenwich Hospital pension on February 4th, 1919. He married Phoebe, daughter of General Vincent, Bengal Army, in 1870, and had two daughters.

Captain Chakalyit Chandry Ittychariya, Indian Medical Service, died of pneumonia at Bannu, on the Punjab frontier, on February 12th. His family belonged to the State of Travancore, and in 1914, when the war began, he was a medical student in Madras University. He volunteered for service as a dresser on the Indian hospital ship *Madras*, and served in that capacity for about a year, after which he returned to his studies and graduated M.B. and B.S. Madras in 1917, taking the university gold medal. He took a temporary commission as Lieutenant in the I.M.S. in 1917, and was promoted to captain after a year's service, and in 1922 was confirmed with rank as permanent captain from August 24th, 1920. He had served in the recent great war, and, since its conclusion, in the operations on the North-West Frontier of India.

## Medical News.

THE first number of *Hygeia*, a popular magazine of health, to be issued monthly by the American Medical Association, has reached us. It is a large quarto, attractively got up, with plenty of illustrations. Among the articles in this first issue is one by Professor Walter B. Cannon of Harvard on the control of bodily processes by glands, and another by Dr. George de Schweinitz on eyestrain and its prevention; on the cover is a portrait of Pasteur, to whom Dr. Victor C. Vaughan pays a becoming tribute in the text. There are not wanting quips and cranks which may attract the frivolous to read the more serious articles, among which, in conclusion, we may mention the first of a series on "patent medicines" by Dr. Arthur J. Cramp, Director of the Bureau of Investigation of the American Medical Association. The price of *Hygeia* is 25 cents a number.

AN interesting opportunity is to be afforded to English doctors to visit a number of important Italian spas under the auspices of the Italian Government. A special tour of foreign medical men is being organized in conjunction with the Italian medical authorities, and amongst the places to be visited will be Acqui, Salsomaggiore, Lerico, Roncegno, Montecatini, Fuggi, Sirmione, San Pellegrino, and Agnano; stops will also be made at Rome and Naples. The departure from London will take place on May 29th, and the arrangements on this side are in the hands of Major W. Stormont, Italian State Railways and State Tourist Department, 12, Waterloo Place, Regent Street, London, S.W.1, from whom all details can be obtained. Special arrangements have been made for suitable Italian medical men speaking fluent English to accompany the party throughout.

THE Medical Defence Union has removed to 49, Bedford Square, W.C.1.

A POST-GRADUATE course will be held at the National Hospital for the Paralyzed and Epileptic, Queen Square, Bloomsbury, W.C.1, from May 7th to June 29th. The course will consist of clinical lectures, demonstrations, teaching in the out-patients' department, and pathological demonstrations. A course of lectures on anatomy and physiology of the nervous system will also be given if sufficient entries are received. The fee for the course, excluding anatomy and physiology, is £10 10s. and £12 12s. inclusive. If taken separately the fee for the course in anatomy and physiology will be £4 4s.

THE annual meeting of the American Medical Women's Association will be held at San Francisco on June 25th and 26th, under the presidency of Dr. Grace N. Kimball, of Poughkeepsie. The date coincides with that of the annual meeting of the American Medical Association.

A SERIES of practical demonstrations in dermatology will be given at the Hospital Saint Joseph, Paris, by Dr. Lenglet, with the collaboration of Drs. Desaux and Rabreau, and the occasional assistance of Dr. Brocq. The course will begin on May 1st. The fee is 50 francs.

DR. H. H. DALE, C.B.E., F.R.S., head of the department of biochemistry and pharmacology of the Medical Research Council, has been elected to the Athenaeum Club under Rule 11, which empowers the Committee to elect annually into the Club persons of distinguished eminence in science, literature, arts, or public service.

SIR FREDERICK MOTT, K.B.E., F.R.S., will give a course of ten lectures on "Body and Mind" in the large theatre of the medical school buildings of the University of Birmingham on Thursdays at 4 p.m., commencing on April 26th. The lectures are open to members of the medical profession, who may obtain cards of admission on application to the Dean.

AN extensive outbreak of trichinosis has recently occurred in Spain.

A MEETING of the Fever Hospital Medical Service Group of the Society of Medical Officers of Health will be held at 1, Upper Montague Street, Russell Square, W.C., on Friday, April 27th, at 3.45 p.m. Dr. W. J. J. Stewart will read a paper on "The failure of the isolation hospital to reduce the incidence of scarlet fever: a possible explanation and remedy," and Dr. M. O. Howell will report a case.

THE Prince Albert Convalescent Home, Worthing, is making a special appeal for funds, as it is in financial difficulties. This home is now maintained for the reception of convalescent women as well as men, and has accommodation for eighty-five patients. Donations or subscriptions may be sent to the Secretary, 76, Finsbury Pavement, E.C.2.

THE fifth congress of the Far Eastern Association of Tropical Medicine will be held at Singapore from September 3rd to 17th. The first congress was held at Manila in 1908, and subsequent congresses were held at Manila in 1910, at Hong-Kong in 1912, at Saigon in 1913, and at Batavia in 1921. The object of the Far Eastern Association of Tropical Medicine is to promote the science and art of tropical medicine in the Far East, and for this purpose it endeavours to unite into one compact organization the medical profession of the Far East, for the growth and diffusion of medical knowledge. The association's aim is to promote friendly international intercourse among medical practitioners, and to raise the standard of medical education. It endeavours to enlighten and direct public opinion in regard to the problems of hygiene, to form habits which may conduce to the prevention of disease among the native population, and to present to the world the results of scientific observations. Membership is open to the members of all duly constituted, regularly organized medical societies, and to all medical officials in the civil, military, naval, and other organized services of Governments, within the field of the association. According to the preliminary syllabus of the congress, its work will be carried out in four sections—namely, physiology, pathology, medicine and surgery, and hygiene. It is the wish of the scientific committee that the term "tropical medicine" should not be interpreted in its narrow sense to the exclusion of the many interesting problems in Far Eastern medicine and surgery. Dr. A. E. Horn is to be president of the congress, and the honorary secretary is Dr. J. W. Scharif, Government Health Office, Singapore, to whom correspondence should be addressed.

AT the meeting of the Medico-Legal Society to be held at 11, Chandos Street, W., on Tuesday next, at 8.30 p.m., Dr. T. W. Eden will open a discussion on the duration of pregnancy in its medico-legal aspects.

## Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

IN order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Attitology*, Westrand, London; telephone, 2630, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Medisecra*, Westrand, London; telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus*, Dublin; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate*, Edinburgh; telephone, 4361, Central).

### QUERIES AND ANSWERS.

#### BACTERIOLOGY OF SEA-WATER BATHS.

"A. G." asks for information, or references to publications, bearing on the bacteriology of sea-water swimming baths. According to his own examination, the water in a large swimming bath in the tropics shows no growth at the time it enters the bath. The water is renewed twice a week. After use by 500 people the water gives 100 organisms in 1 c.cm. and 1 *B. coli* in 10 c.cm. Our correspondent can find no published work on the subject.

#### INCOME TAX.

A, B and C were in partnership to January 1st, 1923, when A retired on terms that he was to be paid one and a half year's purchase of his share plus 6 per cent. on outstanding capital instalments.

\*\* For 1923-24 A's liability in respect of the practice is confined to the interest at 6 per cent. which he receives, and the balance of the assessment is divisible between B and C accordingly. They will, of course, pay tax on a greater amount of cash than they will receive and retain, but that is really because they are using their earnings to buy a further share in the practice—a question of saving capital, not of incurring a professional expense.

#### Car Transactions.

"D. D. R." in October, 1919, bought a four-seater 12-h.p. F. car, secondhand, for £170 (new cost was £203). In April, 1921, he bought a two-seater, 12-h.p. R. car, secondhand, for £340 (new cost in 1921 was £735). In May, 1922, he sold the F. for £24. In view of the small residual value of the F. we consider that the cost of replacement should be allowed as an expense of the year 1921. The fact that both cars were secondhand makes it difficult to separate the renewal cost from the capital improvement, and on the facts stated we do not think that "D. D. R." is likely to obtain a greater allowance than £170 - £24 = £146.

"OMEGA's" transactions have been as follows: 1908 bought second-hand Renault Coupé (£350 new) for £225; 1917 bought second-hand Adler (£350 new) for £180; 1920 bought second-hand Douglas motor cycle for £43; 1922 sold the Renault for £30—loss £195.

\*\* It is important to bear in mind that the only allowance legally due is for the cost of replacement; nothing is due for the loss on realization as such. "Omega" might—if the facts as to the use of the Renault permit—contend that the Adler was in substance purchased in replacement of the former, but the cost was incurred in 1917, which is now outside the three years' average; the Douglas similarly is only partially claimable, as it was an expense of the year 1920. Our advice is that, assuming a car will be purchased before long, to wait until then and to put in a claim that that car is in replacement of the Renault, and if the Adler is then disposed of the allowance might cover both losses, though dealt with as one for the expense incurred on the new car.

### LETTERS, NOTES, ETC.

#### WHOOPING-COUGH.

DR. THOS. CARRUTHERS (Kilbarchan, Renfrewshire) writes: Dr. Middleton's remarks on his "cure" for whooping-cough in your issue of March 10th (p. 450) occasions me to say that I have often thought of compiling a book entitled "The natural history

of disease." By the time whooping-cough is diagnosed it is about a fortnight old and it cures itself in the next month. A healthy child with its stomach kept in order never turns a hair. Until a "stopper" (as in diphtheria) is discovered that is all we can do.

#### "ORIFICALISM."

WHEN it was mentioned recently (JOURNAL, February 3rd, 1923, p. 220) in connexion with another subject, that a certain osteopath advertised himself in his craft journal as a specialist in "orifical surgery," it was not realized that this "specialty" is itself the latest development among the quack cults of America, and has already attained a notoriety there. Dr. John F. W. Mcagher of Brooklyn discussed this form of charlatanism in the *New York Medical Journal and Medical Record* of February 21st, 1923 (p. 221). His attention was first drawn to the "cult" a few years ago when caring for certain patients suffering from insanity, who had been "treated" by certain so-called "orifical surgeons." Some of these quacks (he says) have medical degrees of a kind, and they carry on their work and propaganda mainly through church clubs and women's societies. In Chicago they publish a journal of their own, and have the hardihood to call it *Constructive Surgery and Medicine*. The first idea of "orifical" or "constructive" surgery was apparently hatched some thirty years ago, and, as their organ states, "So much was said about rectal work, that the idea prevailed that orifical work meant surgery of the rectum alone, when, in fact, as we all know, it included surgery of all the lower orifices." To the true "orifical surgeon" the nose and mouth are of little account. Reference is made in their journal, nevertheless, to at least one nose and throat specialist among them: "His special work for some time has been troubles of the upper orifices and cavities, but unlike the usual nose and throat specialist, a large part of his treatment for these troubles is pelvic attention . . . the true spirit of the orificalist." The following is a case report published in the journal—the spelling is that of the author: "With fear and trembling I began dissection of the pus sack, and when I got through, I had a whole in the buttock as large as a baseball. I kept the patient in bed, and wrote the school for suggestions." One of these "surgeons" cured a case of constipation by dilating the os uteri; another cured a case of diarrhoea by treating the clitoris (vol. 7, p. 230). One writes: "I never knew where cures came from until I became a student of your course," another says, "I have been thinking orifical ever since." The osteopath and the chiropractor will have to pull up their socks.

#### A CIRCULAR OFFER.

A FEW months ago a correspondent sent us a copy of a circular handed to him by a local chemist as a curiosity. It was issued by a manufacturer of thermometers and glass apparatus in Germany and is perhaps, as our correspondent suggests, a sufficiently curious example of English as she is wrote to be worthy of reproduction:—

"Herewith I allow me to recommend you the purchase of my praiseworthy Fabricats. Principally there is to-day the artificial Men-Eyes which I offer you.

"I manufacture this artikel in the best quality, almost infrangible with imitation illusory of the naturel Eye, the best what exist and I offer you extr. mely as I.ug there is stock: [Here follows a list of prices]

"In brevity we shall have a new Price-raising-at least of 50 per cent. and thence do you not tarry a moment with your orders.

"Advanantagous Purchase—occasion for only some days. Who purchase immediately, makes very good business and gains much money by sell again. Who this occasion loses by delay makes a great mistake."

#### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 34, 35, 38, and 39 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 36 and 37.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 115.

### SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	...	...	0 9 0
Each additional line	...	...	0 1 6
Whole single column (three columns to page)	...	...	7 10 0
Half single column	...	...	3 15 0
Half page	...	...	10 0 0
Whole page	...	...	20 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not safeguarded.

Advertisements should be delivered, addressed to the Manager, 429 Strand, London, not later than the first post on Tuesday preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *post restante* letters addressed either in initials or numbers.

## An Address

ON

## THE CHRONIC ABDOMEN.\*

BY

ROBERT HUTCHISON, M.D., F.R.C.P.,

PHYSICIAN TO THE LONDON HOSPITAL.

Our surgical colleagues describe a condition which they speak of, in their clinical slang, as the "acute abdomen." There is, however, another condition more familiar to the physician which may be designated with equal propriety the "chronic abdomen," and if the one is, as we are told, a catastrophe, the other is certainly a conundrum.

The subject of the chronic abdomen is usually a woman, generally a spinster, or, if married, childless and belonging to what are commonly termed—rather ironically nowadays—the "comfortable" classes. To such a degree, moreover, do her abdominal troubles colour her life and personality that we may conveniently speak of her as an "abdominal woman." An abdominal man, on the other hand, is by comparison a rare bird, and when caught has a way of turning out to be a Jew—or a doctor.

## SYMPTOMS.

The symptoms of the chronic abdomen are many, various, and ever-renewed. Some of them refer directly to the abdominal organs, others are of a more remote and general character; but, whatever they are, they are always described with great prolixity and in minute detail. Amongst those most commonly complained of are abdominal aches and pains of various sorts and in various places, but especially in the right iliac fossa. Instead of actual pain the patient may speak of a "raw feeling inside," or of "an indescribable sensation in the stomach," or of a "dragging." Constipation of greater or less degree almost always figures prominently in the list of symptoms, and flatulence is also frequent. Amongst the commoner remote symptoms one finds a feeling of general weakness or "exhaustion" (especially after an action of the bowels), "mental and physical torpor," "inability to think," "a poisoned feeling," and "neuralgic pains all over." Head-aches and insomnia are also very frequent, and a great many patients complain of undue susceptibility to cold and of a constant catarrh in the throat.

## EVOLUTION OF THE CHRONIC ABDOMEN.

If one inquires of a patient with a fully developed chronic abdomen how her lamentable state has been arrived at it will be found that the process of evolution is fairly constant. These sufferers are very fond of presenting anyone whom they may consult with a full record of their previous medical history and experiences, and the following are a few such records as supplied by the patients in their own words. They may be taken as typical.

## CASE I.

Mrs. L., aged 47, gave the following record of her various illnesses and their treatment:

Bad fall at 2 years of age. Rheumatic fever at 13. Always bad digestion and overloaded bowel. Married at 21. After birth of first child, ulceration of rectum. Uterus never strong.

1900: Two operations for fistulae and abscesses—tumour (fibroid) discovered in uterus. Always feeling ill from auto-intoxication (enemas curing this) and rheumatism in knees (cured by inoculation).

1901: Cocaine poisoning.

1902-1909: Cures at Aix, Strathpeffer, Bath, Carlsbad, and quinine.

1910: Operation for "chronic appendicitis" and six tumours in uterus. Intestines never felt in place or strong after this. Same as: Pyorrhoea; inoculations.

1911: Cancer of the breast—operation.

1912: Went to Bath for "nerves." Several teeth extracted.

1913 (March): Played golf for first time and thought intestines were dragged down. Jumped out of train and ran hard (quite fast); inside never comfortable since then; pains in bladder; craves!

May: Small fibroid discovered. Uterus half size too large. Inflammation of bladder, uterus, and general tissue; nerves terribly bad; douches, etc., in a home.

August: Contrexville (concentrated urine and excess of uric acid). Contraction of intestines; pains in kidneys; always pain in bladder—diarrhoea. Nerves—nerves. Constipation. Passed large quantities of sand.

\* Delivered before the Clinical Society of Manchester, March 8th, 1923.

Now  
pressed  
Always

Rectum feels as if  
nerves better.  
ience.

## CASE II.

Miss M., aged 48. Seen in 1913, complaining of constant acidity, flatulence, vomiting of green fluid, etc.

## History.

At 5 years of age had severe jaundice and stoppage of bowels; always constipated.

At 20: Influenza and bronchitis with prolonged fever; this left "stomach trouble" which persisted.

At 32: "Dilatation of stomach," and was in bed three months.

At 33: Uterus curetted; indigestion better for a time.

At 35: Complete hysterectomy and appendectomy. Digestion much better for over a year.

At 38: Digestion bad again—stomach lavage—much benefit for a month.

At 40: Cholecystitis and "ulcer of stomach."

At 42: Rest. cure in hospital. Stomach massage. "Much benefit."

At 48: Exploratory operation. Stomach and colon fixed with catgut sutures.

One and a half years later she wrote:

"... Am glad to say I never now (since operation) get those turns of agonizing pain in region of gall bladder which used to suggest gall stones; but there is always a sore burning spot there, sometimes pretty bad, with often slight cutting sort of pains (but only slight), and it goes when the apparent cause of corrosion of wind or food has moved.

"My old 'sore spot' (on left side under lowest rib near middle) has come back, and I am in constant distress from the burning, gnawing sensation right across below waist line. Also all over back and under shoulder blades.

"I have really been little more than an invalid for months, finding it most difficult to continue my teaching, having scarcely strength to speak. It seems to be the continued acidity and tremendous flatulence, and the sensation of weakness (I suppose) is because the heart is being almost continually choked with dilatation of stomach. About a month ago it was 'murmuring'—I do not know if it is still doing so. It feels as if a heavy weight is pressing the heart and sometimes there is neuralgic pain in its region and in left arm and I can't breathe easily. But doctor says it is not due to heart itself; that appears strong, but the effect of faintness and exhaustion is very bad sometimes, though occasionally I am able to forget it for a day or more. Of course it hinders sleep when bad. Am glad to say the fearful violent jumping—which was such a trial all the time in hospital and for eighteen months after—is almost gone and the rheumatism is better and the sudden turns of sickness less frequent. I rest all I can and do most of my work at home, so that if I find a heart turn coming on I can drop lesson and let off the tremendous flatulence in violent noisy 'spasms.' If I check them I become helpless.

"I have just started to try and take olive oil (a large teaspoon a day) and since doing so have felt easier and had no spasms, but this may be chance, but shall persevere. Bowels need 20 or 25 senna pods now to move them."

## CASE III.

Miss J., aged 29. Seen in January, 1908. She had always been delicate, especially as regards digestion.

## History.

June, 1889: Peritonitis. Abscess came away into rectum.

January, 1897: Entered on office work—health became worse.

October, 1898: Influenza (high temperature) followed by jaundice. Since have always had constipation.

1899-1900: Indigestion becoming worse.

June, 1900: Operation—two abscesses in glands on right side of abdomen, one of which had broken; considerable amount of matter; slight perforation. Since digestion has always been very troublesome.

1902-4: Digestion becoming worse and worse.

October, 1903: Six weeks' "rest cure" in bed with massage; no permanent improvement.

February to April, 1904: Being in Switzerland, six weeks' treatment in hospital there; no improvement.

May and June, 1904: Seven weeks' treatment in Zurich: no improvement.

October, 1904: Operation (gastro-enterostomy)—pylorus said to be fixed by adhesions. Digestion has since been very indifferent.

Since last date, pain and distension at intervals of from two to four weeks, lasting from periods varying from one to six or more weeks.

## CASE IV.

Mrs. T., aged 41. Seen 1917, complaining of pain in epigastrium and left hypochondrium, flatulence and acidity.

In 1907 right kidney fixed.

In 1908 appendix removed.

In 1909 operation for tubal pregnancy.

In 1913 other tube and ovary removed—since then indigestion.

In 1915 rest cure.

In 1917 exploratory operation—nothing found except that the omentum was adherent to the scar in the right iliac region.

Remained well for four months, when epigastric pain returned acutely with the symptoms described above.

## CASE V.

Mrs. H., aged 53. Seen 1915 for obstinate constipation; "neuritis" in various parts of the body, swelling and tenderness of the breasts, etc.

## History.

1886: Haemorrhoids removed.

1887: Curetting.

1888: Five cauterizations of uterus.

1898: Haemorrhoids removed again, and bowel stretched as far as they could reach. This resulted in loss of power in lower bowel and aggravated the trouble.

1905: Uterus and large fibroma removed and one ovary, in which was a cyst. The surgeon thought the fibroid growth behind the uterus was strangling the intestine, but the latter was not improved after the operation.

1910: Bismuth test and exploratory operation. Five places where tight bands had grown round the intestines—worst place left side of the colon three times round and a very thick string. It left a deformed colon, but as the place seemed elastic they did not cut it out.

This trouble continues, and since May last I have had mucous colitis. The slightest solid undigested matter causes stoppage, and there is constant delay. I only make matters go at all by daily injections and aperients. The poisoning is resulting in nerve pain and swellings in different parts of my body.

It will be observed that the road to chronic abdominalism is paved with operations. The usual sequence seems to be this: the patient begins by complaining of pain or discomfort in the right iliac fossa, for the relief of which the appendix is removed. For a few months she is better. (It is characteristic of the disease that almost any new treatment, and especially any operation, produces benefit for a time.) Soon, however, her symptoms return. This is put down to "adhesions," and another operation is performed to remedy these, with the same result as the first. Warming to his work, the surgeon undertakes bolder and yet bolder proceedings; a complete hysterectomy is probably carried out or some short-circuiting device, or the colon is fixed, or even partially removed, but still the patient is not cured of the pains, whilst the state of the nervous system has steadily worsened.

It is interesting to note at this point how medical history repeats itself. Writing in the eighties of last century on the abuse of gynaecological operations in the treatment of visceral neurosis, Sir Clifford Allbutt said of the abdominal woman of that day:

"She is entangled in the net of the gynaecologist, who finds her uterus, like her nose, is a little on one side, or again, like that organ, is running a little, or it is as flabby as her biceps, so that the unhappy viscus is impaled upon a stem, or perched upon a prop, or is painted with carbolic acid every week in the year except during the long vacation when the gynaecologist is grouse-shooting or salmon-catching, or leading the fashion in the Upper Engadine. Her mind, thus fastened to a more or less nasty mystery, becomes new-y apprehensive and physically intro-spective, and the morbid chains are riveted more strongly than ever. Arraign the uterus and you fix in the woman the arrow of hypochondria, it may be for life."—On Visceral Neurosis, Goulstonian Lectures, 1884.

Substitute "surgeon" for "gynaecologist" and "appendix" for "uterus" and the parallel is complete. At that time the uterine organs were the scapegoat of the abdomen; now it is the appendix—if, indeed, it is not already the teeth or the tonsils.

Meanwhile, and between the more dramatic entries and exits of the surgeon, the physician has not been idle. The patient has been thoroughly "investigated"—possibly at a "team-work" clinic; she has certainly been provided with an x-ray picture-book of her entire alimentary canal; her teeth have been extracted and her tonsils excised; her motions have been analysed by a biochemist and her mind by a psycho-analyst; she has had several rest cures; she has been given prolonged courses of vaccines, of intramuscular tonic injections, of intestinal antiseptics, and of endocrines; she has been fed on sour milk or minced beef or raw vegetables; she has experienced various forms of massage, has been subjected to the latest kinds of electrical current, and has had her colon repeatedly washed out at Plombières or Harrogate.

In a word, she has run the whole gamut of "modern" therapy, has submitted to every "stunt" and conformed to every fad—but is none the better. And just as she can only escape the attentions of the surgeon when—as Sir Clifford Allbutt said of the gynaecologist—he is "grouse-shooting or salmon-catching or leading the fashion in the Upper Engadine," so she is only at peace from the physician when the latter is recruiting his exhausted energies by a short holiday at an inexpensive seaside resort.

## PHYSICAL AND MENTAL STATE.

On examination of a fully developed case of the chronic abdomen one will find that it has both a physical and a mental aspect, and that the latter is often the more important of the two.

Physically the patient is undernourished and sallow. To use an abominable term current at the moment, she looks "toxic." The abdomen is of visceroptotic shape and the surface criss-crossed with scars, the signs-manual of the surgeons who at one time or another have conducted exploring expeditions into the interior. The stomach is dropped and splashy and the right kidney more or less movable; there is tenderness at various points over the colon. Constipation will probably be obstinate, and the motions usually show the presence of mucus or even membranes.

The mental side of the case is more difficult to analyse. There is notable, in the first place, a general discontent, "disgruntlement," and peevishness, added to which is an intense egotism which leads the patient to regard herself and her symptoms as of the utmost importance. In a play called *The Mollusc*, which appeared some years ago, this aspect of the abdominal woman was admirably depicted, but I noticed that all my patients of this type who went to see it simply remarked, "How absolutely like Mrs. So-and-so!" None of them recognized the Mollusc as herself. Needless to say, the patient is also intensely introspective and hypochondriacal. She studies and catalogues her symptoms with minute care, and is expert in a knowledge of the action of drugs and a connoisseur of doctors and "specialists."

"She has seen heaps of specialists," a doctor wrote to me of a typical example, "and no doubt will continue to do so. You will be amused and interested to hear that she promptly went off to another specialist after seeing you."

The operation habit has often a strong hold on her. Added to all this, and most trying of all, is an intense craving for sympathy which must be satisfied at all costs, and it is noteworthy that there is usually someone in her entourage who is always ready to supply the need. Sometimes an unmarried daughter is the victim; sometimes it is an over-devoted husband. One should not, however, commiserate him too much, for, like the husband in *Bunty*, he is often a "weelin' victim" and always ready to kiss his chains.

Her incessant demand for sympathy and understanding makes the abdominal woman a veritable vampire, sucking the vitality of all who come near her. Half an hour with her reduces her doctor to the consistence of "a piece of chewed string," and is more exhausting to him than all the rest of his day's visits put together, for she is always discontented, covering fresh symptoms, will not admit any improvement in her condition, and has an objection to everything that is proposed. Crabbe must have had her in mind when he wrote of the patients—

"Who with sad prayers the weary doctor teases  
To name the nameless ever new disease."

"My *bête noire*, Miss —, is coming to see you soon," a medical friend feelingly wrote to me of an extreme example. Fortunately, however, she never sticks to one doctor long, but is always rushing off after fresh advice, and her nurses can always be changed at short intervals; if they were not, they would go mad.

## THE NATURE OF CHRONIC ABDOMINALISM.

When one comes, then, to analyse a case of the chronic abdomen, it is found to consist on the physical side of a state of visceroptosis along, usually, with a greater or less degree of mucous membranous colitis, and, on the mental side, of that morbid psychological state which was sketched above. But now comes the conundrum. How can the physical basis produce the multifarious symptoms of which the patient complains, and what is its relation to the mental side of the picture?

It is common knowledge, of course, that many women have pronounced visceroptosis without being much affected by it either physically or mentally. Why, then, do these particular patients appear to suffer so much? Again, what part does mucous membranous colitis play? It is true that one rarely sees a sufferer from that disease who does not exhibit in greater or less degree the mental characteristics of chronic abdominalism, but what is the relation of the one to the other? Does the colitis affect the mind, or is it the other way round? I need not remind you, of course, that there is a school of thought which would attribute all the remote

ical symptoms of chronic abdominalism, and presumably mental symptoms also, to "auto-intoxication." This line has been so much discussed in recent years that I do not propose to weary you with a further consideration of it; although there may be an element of self-poisoning in some of these cases, I feel bound to express the opinion that it does not account for all the symptoms. Nor have I any theory to offer. There remains, when all is said and a good deal of mystery about the chronic abdomen, and I do further study—especially, perhaps, from the psychological side and from the standpoint of the relation of the digestive nervous system to the emotions.

#### TREATMENT.

the treatment of the chronic abdomen the most important thing is to catch the patient early. If she has once got on to the slippery slope which leads to successive relapses she is undone. A timely "fattening cure," followed by the provision of an efficient abdominal support, regulation of the bowels by the mildest laxative, supplemented if necessary by simple enemata, an abundant but unirritating diet, soothing of the nervous system by bromides—these are the physical measures. On the mental side the patient should be encouraged to take up some definite occupation which will provide her with an interest outside herself.

In an incipient case such means may suffice, but if one has to do with a confirmed example of the disorder one's task is much more difficult. At the outset the question of operation is sure to arise. The patient will probably have already had her appendix removed at least, and if any further operation is decided upon it is best, I believe, to make it of a purely exploratory character. The incision should be large enough to permit of a thorough investigation of all the viscera—for even the chronic abdomen may be the seat of organic disease—any bands or kinks may be dealt with, but short-circuits are to be avoided at all costs, and organs should not be removed unless they are demonstrably diseased. Whether fixation of the colon is worth while I do not know, as I have not seen a sufficient number of cases in which at least two years have elapsed since the operation. Immediate benefit is no criterion of permanent relief, for, as I have already pointed out, these patients are always improved for a time by a new treatment. Colectomy of any degree is a grave proceeding not to be undertaken lightly. In any case a thorough exploration may at least satisfy the patient's mind as to the absence of serious organic disease, and so pave the way for a healthier mental attitude in future.

Apart from operation, the physical treatment will proceed on the same lines as in an early case, but success is much more difficult to attain.

There remains the mental side to be dealt with. What is to be desired here is something which will dislocate the patient's mind from its perpetual revolution round her umbilicus and set it open to wider horizons. The war cured some and loss of fortune and bereavement have cured others; but these are drastic remedies which it is not within our power to prescribe. Suffragetteism undoubtedly was the salvation of some abdominal women, but the suffragettes are now experiencing the tragedy of fulfilled ambition, and probably many of them have relapsed. Marriage, and the advent of a child—even an adopted one—are often potent remedies, and the fancy religions—Christian Science, Theosophy, Spiritualism, and so forth—may be ways of escape. One of my patients, an ex-nurse (and ex-nurses furnish the most malignant types of the chronic abdomen), once consulted a palmist, who after looking at her hand said, "If I were your husband I would take a stick to you!" The advice was sound, and might often, perhaps, be effective. Whether the methods of M. Coué will help these patients remains to be seen. The difficulty is that many of them, despite their protestations to the contrary, really lack the will to be well, and their daily litany is: "Day by day, and in every way, I get worse and worse."

I confess, therefore, to some feeling of despair as regards the treatment of the more advanced cases of the chronic abdomen, and on the whole I am inclined to think that the less one has to do with them the better both for one's peace of mind and one's professional reputation. Yet, unfortunately, these cases are likely to increase in the future, for as civilization gets more complex, as fewer women in the upper classes marry, or, being married, have fewer and fewer children, all the factors which favour the development of chronic abdominalism will be more intense. It is a bleak prospect.

## MAN'S POSTURE: ITS EVOLUTION AND DISORDERS.

GIVEN AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND

BY

PROFESSOR SIR ARTHUR KEITH, F.R.C.S., F.R.S.,  
CONSERVATOR OF THE MUSEUM.

[Abstracts.]

### LECTURE VI.—THE EVOLUTION OF THE HUMAN FOOT.

WHEN dealing with the evolutionary history of the spine, thorax, abdomen, and pelvic floor we found that the human condition was the last of a series of steps which are seen to begin in the small orthograde ape, the gibbon. The missing evolutionary stages are not those which bridge the hiatus between the great anthropoids and man, but those which fill the gap between the orthograde gibbon and the older pronograde condition seen in monkeys. When, however, we came to consider the structure of man's groin and, to lesser extent, his pelvic floor, we found that the evolutionary gap was seen to lie between the human and the anthropoid stages. This is the case as regards all parts of man's lower extremities; more particularly it is true of his foot. Even in the gorilla, the anthropoid which shows the nearest approach to man in the use of its lower extremities for support of the body, the great toe is free and used as a grasping thumb.

The central evolutionary problem of the human foot is: How did the thumb-like great toe lose its independent nature and become merged in the metatarsal series? By what process did the free mobile great toe of the prehensile primate foot come to form the principal part of the rigid plantar arch of man? The transformation is all the more remarkable when we remember that a prehensile hallux was present at the first dawn of the primate type of animal, and has retained this form throughout the long history of the order, with the exception of that aberrant being, man.\* In him the hallux has reverted to a primitive position in the metatarsal series.

#### *Has the Foot of Man been Evolved from one which was Prehensile?*

At the very outset this question must be asked and answered: What evidence is there that the human foot has passed through a prehensile stage? The human foot has the same structural composition as the ape's foot—the same bones, the same muscles, the same ligaments; it is only their arrangement and form that have become modified in the human foot. If in the higher primates we compare bone after bone, muscle after muscle, ligament after ligament, we find in every case a series which leads from the type seen in the pure prehensile foot of monkeys to the stage reached in the human foot. Take, for example, the three contrahentes muscles to be seen in the sole of the monkey's foot; they serve to approximate the heads of the metatarsal bones. In the sole of the human foot they are represented by mere fibrous strands; the story of their degeneration can be read in the feet of the orthograde apes. They are still present in the gibbon; they are in the retrograde stage in the chimpanzee, they are almost as much reduced in the foot of the orang and gorilla as in that of man. The interosseous muscles of the monkey's foot do not lie between the metatarsal bones, as in the human foot, but on their deep or plantar aspect. In the gorilla and orang they are set as in man; in the gibbon they occupy an intermediate position. Yet as the interosseous muscles appear in the foot of the human embryo they are set and arranged as in pronograde apes. In the course of development they take up their intermetatarsal position. We shall cite, when dealing with the structures which maintain the arch of the human foot, other evolutionary links which make us certain that the human foot is but the culminating stage in a series foreshadowed by anthropoid feet.

#### *Flexion Lines of the Sole.*

No more convincing evidence of the prehensile history of the human foot can be cited than the flexion lines to be seen

\* See Professor Wood Jones's *Arboreal Man*, 1916.

on the sole of the baby's foot. Line for line they agree in their relative position and form to the flexion folds to be seen on the sole of the gorilla's foot. The sole of the newly born child has the inverted anthropoid position—an adaptation for grasping and climbing. The articular face on the internal cuneiform, on which the base of the hallux moves, is set obliquely in the foot of the human infant, thus recalling the original prehensile nature of the great toe. The astragalus of a baby has, in its general shape, and in the form of its articular surfaces, many points in common with the astragalus of the great anthropoids. Seeing how different is the use to which the great toe is put in man and apes it is wonderful that the muscles which serve the one can be made to answer the needs of the other. Only one hallucial muscle has been radically transformed in man—the short flexor of the great toe has had a second belly added to it. The other muscles have undergone a mere change in size and attachment.

#### *The Shaping of the Human Foot.*

When we take all these points into consideration there can be no hesitation in believing that the human foot has been evolved from one which was prehensile, and that stages leading on to the human form are to be seen in the feet of anthropoid apes. And yet in the development of the foot of the human embryo a prehensile stage—an ape-like foot—is at no time to be seen. If it were true that the human embryo, at every point of its development, recalled, or passed through, an ancestral phase, then we should expect to see a simian stage in the developing human foot. But the law of recapitulation is only partly true; development is a double process—it is recapitulatory, but it is also anticipatory. We see the two processes proceeding side by side and masking each other; atavistic features appear in the developing foot side by side with the new ones. The human foot was never shaped by any effort made by the growing or grown anthropoid ape, as Lamarck supposed, but arose for the first time in the embryonic foot—under the influence of the growth mechanism which controls the development of that organ. Hence it is that, up to a stage corresponding to the point reached by a human embryo at the end of the second month of development, the foot and toes of man and ape are much alike—the toes radiate forwards from the tarsus and all are united in a common web. At this stage the arrangement of digits is really that seen in five-toed mammals; it is an ancient form. Even at this stage the great toe of man is predominant in thickness although not in length. Then at the stage where the webbing disappears from the digits of the foetal ape and the great toe assumes its separate status, the foot of man goes on retaining the great toe in the primitive adducted embryonic position. The adducted position of man's great toe came about by arresting development at an early point of digital differentiation. It will be found to be true of nearly all the structural features which are distinctive of man's body that they make their first appearance in the embryonic or foetal stages of apes; subsequently they blossom to their full in man's body. Such foetal structures are not, as so often thought, recapitulations of ancestral phases; they are new evolutionary creations.

#### *Functions of the Foot.*

Such evolutionary studies as I am now laying before you are of interest and of use to medical men only if they throw light on how the human foot came by its functions as well as by its form. How did the supple prehensile simian foot become modified to serve as a lever—the "stepping-off" lever—so necessary for man's progression? In cases of "flat-foot" the lever becomes broken, and we know well how crippling this disaster can be. If we examine the foot of a pronograde monkey, or even of the orthograde gibbon, we see that it is in reality a Y-shaped prehensile organ. The stalk of the Y is represented by a short tarsus; the limbs of the Y represent the opposed digital and hallucial elements of the grasping organ. The hallucial limb is directly articulated on the tarsus, for its metacarpal bone serves as a phalanx in the grasping foot. In the digital limb of the grasping foot the four metatarsal bones are fixed with some degree of rigidity to the tarsus; the mobile toes articulate on the metatarsal segment of the sole. Thus, taking no notice of the great toe in the meantime, we see that the primate foot is made up of three functional segments—tarsal, metatarsal, and digital—each serving its own peculiar use in the prehensile foot. Now if we note what has happened to these three elements in the feet of the higher primates, as set out in the following table, we see that,

*Table Showing the Proportion formed by each Element of the Foot in Man and Allied Primates.*

	Proportion of Tarsus.	Proportion of Metatarsus.	Proportion of Phalanx.
<i>Semnopithecus</i> (monkey)	28 per cent.	33 per cent.	39 per cent.
Gibbon ... ..	28 ..	30 ..	42 ..
Orang ... ..	27 ..	33 ..	40 ..
Chimpanzee ... ..	32 ..	33 ..	35 ..
Gorilla ... ..	39 ..	23 ..	33 ..
Human infant ... ..	46 ..	31 ..	23 ..
Man (adult) ... ..	52 ..	30 ..	18 ..

in all, the proportionate length of the metatarsal element remains nearly the same; on the other hand, as the digital element shortens, the tarsal element increases in length and strength. If we measure the length of a monkey's foot, from the heel to the tip of the longest toe—which is the middle digit in old-world monkeys—we note that while the tarsal element makes up only about 28 per cent. of the total length the digital or phalangeal element makes up 39 or 40 per cent. At the other end of the series we find the foot of man, in whom the tarsal element makes up more than 50 per cent. of the length while the digital element provides less than 20 per cent. of the length. Between these extremes lie a series of intermediate forms. In the proportion of the three elements the foot of the gibbon differs but slightly from those of the monkey; the evolution of the orthograde posture did not affect the proportion of the elements in the foot. With the evolution of the heavy bodies of great anthropoids the supporting or tarsal element underwent a great relative growth. This is not so evident in the orang because the foot has become specialized in a way opposite to that which occurred in the human stock; in the orang the hallucial element of the foot atrophied while the digital element underwent a great development. In man the hallucial element became predominant, the digital greatly reduced. Were it not for the form represented by the foot of the gorilla there would be a very decided break in the series leading from the anthropoid to the human foot. The proportions seen in the infant's foot helps to bridge the gap between the gorilline and adult human types. Thus we see that in shaping the feet of the higher primates Nature has gained her ends by increasing the tarsal or supporting element and diminishing the digital or grasping element. The human foot represents the climax of an evolutionary movement which began long ago in an anthropoid ancestry.

#### *History of the Great Toe.*

Turning now to trace the evolutionary history of the great toe or hallucial element, we note that in pronograde monkeys the length of the great toe is about 55 per cent. of the length of the middle or longest toe. In this measurement is included the length of the metatarsal bones as well as of the phalanges. Measured by the same standard, the great toe of the gibbon is 67 per cent., that of the gorilla and of the chimpanzee is 68 per cent., while in man the great toe is usually equal to or greater than the length of either the second or third toe. The great toe of man has reached the 100 per cent. standard, but it must be remembered that this result has been attained as much by the reduction of the phalangeal elements of the four outer toes as by a real growth on the part of the constituent bones of the hallux. Nevertheless, the peculiar features of the human foot have been worked out by an overgrowth of the hallucial element as well as by the incorporation of this element in the metacarpal series.

#### *Evolution of the Plantar Arch.*

We come now to the most difficult part of our inquiry: How did man come by that peculiar feature of his foot—the longitudinal plantar arch? When the arch collapses, as in cases of flat-foot, the chief breakdown occurs at the mid-tarsal joint—particularly between the head of the astragalus and the rest of the tarsus. Now in pronograde monkeys the mid-tarsal is a flexible joint; when a monkey is "stepping off" from a branch it will be noticed that, while the heel is being raised, the hallucial and digital limbs of the foot still maintain their grasp; the heel is raised at the mid-tarsal joint. Although the orthograde gibbon retains the flexibility

of foot seen in pronograde apes, one no longer sees a pure flexion movement taking place at the mid-tarsal joint. In the great anthropoids the tarsus has gained in strength and rigidity, yet movements of inversion and eversion still take place at the mid-tarsal joint with the greatest freedom. The tarsus of the great anthropoid serves the purpose of a lever, but there is no plantar arch. Even in the gorilla, the least arboreal of the great anthropoids, there is no arch; the sole of the foot is applied flatly to the branch which supports the weight of the animal. All the muscles of the sole and digits are concerned in grasping. The foot thus fixed to the branch becomes a base from which the muscles of the leg act in supporting and balancing the weight of the animal. Every muscle which has a tendon ending in the foot becomes a mover and balancer of the leg. It is only when we note the manner in which the chimpanzee, and particularly the gorilla, applies its feet when walking on the ground that we realize the possibility of the grasping anthropoid foot becoming converted through a series of serviceable intermediate stages into a supporting plantigrade one, such as we see in man. We obtain further confirmation of the possibility by observing the manner in which an infant learns to use its feet in walking. The anthropoid traits, very recognizable in the feet of Neanderthal man, lend countenance to the same line of reasoning. The gorilla, when on the ground, rests the weight of its body on the outer margin of the inverted foot. The foot is maintained in the inverted position by the anterior and posterior tibial muscles. The inverted margin of the tarsus is the beginning of a plantar arch; it is maintained in position by the action of the tibial muscles, which now assume a postural function. They have become postural muscles and work against their opponents—the long and short peroneal muscles—which also have now assumed a postural rôle. Between the invertors and evertors the foot is steadied, and the in-turned position of the sole maintained. The feet, being no longer grasping structures, become props on which the body has to be balanced.

In the application of the sole of the human foot to the ground in walking we can recognize three phases: first the heel comes in contact; then the weight of the body is brought to rest on the outer margin of the foot, and on the transverse pad of the sole; lastly, in stepping off, the weight of the body is thrown on the front part of the foot, particularly on the phalangeal elements of the great toe. In the gorilla there is the same sequence of events: the heel is applied first; the weight of the body comes to rest on the outer margin of the inverted foot; lastly, in stepping off, the toes, particularly the abducted great toe, are applied and used as a fulcrum. Now the inversion of the foot has raised the inner margin of the tarsus on which the great toe of the gorilla is hinged. We have only to suppose the incorporation of the metatarsal element of the great toe as a member of the metatarsal series of an inverted anthropoid foot to obtain the arrangement of parts which go to make up the longitudinal plantar arch of the human foot. The incorporation of the first metatarsal takes place, as already mentioned, in early embryonic life. The evolution of the plantar arch was dependent on an assumption by the tibial muscles of a postural supporting action.

We have spoken as if the simian great toe had been adducted to the other metatarsals during the evolution of the human plantigrade foot. There is evidence that the approximation was brought about as much by the bending inwards of the four outer metatarsals as by a bending outwards of the great toe. In the anthropoid foot the outer metatarsals continue the axis of the os calcis; the great toe continues in the main axis of the astragalus. In the human foot the great toe still maintains the direction of the astragalus but the outer metatarsals are turned inwards from the axis of the os calcis.

From these facts we infer that in the evolution of the human foot all the elements of the great toe became hypertrophied and that the hallux soon became functionally important in the act of stepping off. The four outer toes underwent a retrogression and their metatarsals were approximated to the hallux as much as the hallux to them. Much depended on the hypertrophy of all the elements of the great toe and on the retrogression of the phalangeal elements of the four outer digits. The growth of the tarsus, particularly of the heel, and the retrogression of the outer toes have already given a semi-humanoid character to the foot of the gorilla.

### *Evolution of the Supporting Structures of the Sole of the Foot.*

The tendon of the plantaris muscle plies over a synovial groove on the heel of pronograde apes and ends in the plantar fascia. In the orthograde gibbon the heel has grown through the tendon; the plantar aponeurosis, being cut off, now forms a supporting structure for the sole. This is the case in all orthograde primates; in all of them the plantaris has become a vestigial muscle; it is more frequently present in the calf of man than in the leg of any kind of anthropoid, which probably is due to the overgrowth which has overtaken all the muscles of man's calf.

In the cutting off of the plantar aponeurosis and its fixation to the heel we see the first step in the evolution of the set of structures which help to support the sole of the foot. Another evolutionary change is seen in the short flexor muscles of the toes. In man all four bellies of this muscle rise from the heel and end in the toes; they serve to support the arch. In the prehensile, flexible foot of a monkey only the belly to the second toe arises from the heel; the other three have their origin from the movable tendons of the long flexors of the toes. In the great anthropoids the belly of the muscle to the third toe has also shifted to the heel; in a certain proportion of orangs and gorillas the muscle to the fourth toe has also gained an attachment to the heel; in man only has the belly to the fifth toe been shifted. Here we see further adaptations for plantar support. The action of the short flexor muscles has been changed by a migration of their point of origin.

Further changes of the same kind are seen in the strengthening of the quadratus plantae of the human foot; in only man is found the inner head of this muscle. Mention has already been made of the migration of the interosseous muscles to a position between the metatarsal bones. Such a position gives them power to brace together the metatarsal elements of the foot. In the human foot the internal ligaments of the tarsus and of the tibia and tarsus have been strengthened.

### *Flat-foot.*

The evolution of the human from a grasping foot was necessarily attended by the creation of a neuro-muscular mechanism for maintaining the plantar arch. The muscles which became adapted for this new function were those used for inverting, everting, and fixing the tarsal elements of the prehensile simian foot. Slight modifications in the tendinous insertions of the anterior and posterior tibial muscles made them efficient supporters of the instep; the evertors, the long and short peroneal, required no alteration to serve their new purpose. A new evertor—the peroneus tertius—came into being in the human foot; it arose by the separation of the outer part of the long extensor of the toes. Every stage of its evolution is represented in the variations which occur profusely in the leg of modern man. The grasping muscles of the sole became converted into postural supporters of the arch. Flat-foot occurs when the postural function of the supporting muscles breaks down. Why the postural muscular mechanisms of the human body are so apt to become disordered we do not know. When that of the plantar arch breaks down the human foot reverts to a condition comparable to that seen in the grasping arboreal foot of anthropoids. The mid-tarsal joint becomes again freely movable; the metatarsal elements of the foot become turned outwards or everted—just as they are in the foot of an anthropoid when seizing a branch. Flat-foot is a reversion also in this sense: it results from the loss of a recently evolved function—one which man has attained late in his history.

### *Hallux Valgus.*

Of all the primates, only man suffers from disorder and disease of the condylar joint of the great toe—the joint between the head of the first metatarsal and the base of the proximal phalanx. A knowledge of man's history helps us to understand why he has become the subject of this crippling deformity. Even in the gorilla, the most terrestrial of man's next-of-kin, the great toe is constituted so as to serve as a grasping thumb. Its metatarsal bone is freely movable, having the tendons of two muscles inserted to its base—the tibialis anticus and peroneus longus. Three short but stout muscles—the abductor, flexor brevis, and adductor obliquus—bend the proximal phalanx and thus assist in securing the arboreal foot grasp. The terminal phalanx is bent by the long flexor. Now in man all of these muscles have been retained, but their actions have been changed. The metatarsal bone has become stabilized

as part of the arched lever of the foot; the two muscles attached to its base—the peroneus longus and tibialis anticus—have become postural in function, assisting in maintaining the arch of the foot. The two terminal phalanges, in place of being the movable parts of a grasping digit, have become the chief part of the fulcrum or base from which the human foot steps off; with each step the weight and force of the body falls on this joint of the great toe. Hence, with the evolution of the human foot the muscles which act on the phalanges, particularly the short muscles acting on the basal phalanx, had to take on a new rôle—they had to adjust and maintain the position of the hallucial phalanges at every phase of the “step off.” Hallux valgus results from a breakdown of the neuro-muscular machinery which guards the condylar joint of the great toe. No doubt ill fitting boots contribute to this breakdown, but when it is remembered that the action of muscles which cross a joint are largely regulated by stimuli which arise within a joint, we see good reason for suspecting that the initial factor in the cause of hallux valgus arises within the joint itself. We do know that people of certain constitutions are particularly prone to disorders in the ball joint of the great toe.

#### *The Normal Position of the Great Toe.*

One last point as regards the “normal” position which the human great toe should hold to the rest of the foot. From a study of the footprints of native and unshod races, and also of English infants and children, I realize that a healthy and unblemished great toe may vary in position between two extremes. If on a footprint a line be drawn along the inner border so as to touch the impresses of the margin of the heel and of the ball of the great toe, what may be called an “inner directional” line is obtained. If a similar line be drawn along the outer border of the imprint—from heel to the outer margin of the foot-pad—an “outer directional line” is obtained. In healthy normal children and natives the great toe may be parallel to either outer or inner line, or may lie at any angle between these lines. The inner direction is the more simian, but which is the more liable to become the site of hallux valgus I have no evidence.

## A CASE OF HYPERPIESIA.

REPORTED BY

D. C. L. VEY, M.C., B.A., M.B. CANTAB., M.R.C.S., L.R.C.P.,  
HOUSE-PHYSICIAN, UNIVERSITY COLLEGE HOSPITAL.

With Commentary by

SIR CLIFFORD ALLBUTT.

FREQUENT as this malady is amongst the well-to-do classes of life, it is—so far as my experience goes (C. A.)—scarce in hospital practice. Moreover, by the duration of the malady, and its consistency for some long period with good health, the story is often broken or incomplete. When the patient has to seek advice, he may pass from one physician to another; in private practice, for various reasons, necropsies are rarely obtained, and when obtained may be very perfunctory. Consequently, until Dr. Batty Shaw made, in his recent book, a solid and valuable contribution to its pathology, our stock of fully observed instances of hyperpiesia was very scanty.

A patient, a man aged about 60, died during last Lent term in the Addenbrooke's Hospital with arterio-sclerosis, a very large heart, and a systolic pressure of 210 mm. But little was known of his history, and before death there had not been much time for an adequate series of biochemical and other observations. The necropsy was made by Dr. J. F. Gaskell, who reported that the kidneys (of which I made a naked-eye inspection) were quite normal. Death was by cardiac defeat and its effects. The case was clearly proved to be one of hyperpiesia.

In this default of instances it seems well therefore to add to our store of evidence by publishing the following notes by Dr. Vey of a case of this kind at University College Hospital. Dr. Vey, then house-physician, watched the patient very closely and made ample clinical notes during the last fifteen months of his life, including the laboratory reports and the post-mortem findings. Dr. Vey described the case in his thesis for M.B. at Cambridge; and, with his permission, I have made (I hope not too

drastic) an abridgement of his notes. I think that I have not omitted any relevant abnormal feature or reaction.

#### *Report of Case by Dr. D. C. L. VEY.*

A male patient, aged 61, a clerk, was admitted into University College Hospital, under Sir John Rose Bradford (and later under Dr. Sidney Martin), five times in fifteen months. The first occasion was on September 3rd, 1921. He had complained of dyspnoea on ascents for ten months, and of swelling of feet and abdomen for nine months. Previous personal history good; no bad habits.

On admission, respiratory rate 32, much general oedema; liver full; heart large and heaving; pulse regular, large in volume, rate 50 to 72. Systolic blood pressure 200. Urine very scanty; specific gravity high; albumin abundant; a few epithelial cells and leucocytes; no casts. Under treatment, which included digitalis, he improved greatly.

Second admission, December 28th, 1921; symptoms as before, but drowsiness also. Bled to 24 oz. Heart still larger, but in seventh left space in mid-axillary line. Second aortic sound much accentuated. Blood urea, on two occasions, 20 and 37. Blood pressure (systolic) 210. Improvement as before. Blood pressure on discharge 180.

On the third and fourth admissions similar reports and results. Fifth admission, November 8th, 1922: oedema and dyspnoea worse than ever; but pulse regular, full and hard, rate 80. Radial thick; blood pressure 190. Heart as before. No murmurs in any area. Urine in first twenty-four hours 34 oz., and about the same for next seven days; specific gravity 1018; some albumin. Head-ache and drowsiness. Respiration at times tidal. No twitchings. Multiple incisions of legs answered well, relieving symptoms; and blood pressure fell a little to 180-200. Urine now generally reached to 70 oz., and on each of two days to 120. Blood urea on admission was 48 mg. per 100 c.cm.; a little less on the two following days. During a period of three weeks the total amount of urea in the urine ranged between 1.5 and 2.5; the total averaged about 40 grams. Chlorides averaged 3 grams daily. Two averaged about 40 grams. On the former date the concentration was 1.6 per cent. at the end of the first hour (vol. 160 c.cm.), and 1.7 per cent. at the end of the second hour. On the second date (vol. 140 c.cm.) at the end of the first hour, and 2.05 per cent. (vol. 224 c.cm.) was noted at the end of the first hour, and 2 per cent. at the end of the second hour. There never had been any pyrexia, and the patient, as before, was doing well, when he had a sudden rigor; he was distressed and speechless; the temperature rose to 104.8°; he became unconscious, and died. The cause of this event was not apparent at the necropsy. A few days before death recent small haemorrhages had been reported in the right fundus oculi, and a single larger one in the left.

The diagnosis during life was very difficult. “Chronic parenchymatous nephritis” was suspected, though the extreme cardiovascular symptoms seemed hardly to confirm the suspicion. Dr. Goodhart in the post-mortem room, before the necropsy, expressed the opinion that “the kidneys would be found normal, or nearly so.”

The relevant features of the necropsy were briefly as follows: Heart, 39 oz.; left ventricle much hypertrophied and dilated, and right ventricle also. Aorta, traces of old syphilis; many patches of atheroma, calcareous and ulcerative. Pulmonary artery and branches dilated, stiff on section, and showed atheromatous patches. Spleen large and fibrotic, with internal thickening of the arterioles, and fat droplets. Liver nutmeg, and some arteriolar thickening. Kidneys each 9 oz.; except that the renal artery was stiff, no abnormal appearance to the eye. Brain normal to the eye. Microscopically the myocardium revealed well marked interstitial fibrosis; no fatty degeneration.

From the kidneys frozen sections were taken and stained with haematoxylin and Scharlach R.; and paraffin sections were stained with haematoxylin and eosin. The larger arteries showed a moderate degree of internal thickening; this was more pronounced in the smaller, especially the interlobular and afferent, but not to obliteration. Fat droplets in the smaller vessels. Glomeruli “surprisingly little affected; a very few showed some atrophic change with fat droplets, but nearly all were remarkably healthy.” The tubules were practically free from change. Interstitial fibrosis was minimal.

Such in epitome is Dr. Vey's record of a case of hyperpiesia, in its later phases thoroughly investigated. That the patient, as was the case with the one mentioned in Addenbrooke's Hospital, died with more or less of uraemic symptoms may, and often do, occur in the “cardiac kidney,” but in case of the patient's amendment pass off entirely. That the syndrome is essentially incidental in these cases, and, in periods of amendment, transitory, has been very fully illustrated by certain French physicians; but as I am writing away from home I cannot give references. Dr. Vey reported drowsiness on the second, third, and fourth admissions; but during the temporary recoveries the uraemia passed off.

Little by little, then, our knowledge of hyperpiesia in its later phases is increasing, yet its causes still lie in obscurity, and, except in early phases, we are gaining but little power of relief. To some amendment we can attain, but in the later issues, and unfortunately these are too often the first symptoms

\* The amounts of protein and salt taken in the diet were not calculated, but the diet was a very light one.

to drive the patient to seek medical advice, cure is out of the question. Venesections do some temporary good—and are useful at critical moments—but frequent repetitions hardly prove acceptable or satisfactory. Calomel still holds its ground as perhaps the best single drug. The high-frequency current (diathermy) is the best of the “symptomatic” remedies, but too often I fail to persuade the x-ray specialists to take much interest in invisible results. In the long run intermittent courses of calomel, diet, regulated life, diversions of mind, and an annual visit to one or other of certain spas seem at present to be all we can do. C. A.

## THE CUTANEOUS TUBERCULIN TEST (PIRQUET):

WITH REFERENCE TO ITS FAILURE IN ADVANCED  
TUBERCULOUS DISEASE IN CHILDHOOD.

BY

CHARLES McNEIL, M.A., M.D., F.R.C.P. EDIN.,

PHYSICIAN, ROYAL EDINBURGH HOSPITAL FOR SICK CHILDREN; LECTURER  
ON DISEASES OF CHILDREN, UNIVERSITY OF EDINBURGH.

THE cutaneous tuberculin test (Pirquet) is now accepted as a delicate indicator of tuberculous infection in childhood—so delicate, indeed, as often to reveal a latent focus, buried out of reach of clinical methods of detection, and producing no effect upon sound health. On the other hand, it is common doctrine that the test fails in a considerable number of cases of advanced and widespread tuberculous disease in childhood. It is enough to say that these failures of the test are admitted by Pirquet himself,<sup>1</sup> by Calmette,<sup>2</sup> and are confirmed by many published investigations, of which those of McLean and Jeidell,<sup>3</sup> and Dunn and Cohen,<sup>4</sup> may be quoted as representative and recent.

It would seem rash to question such weighty scientific teaching and general clinical experience, and in a previous communication to the BRITISH MEDICAL JOURNAL (1909)<sup>5</sup> I have myself subscribed to the frequent failure of the test in advanced tuberculous disease. But for some time I have used a more careful technique in the performance and reading of the Pirquet test, and with this I have not failed to obtain a positive reaction in any case of severe tuberculous disease proved to be such by the discovery of the bacillus or by *post-mortem* examination. It seems worth while, therefore, to describe this technique and to give some examples of its results.

### TECHNIQUE OF THE PIRQUET TEST.

There is great variation in the directions given for the performance and reading of the test. Undiluted tuberculin is now generally advised, but a dilution is permitted by Calmette and others. For the preparation of the skin, multiple scratches or a single scratch, or the use of a dental burr or small chisel (Pirquet), are variously recommended. The test is advised to be read as positive or negative in twenty-four hours, or at latest forty-eight hours, though it is admitted that late reactions may occur after this time. The control test is made by a similar lesion on the dry skin and the application of a drop of normal saline. The technique which I now use, and which is, I think, more thorough and less free from error, is as follows:

1. *Undiluted Old Tuberculin (O.T. Koch) must be used.*—In my first series of cases, published in the JOURNAL in 1909, a 25 per cent. dilution of old tuberculin was used, and it is very probable that some of the failures there recorded were due to this. Calmette himself still advises such a dilution. In another paper<sup>6</sup> I have published photographs showing the simultaneous use of undiluted tuberculin and 25 per cent. dilution in two cases, and the diminution of the test in the one case and its failure in the other with the diluted tuberculin. It is necessary, therefore, to emphasize the importance of using undiluted old tuberculin for the cutaneous test.

2. *Preparation of an Area of Skin to Ensure Contact of the Tuberculin with Vascular Tissue.*—The method of the single scratch, or of a number of scratches, is too haphazard. Pirquet's method of placing a drop of tuberculin on the skin and of making a lesion by rotating through it a small drill or borer, may also fail to reach and expose the vascular cutis. I always use the following method: A small circular area of skin on the front of the forearm is chafed with the sharp point of a darning-needle until the epidermis is removed and the pink cutis vera is exposed. Care is taken to avoid bleeding. The eye of the needle is now charged with un-

diluted old tuberculin, and pressed into the prepared vascular surface with a rotary motion. A small bruised pit is thus formed from which the tuberculin is rapidly absorbed. This procedure is similar to that advised by Pirquet; but it differs in the careful preliminary excoriation of the skin, and thus renders more certain the contact of tuberculin with the skin capillaries; this difference is enough, I think, to secure success in cases where the tuberculin reaction is feeble. In seven cases in which both methods were tried side by side the reaction was positive in five with the method just recommended, and in only two with Pirquet's method. The reaction is a vascular reaction, and it is only after a careful removal of the tough epidermis that contact with the blood vessels of the skin can be ensured.

3. *The Time-Reading of the Test.*—The routine in clinical work is to read the test as positive or negative at the end of twenty-four hours, and later observations are seldom made. This is another source of fallacy. It may be granted that in a large majority of cases a positive reaction is visible after one day; but it is quite common for the reaction to be delayed until the end of two or three, or rarely four days. Therefore, though a test may be pronounced positive at the end of one day, it is never safe to record it negative until four days have elapsed. I shall give presently an example (Case 1) of how easy it is to make mistakes when, in the routine of clinical work, the arm is examined after twenty-four hours, is recorded as negative, and is never looked at again.

In a previous paper<sup>7</sup> I suggested the definition of a positive reaction as a “red papule that persists for seven days.” Since that was written in 1909 my subsequent experience has confirmed me in this definition. Calmette<sup>8</sup> states that the reaction generally disappears in “a few days.” I have watched the behaviour of many positive reactions for weeks. Even in feeble reactions I have never failed to see a dark discoloured papule at the end of two weeks; and it is common to see clear evidence of a positive reaction at the end of a month. The tuberculin cutaneous reaction is a chronic enduring reaction: it may be slow in appearing, but it is always long lasting; and in that respect it shows its kinship to the slow inflammation of a true tuberculous process. There need be no fear that if a test has not been read until after a week a positive reaction may have come and gone in that time. It is worth repeating that while a positive reaction may be recorded after a day, a negative reaction (and this is the more valuable clinical aid) may not be accepted until at least four days have elapsed. It would be a safer, though perhaps less convenient, way to read the test at the end of a week rather than at the end of a day. In all important and doubtful cases the practice of observing the arm daily for a week is to be recommended.

The size of the papule is of little importance. It generally exceeds 5 mm. with the above technique; but in a few cases is less than that, and yet is to be regarded as positive if it persists for a week.

4. *The Use of a Control.*—Up to a few months ago the control I used was a 50 per cent. solution of glycerin and water. Since then I have used normal horse serum, which has proved a more severe control, as it gives not seldom a small inflammatory papule. This, however, has always disappeared in four days. But its appearance makes it necessary to delay the recording of a small or doubtful positive reaction until this time has elapsed; if this is not done, pseudo-reactions, sometimes called traumatic reactions, may be accepted as true positives. It will thus be seen that the practice of reading the cutaneous reaction at the end of one day may introduce two kinds of fallacy: it may omit late and feeble positive reactions which may develop after a day; and it may include false positive reactions which will have disappeared in a few days. But the use of a normal serum control ought to guard against the latter fallacy.

There are obstinate critics who argue that any albuminous substance rubbed into the skin may produce an inflammatory reaction, and who put no faith in the specific character of the tuberculin test. Such an argument can neither be proved nor disproved. But *post-mortem* evidence, which has now been produced in great amount, makes it reasonably certain that a positive cutaneous reaction indicates a tuberculous focus in the body.

### Alleged Failure of Test in Advanced Tuberculous Disease.

I shall now cite a few examples from my own experience to show that, with the technique just described, positive reactions can be obtained in cases of massive and advanced

tuberculosis in children. With the above technique I have not failed so far to obtain a positive reaction in any case of tuberculous meningitis, acute miliary tuberculosis, massive abdominal tuberculosis, and acute pulmonary phthisis.

*Case 1.*—Mary F., aged 11 years; acute phthisis. Admitted June 3rd, 1921. Great emaciation and weakness. Large hard mass of glands in the right side of neck; signs of consolidation and catarrh in the right lung. Cutaneous test, performed June 5th, was negative two days later; the child was not seen again until June 23rd, when the reaction was positive. A second test, done on June 23rd, was positive. July 25th: emaciation and weakness extreme; tubercle bacilli in sputum; third cutaneous test positive. Death, sixteen days later. No post-mortem examination.

*Case 2.*—Charles S., aged 13 months; pulmonary and miliary tuberculosis. Admitted December 3rd, 1921, with fever, emaciation, and weakness. Signs of consolidation in right middle lobe of lung; rapid progress of disease. Cutaneous test, made nine days before death, positive. Post-mortem examination showed tuberculous bronchopneumonia of right middle lobe; miliary tubercles in both lungs, liver, and spleen; and tuberculous mediastinal glands.

*Case 3.*—Francis C., aged 15 months; general tuberculosis. Admitted February 1st, 1922, in extreme weakness and emaciation; death in twelve days. Cutaneous test positive six days before death. Post-mortem examination showed tuberculous cervical and mediastinal glands; large miliary tubercles in both lungs, especially the left; tuberculous ulcers in intestine, and tuberculous mesenteric glands; miliary tubercles in liver, spleen, and kidneys.

These cases have been selected because of the extensive or acute nature of the disease, and also because a positive test was obtained in an extremity of weakness and emaciation and within a few days of death.

McLean and Jeidell,<sup>3</sup> in a report on 3,742 Pirquet tests in young children, found 44 negative reactions in cases proved to be tuberculous by autopsy or by the discovery of tubercle bacilli during life. The technique of the test was as follows:

"Two light scratches were made approximately 1/4 in. in length and 2 in. apart. Into one scratch the tuberculin (undiluted O.P.) was lightly rubbed with a toothpick having a flat end; the other scratch was used as a control. In doubtful cases the test was repeated. It was not usually considered negative until forty-eight hours after application."

Dunn and Cohen,<sup>4</sup> in reporting failures of the test in a considerable number of cases of tuberculous meningitis, peritonitis, and miliary tuberculosis, give no account of the technique of making and reading the test. It may be presumed that it was carried out in a similar way. There is no doubt that their experience of failure in advanced tuberculosis is amply confirmed by other investigations employing a similar technique.

My own experience with a different technique is as yet small compared with that of the investigators mentioned, but it has included every type of tuberculous case, and it suggests that when care is taken to apply tuberculin thoroughly to the skin, and that when the standard of a negative test in severe disease with weakness and emaciation is not the absence of reaction in one or two but in seven days, the Pirquet test does not fail even in massive tuberculous disease. If further experience should confirm this, the clinical significance of a negative test will be increased; it will then absolutely exclude tuberculous disease. But the technique of the test will require modification on the lines laid down in the present paper.

One other point may be briefly mentioned. I am not as yet prepared to say that with this improved technique positive tests can be obtained in acute illnesses, such as pneumonia or measles, with an underlying tuberculous infection. At present I am trying to collect evidence on this point. In any case, the point is not of clinical importance; a considerable personal experience of such cases with the ordinary technique has shown me that a positive reaction can be obtained soon after the crisis of the acute illness.

## THE THERAPEUTIC USE OF TUBERCULIN.

BY  
W. CAMAC WILKINSON, M.D. (LOND.), F.R.C.P.,  
LATE LECTURER IN MEDICINE, SYDNEY UNIVERSITY.

Views on the use and value of tuberculin are so various, discrepant, and contradictory that no final judgement can be reached until the actual protocols of evidence are produced and submitted to a close and searching analysis and criticism by a judicial tribunal that recognizes the distinction between evidence and comment or assertion. Guessing in the process of diagnosis and uncertainty in the evaluation of essentially different methods of treatment should be excluded.

The diagnosis must be based upon the presence of tubercle bacilli in the discharges from the affected parts or organs; and since in all but pulmonary cases in adults and in all cases in children it is impossible to determine whether the disease is due to the bovine or to the human type of bacillus, these cases should be excluded. Pulmonary tuberculosis in adults with tubercle bacilli in the phlegm is almost invariably due to the specific action of the human type of bacillus, and therefore constitutes the ideal material for determining the value and trustworthiness of tuberculin in treatment and even in diagnosis. Another cogent reason why pulmonary tuberculosis should be selected for this investigation is that this is the prominent lesion in almost 90 per cent. of all the serious forms of tuberculosis in man; and of the remaining 10 per cent. at least half may be reasonably traced to pulmonary tuberculosis.

Long ago I laid it down that in testing the value of any method of treating pulmonary tuberculosis, logic required that no other system should be used. At the Tuberculin Dispensary we allowed patients to continue their life as usual, neither insisting upon the "open window" nor using drugs, and only giving extra food when it was quite obvious that the patient had not the money to buy enough food to maintain normal nutrition. Pulmonary tuberculosis is, however, a very variable disease, because both soil and seed vary. Inherent qualities, often inherited, in the individual, age, local conditions of the lungs, sometimes created by certain infections, such as measles, whooping-cough, and influenza, which may convert a latent into an active process of tuberculosis, and general biochemical anomalies in the tissues, blood, and lymphatics (deficiency of endocrines, deficient calcium, malnutrition), are among the factors in the soil that favour definite disease. The seed also varies in quality, virulence, and quantity, but there is no clinical way of measuring these variations. Accordingly one must not draw conclusions from the results, whether good or bad, in a few cases, must not select cases, and must not publish anything short of a series of at least fifty consecutive cases in various stages of the disease treated exclusively with the remedy to be tested.

After a full course of treatment the cases must be examined regularly two or three times every year for three years, and then once a year at least for another three to five years. Anything less than supervision for five years spoils the investigation, because it is well known that early stages of tuberculosis without any treatment may not become serious for four or five years. For cases treated in the second stage five years may be considered ample, but in my investigation there has been supervision for eight years and more. The control of these cases is very difficult among the poor, who constantly change their home; and during the war the difficulties were intensified. Nevertheless this exacting condition is essential, because the sure test of the value of any method lies in the duration of life after treatment has begun. The length of life, ability to work, sense of energy, the state of the pulse and appetite, even the appearance of the patient to the practised eye, and especially the evidence in changes in the quality and amount of the phlegm, furnish more useful evidence of improvement than the most meticulous description of physical signs. Paying due respect to these exacting conditions, I am prepared to produce evidence which goes to prove that the method, which I have evolved from a continuous experience since the earliest days of tuberculin, yields results far better than any I have seen published in any English, German, or American literature. Tuberculin has not had a fair trial in England, except at the hands of myself and a few of my pupils, who soon learnt from experience that tuberculin, used in accordance with definite principles, is quite free from danger, and that the timid use of tuberculin is a poor substitute for

the method of increasing doses, controlled exclusively by a meticulous regard for the clinical signs, manifested in variations in temperature, in weight, and in pulse rate.

The value of tuberculin treatment cannot be accurately assessed in children affected with enlarged cervical glands. The reasons are obvious to those familiar with the varying nature of glandular swellings in children, especially between the ages of 5 and 15. At this age period children are liable to suffer from many sorts of gland swellings, quite independent of tuberculosis. Further, except by operation and laborious investigations, one cannot say whether the swelling is due to infection with human or bovine tubercle bacilli or with other infective agents.

In certain cities, notably Edinburgh, the bovine tubercle bacillus is shown to be a very common cause of enlarged cervical glands, and the concentration of these forms of gland tuberculosis in children's hospitals may give a wholly wrong impression of the prevalence of tuberculosis in children even in Edinburgh. There is certainly some evidence that in children over 5 years of age the bovine type of tubercle bacilli causes lesions more prone to regress and to become fibrotic than those induced by the human type. In Edinburgh especially any deductions based upon the effects of tuberculin in tuberculosis of the cervical glands in children must be suspect.

Statistics show that in children between the ages of 5 and 15 the mortality from tuberculosis is one-third to one-fifth of that in the earlier years of life, and one-fifth to one-tenth of that in the later years. It would seem that at this period the human tissues acquire a special resistance, and at no other period is this natural resistance greater. I have suggested that this remarkable immunity during these years is due to mild infections with bovine tubercle bacilli in early life. The great prevalence of general tuberculosis, and of tuberculosis of the udder in dairy cows, justifies the assumption that very few children can be expected to escape the risk of infection with bovine tubercle bacilli by the lymphatics of the mouth and cervical glands and other sections of the alimentary tract. These mild infections explain, too, why so many young children, all of whom drink cow's milk, give a von Pirquet reaction. The value of this reaction as a diagnostic test must therefore be discounted; it is just the cutaneous expression of these mild infections. These lesions tend to regress at this period. My own inclination is to the view that if the lesions do not regress the infective agent is more likely to be the human type of bacilli. Certainly the frequency of a von Pirquet reaction does not indicate the frequency of infection by the human type of tubercle bacillus. But the main point I wish to urge is that with so many indeterminate variants in the processes of gland tuberculosis in children, especially between the ages of 5 and 15, children of this age furnish about the very worst material for affording clear evidence as to the value of tuberculin either in diagnosis or treatment. Hundreds of children between these ages are taken to the seaside, and of course improve, because at these ages the natural tendency is towards improvement. No harm is done. Margate is better than London, if people can afford it, but it is not proved by any means that Margate air has cured the tuberculosis because the symptoms and signs regress. The symptoms and signs would have regressed if the child had stayed in London. The test of the value of Margate air must be made at a time of life when this disturbing age factor is eliminated. In like manner Sir Robert Philip's opinions must remain suspect until he gives proof that the subjects of his experiments with inunctions of tuberculin did not belong to this age period, distinguished by an extraordinary phase of immunity.

With much that Sir Robert Philip has stated I agree; I have expressed the same views again and again. But good observer though Petruschky is, I do not approve of his method of dosage, and I do not trust his method of inunction. The test of the relative value of different methods of using tuberculin depends upon the duration of life after treatment in a series of cases of similar character. Years ago I came to the conclusion that the minimum dose for securing permanent results was at least 0.6 c.cm. of the stronger preparations. This opinion is based upon more than twenty-five years' continuous experience in hundreds of cases, in various stages. Shortly before his death, when I related this experience to Professor Koch, he said:

"That is remarkable. We have proved, by complement fixation tests, that 0.5 c.cm. must be given before antibodies can be demonstrated in the blood; while not less than 0.3 c.cm. neutralizes a pre-existing von Pirquet reaction."

I have also shown, by some experiments independently controlled, that, after large doses, the opsonic index may be raised to 2 and even 3, and there is no negative phase of any duration. Moreover, in 1906, I proved, by Arnet's method, that, after large doses of tuberculin, a great improvement occurs in the character of the leucocytes, which probably play a part in the production and action of antibodies. Apart from these laboratory methods I have shown that the subcutaneous injection is a simple, painless, and accurate means of exhibiting tuberculin. I can produce the protocols as evidence at any time, and, while my methods may be far from perfect, I can only be convinced by the details of protocols in evidence that Sir R. Philip can in any way approach the success I have achieved by large doses given subcutaneously.

Subcutaneous injections, given properly and in the proper place, are not painful; and young children, properly handled, rarely ever shed a tear. Ten years' experience at the dispensary proves this. The subcutaneous method is painless, and is free from danger in competent hands; my thirty years' experience convinces me of this. And after three years' experience at my Tuberculin Dispensary, all the doctors assisting me wrote to the *BRITISH MEDICAL JOURNAL* and subscribed to this view. The subcutaneous method is the best way of giving large and progressively increasing doses—perhaps the only way—as all of the tuberculin passes into the circulation. There is no way of telling how much tuberculin may be absorbed by inunction, and Sir R. Philip does not mention any maximum dose. It would vary with the type of skin, sex, age, temperature, and other conditions. Possibly inunction has an advantage when the lesions are localized in the cervical glands. The lymphatics of the skin drain certain areas, and the lymph makes straight for the associated glands of these areas. Hence inunctions would favourably affect these glands harbouring the bovine type of bacillus. But the dominating purpose in the treatment of tuberculosis in man is, not to treat these mild conditions due to bovine tubercle bacilli, but to treat all tuberculous lesions in the body, and above everything the more dangerous lesions, associated with the presence of the human strain of bacillus, in the lungs, kidneys, deep glands of the body, and in serous membranes. On anatomical grounds I cannot see that inunctions can be as effective as subcutaneous doses in tuberculosis of bones or joints. Tuberculin is not a counter-irritant.

Except in lupus and tuberculosis of the cervical glands, tuberculosis is mostly situated in parts which can be best approached by large doses through the general circulation. No doubt in subcutaneous injections tuberculin travels also by the lymphatics, and may cause the lymphatic glands to swell; but the crux of the argument is the success achieved by the methods in question. In cases of pulmonary tuberculosis treated in 1910, 1911, and 1912 at the Tuberculin Dispensary, these are the results:

In cases in Stage I, with tubercle bacilli in the phlegm, no death was known to have occurred in any case from tuberculosis in the succeeding ten years. In cases in Stage II, with tubercle bacilli in the phlegm, 67 per cent. were proved to be alive nine years later. In fact in Stages I and II, after a period of nine years, 72 per cent. were still alive and able to work.

The success or failure of any method depends exclusively upon the results obtained in these stages of the disease (Stages I and II). If Sir R. Philip will produce the protocols of any similar consecutive cases of pulmonary tuberculosis, with tubercle bacilli in the phlegm, treated by the percutaneous method (inunction), I am ready to produce my protocols and leave the decision in the hands of an unbiased tribunal.

Dr. William Gordon<sup>2</sup> has given a comparison of results, four years after treatment, at different sanatoriums in cases (open and closed) in Stage I as follows:

Frimley	...	...	...	15 per cent. dead
Midhurst	...	...	...	20 " "
"London cases" (Dr. Bardswell)	...	...	...	31 " "

The Brompton Hospital Reports show that in 86 cases in Stage I with tubercle bacilli in the phlegm treated in 1905, 1906, and 1907, and checked by after-examinations up to 1912 (four to seven years after treatment), the results were 23 dead and 29 lost sight of. This is equivalent to 23 deaths out of 57 cases in the course of the four to seven subsequent years—a death rate of over 40 per cent.

In 1910, 1911, 1912, and part of 1913 I treated with large doses of tuberculin (TA) alone (as a rule a final dose of 1 c.cm.) 166 early cases, of which 16 had tubercle bacilli in

the phlegm, and I had not a single death from tuberculosis to record down to the year 1920. Moreover, I had one striking control case.

A young boy was brought to us. He had positive physical signs at one apex, and at the Lister Institute a few tubercle bacilli were found in his phlegm. We treated him for two months and he gained 2 lb. and improved very much. Unfortunately we notified the mother to take the boy to Brompton Hospital. I lost sight of the boy for more than a year, when the mother told me the tragic story. At the instance of the lay visitor the boy went to Brompton and was six weeks in the hospital for observation. The mother was then told that the boy had not tuberculosis. (Tubercle bacilli had been found by us.) When I saw the boy again he was in a hopeless third stage, and he died in a few months. Our diagnosis was tragically confirmed.

Thus the only early case that we were not allowed to treat died within two years; surely a striking control. These results obtained by me in England almost exactly tally with the results I have published in my book.<sup>2</sup> My records in Australia and London are quite good enough to give me unswerving faith in large doses of tuberculin given subcutaneously as easily the best remedy for tuberculosis in all its forms.

## THE TREATMENT OF PNEUMONIA.\*

BY

A. G. NEWELL, M.D., D.P.H.,

HARRINGAY.

PNEUMONIA causes more deaths than tuberculosis, and more people die from it between the ages of 35 and 55 than at any other period. It carries away insidiously the aged without an acute attack. The death rate is put at 20 per cent., and with influenza at 30 per cent. This means one death out of every five or six patients; annually over 40,000 persons die from it.

Pneumonia at its outset is a septicaemia caused by a diplococcus. All its symptoms are the result of the influence of the bacillary toxin on the nervous system. Its entrance is always at some local focus of the lung evidenced early by dullness and diminished air entry, but its spread is often very rapid. Hence the importance of the early localization and diagnosis and active measures.

The early attempt at defence is consolidation, to limit the focus of infection; the organisms are surrounded, and there is a leucocytosis whereby the phagocytic action of certain blood cells destroys the organisms. It must be remembered that the lungs contain a larger number of leucocytes than any other organ, except the marrow (their birthplace) and the spleen (their grave). The clotting of the fibrinous exudate in the alveoli which gives rise to consolidation, and the attack by emigration into this of the leucocytes shows an attempt on the part of Nature to localize the infection and prevent its spread. But leakage occurs, and before consolidation takes place certain organisms and toxins have already spread to the blood, causing the acute septicaemic symptoms. Nature's third attempt at defence is the formation of antibodies. Let me summarize the main principles, as it appears to me, on which we should go in attempting to counteract the septicaemia.

There is acute nerve exhaustion from intoxication. This demands absolute rest. The least movement of the patient is exhausting, especially any efforts by himself. Once the diagnosis is made he should not be moved for examination. He should not be allowed to do anything, and bed pans and urine glasses are essential. With this acute nerve exhaustion there is nerve exhaustion to the heart from the poisoning of the vasomotor centre and of the heart muscle. Therefore the importance of rest is especially demanded by an organ called upon to do extra work by the resistance to the circulation in the lung alveoli. A patient may fall back dead on attempting to sit up. The consolidation of the lung alveoli lessens the oxygenation of the blood, and has therefore thrown out of action a defensive auxiliary of the blood. This demands free ventilation around the patient.

The high temperature, the rapid breathing, rapid pulse, the

pain, all add to the patient's discomfort, and therefore it is essential that his comfort and his environment should be attended to by a skilled nurse, or one to whom all the particulars of the necessary details are made plain.

Various lines of treatment have been adopted in the past:

1. Active bleeding and purgation; its ancient history and objects are well known, and I need not dwell on this.

2. Poultices and expectorants may be said to have died out.

3. "Expectant" treatment may be summed up as doing what each individual fancies best. Where groups of cases have been treated by certain definite drugs it has not infrequently been claimed that some of them were "specific"; types of cases may vary greatly in severity, according to the virulence of the organism, or the influence of the locality, or of the acquired natural resistance, so that claims founded on statistics are of little value. I believe at present there is no specific drug for this disease. Any drug to be specific, or any combination of two drugs to deserve such a claim, must show equal results in the hands of any practitioner anywhere. By the expectant treatment thousands of lives are lost annually.

4. "Chloroform" treatment has been used in America. Its object was to give rest to the inflamed lung. It has not had, so far as I know, a long run. It aids, in my opinion, the basic factors causing the distress, and can have no influence on the intoxication.

5. The application of ice has been advocated by many, the late Dr. David Lees among others, and has been tried in Dublin hospitals. It demands the earliest recognition of the disease—the localization at its earliest site. Two ice-bags are placed so as to include between them the inflamed lung. It has a scientific and rational basis, and good results have followed its use. The pneumococcus is very sensitive to changes of temperature, and will not live below 28° C., nor above 42° C.—the optimum being 37.5° C. The greater the virulence of the organism the more marked its sensitiveness to temperature. The ice inhibits its multiplication, lowers the patient's temperature, adds to his comfort, and is helpful to sleep. I have often used ice in high temperatures with benefit. In general practice no doubt public opinion would be shocked, but it is of great use to give ice to suck. Chills do not occur. It takes time to reduce high temperatures by rubbing with ice, but the sensation is comforting. I have often seen and used ice for the hyperpyrexia of sunstroke, the whole naked body being on blocks of ice and rubbed with ice.

6. The object of lung puncture is to cause a local accumulation of polymorphonuclear leucocytes by setting up a focus of irritation in the pneumonic areas and so stimulating phagocytosis. It is applying to the lung Kraske's principle in the local treatment of erysipelas, his treatment for the latter disease being to make superficial incisions about an inch or two from the spreading margin all round the affected part. It is considered analogous to laparotomy in the aseptic variety of tuberculous peritonitis. This line of treatment demands accurate determinations of situation and area, consolidated patches; a hollow needle or trocar about 1½ inches long is put into the consolidated patch and left there for thirty seconds. If more than one patch is present, frequently general practitioners get these cases with many, the largest is selected, and if there are several large patches other punctures are made. Strict asepsis is essential, and the best sites are said to be the axillary lines. Striking results have been claimed by its advocates, but as a method for general practice it does not seem desirable with other measures yet available.

7. Studies at the Rockefeller Institute of Medical Research (referred to in the memorandum on pneumonia issued by the Local Government Board in 1919) led to the recognition of four types of pneumococcus; so far antipneumonia serum has been found effective only in cases due to Type 1. In so acute a disease we cannot afford to wait for the determination of the type, and as the serum has to be injected every eight hours it is out of court in general practice.

A bright hope lies in the success attending vaccine treatment. Recovery depends on the patient providing sufficient antibodies against the bacteria and their toxins in the blood; this and this only is the specific treatment available. Early diagnosis is essential: given during the first twenty-four hours, brilliant results have been obtained. A vaccine must be used early, and it is not necessary to wait for a vaccine to be prepared. By the use of vaccine we are helping Nature, and by accumulating antibodies in the blood we have them available for the lung when the fibrin has been liquefied. In other septicaemias (streptococcus, staphylococcus, gonococcus, B. coli, etc.) vaccines have been successful. Should we not

\* A paper read before the North Middlesex Division of the British Medical Association.

all adopt this method and see the result on all hands? Is the gravity of the disease and the saving of life not sufficient to warrant its trial? I think it is. Dr. Wynn of Birmingham says:

"I know nothing in the whole range of medical treatment so dramatic as the rapid defervescence which follows the injection of a suitable dose of vaccine to a patient suffering from pneumonia or influenzal pneumonia within twenty-four hours of its onset. The vaccine I have used is made from primary cultures or at most first subcultures. It should not be detoxicated or sensitized. For acute pneumonia it contains several strains of pneumococci. . . . The important points are that it should be given early and in sufficient amount."

He gives 100 million pneumococci to an adult; to a child aged 12 to 14 he gives 40 to 50 million, and to a child aged 2 to 3 years 10 to 20 million. These doses have been arrived at after many years of experience. When such a dose is used during the first day of the disease, in the majority of cases the temperature falls to normal on the day following and no further treatment is required. By each day's delay defervescence is less likely, and the dose has to be repeated every twenty-four hours until the temperature is normal. His results\* show:

Day Treated.	No. of Cases.	Recoveries.	Deaths.	Temp. Normal in —	
				24 hours.	48 hours.
First	23	23	Nil	Per cent. 7.4	Per cent. 15.7
Second	23	22	1	47.85	55.5
Third	22	23	2	50.0	50.0
Fourth	10	15	5	30.0	43.0
Fifth	14	12	2	35.7	63.5
	107	97	10	50.0	65.0

In pneumonia there is no evidence of a negative phase, and so the early large dose is given safely.

Stock vaccines should be used from first cultures and from a highly virulent strain. Even if a case is injected from a stock vaccine and the case does not afterwards develop consolidation, no harm is done. No harm is done by using antitoxin for a suspected case of diphtheria. Sir Almroth Wright, in his work on the use of vaccines in pneumonia, states that inoculation in the form of a single large dose, administered in the incubation period, often arrested the disease and prevented death. I put this method forward with a plea for trial, as it seems to me our best line of action for the future. My results from stock vaccines are striking.

I cannot lay too much stress on the hygiene of the room—free ventilation is essential. Cases have been treated in America in all weathers on the roofs of hospitals, and in the Philadelphia General Hospital, where the cases were of unusual severity, the death rate of 53 per cent. before the adoption of the open-air treatment was reduced after its adoption to 38 per cent. In the Prince Edward Hospital, Sydney, the patients have since 1908 been treated in the open day and night, and have recovered more rapidly and with less complications and less necessity for drugs. I always advise the windows to be well opened, and so long as there is no discomfort from draughts and there is sufficient light covering, no harm will accrue. Overheating of the room should be avoided—the patient is already hot enough; fresh air is the best germicide, and the patient is gasping for a cooler air.

The actual degree of temperature is of little scientific interest, as one can usually tell from the skin and the pulse the existence of a feverish state. Its record is of value to the nurse to avoid too heavy clothing and at a crisis for more. There is a tendency to put on too much covering both by nurses and relatives. It adds to the discomfort of a feverish patient. If the patient is hot it is well he should lose heat. Pneumonia jackets are useful provided they are thin and not too heavy.

Pulse and breathing rates should always be recorded. The respiration-pulse ratio normally is 1:4; but in pneumonia it may be 1:3, 1:2, 1:2.5, 1:1, or even 2:1. It is the index factor of how the patient is going, and helps in prognosis under ordinary lines of treatment. A case is not necessarily hopeless with 1:1. The heart condition decides.

Potassium iodide and creosote have been advocated. With a tuberculous focus it is possible to loosen some fibrous tissue of a semi-healed area. Inunction of 10 minims of pure creosote in half an ounce of water, with or without one drop of oil of peppermint, has been used with success; it causes sweating and, it is claimed, aborts the disease. One of the oldest and best drugs is calomel. Digitalis is recommended from the outset by some, strophanthus by others. Neither of them raises blood pressure, and the cardiac muscle is enabled to act with regular impulse. They are the only cardiac stimulants necessary, and if employed should be used from the outset. Strychnine and alcohol are probably of little avail. Tincture of nux vomica with digitalis is better than injections of strychnine for a flagging heart. To produce sleep 1/6 grain heroin may be given: 5 to 10 grains of Dover's powder in a saline has been recommended, but I never use it. Paraldehyde in doses of 1 to 2 drachms in very sweet tea is safe. Soap liniment will relieve localized pleuritic pain. For heart failure injection of 10 per cent. glucose is said to be the most valuable measure.

The cyanosis depends on anaemia of the arterial blood, and if oxygen is administered properly and by a suitable apparatus, such as Haldane's, it has been proved that this anaemia will be diminished and so the cyanosis relieved. Otherwise it is probably useless. Too often it is used as a last resource when nothing could be achieved. It is more important to let the fresh air into the room from the very outset.

As regards diet, milk (citrated if there is vomiting), with soda-water or barley water, or a little flavour of tea, or malted milk may be given. All sugars are good for the heart, so from the outset sugar or honey should be given. Water is essential in small quantities, as also is ice. Two pints of water should be given in the day—albumin water or water flavoured with beef-tea; beef-tea alone is not advisable. The mouth should be cleaned every two hours.

## PERNICIOUS ANAEMIA WITH FOCI OF INFECTION IN THE ALIMENTARY TRACT.

BY

VINCENT COATES, M.C., M.D., M.A. CANTAB.,

PHYSICIAN, ROYAL MINERAL WATER HOSPITAL, BATH; ASSISTANT PHYSICIAN,  
ROYAL UNITED HOSPITAL, BATH.

It has long been held that foci in the alimentary tract may play an important part in the production of pernicious anaemia; it has not been clearly established exactly how this obtains, and the theory does not reconcile the facts that, whereas pernicious anaemia is comparatively uncommon, septic foci are relatively of frequent occurrence.

Hurst<sup>1</sup> believes that achlorhydria is almost invariably the predisposing cause. He collected 12 cases in which this was known to have preceded the onset of anaemia by periods of from one to twelve years. He considers the absence of HCl, probably in the majority of cases of constitutional origin, to be the important factor, and not the cause of the absence. According to him the achlorhydria not only favours infection but results in the arrival in the intestine of proteins in an unaltered condition. He classifies the possible results which may accrue from achlorhydria thus:

1. Delayed protein digestion, with an undus proportion remaining in the lower part of the ileum, in a form readily prone to bacterial decomposition.
2. Provision of material likely to form toxins, which may be (a) haemolytic, the cause of the anaemia; (b) neuro-toxic, causing subacute combined degeneration of the spinal cord; (c) a toxin stimulating bone marrow to form abnormal types of red blood cells.

The fact that subacute combined degeneration of the cord may appear with little or no evidence of blood changes in no particular detracts from the likelihood of the above theory being practically possible, and this is enhanced in value by the good results Büttner and Werner<sup>2</sup> obtained by duodenal lavage. Nor does the order in which changes may appear in the blood or in the cord. On the other hand, Biffi<sup>3</sup> states that achylia gastrica may be absent, and that it occurs later than the blood changes. Maynard and Sturton<sup>4</sup> record two cases of pernicious anaemia with foci in the alimentary tract, one with dental sepsis and the other with colitis. The autopsy of the latter showed ulcers in the ileum. They

\* *Lancet*, September 2nd, 1922, p. 535.

It is mainly because of the prominence of the alimentary lesions that the following three cases are described.

### CASE I.

W. D., male, aged 39, was admitted to hospital for dysentery on December 13th, 1921, with a history of having had malaria, gastritis, colitis, and dysentery in 1919 while in India and Mesopotamia. In April, 1919, examination of stools, liver, and spleen proved negative. In January, 1920, the spleen was palpable and there was tenderness of the descending colon; some carious teeth were removed. In June, 1921, he was sallow, and there was tenderness of the colon; the liver and spleen showed nothing abnormal.

On examination the patient was sallow and anaemic; the mouth was clean; nothing gross was detected in heart, lungs, or abdomen. Blood pressure 96. There was oedema of feet. The urine was normal; examination of stools repeatedly negative. There was nothing to note in the central nervous system except marked pallor of the optic discs without haemorrhages. A test meal gave no free HCl. The Wassermann reaction was negative. Examination of the blood showed:

Red corpuscles	...	...	...	...	1,370,000
White corpuscles	...	...	...	...	2,700
Haemoglobin	...	...	...	...	37 per cent.
Colour index	...	...	...	...	1.5
Differential count—					
Polymorphonuclears	...	...	...	...	45 per cent.
Lymphocytes	...	...	...	...	48 "
Large mononuclears	...	...	...	...	6 "
Eosinophiles	...	...	...	...	1 "

Microcytes, megalocytes, and poikilocytes were present. There were no normoblasts nor megaloblasts.

*Course.*—There was occasional slight to moderate rise of temperature. Severe vomiting for one week. The liver became easily palpable. After several courses of arsenic and drachm doses of dilute HCl with his meals, he was discharged, after five months, with a blood count of nearly 5 million red cells and 3,000 white, and a colour index of just over 1, declaring himself well. The spleen could never be felt, and no megaloblasts were ever seen.

### CASE II.

G. S. C., male, aged 23, was admitted to hospital for sprue on November 21st, 1922. He had had jaundice and diarrhoea when in China from November, 1919, till May, 1920. In London, in 1921, he was treated for sprue by alkalis, pancreatic extract, *B. coli* autogenous vaccine, and by dieting. He gave a history of frequent copious stools, sore mouth and tongue, and much flatulence.

Examination showed: marked pallor of membranes; much emaciation with dry scaly skin. Teeth excellent; tongue smooth and ulcerated. There was no enlargement of the heart; apex beat fixed; reduplicated basal second sound. Early clubbing of fingers. Blood pressure, 88. Friction over lower half of lung from base to heart's apex. No tubercle bacilli had ever been found in the sputum. The abdomen was doughy and distended; liver dullness decreased. The stools were copious, acid, and frothy, with excess of fat, and yielded a plentiful growth of *B. coli* and streptococci; yeasts also were present, but no protozoa. There was nothing abnormal in the central nervous system except marked pallor of the optic discs without haemorrhages. The patient was too ill for analysis of the gastric contents. Examination of the blood showed:

Red corpuscles	...	...	...	...	1,500,000
White corpuscles	...	...	...	...	2,000
Haemoglobin	...	...	...	...	40 per cent.
Colour index	...	...	...	...	1.4
Differential count—					
Polymorphonuclears	...	...	...	...	45 per cent.
Lymphocytes	...	...	...	...	52 "
Large mononuclears	...	...	...	...	3 "

Polychromatophilia, anisocytosis, and poikilocytosis were present. There were two normoblasts and many megakaryocytes.

*Course.*—There was an occasional rise of temperature; petechial haemorrhages; loss of left knee-jerk. Hypostatic pneumonia developed, and death took place on February 8th, 1922, in spite of all forms of treatment, both dietetic and therapeutic. No *post-mortem* examination was obtained.

### CASE III.

W. A., male, aged 34, was admitted to hospital for dysentery on September 16th, 1922. His history showed that he had had bacillary dysentery in August, 1918, and malaria in September, 1919. In January, 1920, however, he suffered from no disability. In April, 1920, he had his teeth attended to. In February, 1921, the spleen was palpable. He complained of loss of appetite, sore tongue, and diarrhoea.

On examination he seemed to be in fair condition, but was very pale. The mouth was clean; tongue atrophied. Liver not palpable; spleen, two fingers. Nothing to note in the central nervous system except pallor of the optic discs without haemorrhages. He passed one to three stools daily with nothing to note. The Wassermann

reaction was negative. A test meal gave no free HCl. Examination of the blood showed:

Red corpuscles	...	...	...	...	2000000
White corpuscles	...	...	...	...	4100
Haemoglobin	...	...	...	...	42 per cent
Colour index	...	...	...	...	0.95
Differential count—					
Polymorphonuclears	...	...	...	...	25 per cent
Lymphocytes	...	...	...	...	60 "
Large mononuclears	...	...	...	...	3 "
Eosinophiles	...	...	...	...	2 "

There was some anisocytosis and poikilocytosis; granular leucophilia well marked; one normoblast.

*Course.*—He ran an evening temperature of 103°. His liver became palpable. He developed copious early morning stools, very acid, and containing undigested fat. Yeasts, but no or, anisms of protozoal nature were found. There was one attack of bright red rectal haemorrhage. One knee-jerk disappeared, to reappear; his red cells became progressively less in number; megaloblasts and high colour index made their appearance, and he died on November 15th, 1922.

It is quite possible that many would place Case 1 in the category of aplastic anaemia, but this contention need not be disputed, because, however strongly this might be urged, the fact remains that the anaemia was of a primary as opposed to a secondary type. It is not unlikely that the colitis was never of dysenteric origin, since no evidence could be found in his army documents as to the exact cause of the dysentery, but presumably at one time he was diagnosed as suffering from true dysentery by those competent to make the clinical diagnosis.

Case II is of exceptional interest. Manson-Balu<sup>6</sup> says that the anaemia of sprue may approach the pernicious type, with alteration in the size and shape of the erythrocytes and with the appearance of normoblasts, and that it is apparently secondary to the intestinal toxæmia. Bassett-Smith<sup>7</sup> holds that sprue is different from pernicious anaemia in that the colour index is low, and that the anaemia is a true secondary and not a primary one. The anaemia in this instance also would appear to be of the aplastic type.

The autopsy of Case II showed not only the changes usually found in pernicious anaemia but definite ulcers in the large gut, which was in part entirely denuded of mucous membrane, so as to be quite transparent. An enlarged ileocolic gland was seen draining the area of an ulcerated patch in the intestine. This was especially looked for, since these enlarged glands can be felt through the abdominal wall in many cases of chronic dysentery. The gastric mucous membrane was much atrophied, and 1½ inches from the pylorus there was a thickened encapsuled mass in the duodenal wall, projecting into the lumen of the bowel, giving the appearance of an adenoma.

Until some organism or virus can be identified as the specific cause of pernicious anaemia it would not appear unscientific to suggest that the disease may be caused by a combination of circumstances. The importance of achlorhydria can be gauged by the emphasis rightly laid upon this by all authorities. Hunter has placed stress on the co-existent secondary anaemia from oral sepsis and the improvement obtained by dental toilet. The fact that toxins can more easily get into the circulation through an abraded or ulcerated surface than through a normal one lends colour to the part played by the ulceration in two of the cases quoted above, and there is every reason to think that secondary infection can be imposed upon an ulcer in the large bowel, originally dysenteric. The following case illustrates this contention.

S., aged 25, admitted to hospital for dysentery. He gave a history of having had dysentery, caused by Flexner's bacillus, in France in 1917. Had had colitis and attacks of diarrhea with frequent stools containing blood and mucus since that time—the last attack incapacitating him for ten weeks.

Examination showed thickening of gut in both iliac loops, and large tender glands in these regions, more marked on the left. The stools were semi-formed, and contained much bright blood and glairy mucus, and small patches of necrotic tissue lying on the outside of the faeces, and not intimately mixed with them as in the enteritis of malignant malaria. Amoebic cysts were recovered from the mucus. Sigmoidoscopy revealed congested bowel mucosa covered with yellowish-white mucus, and 12 cm. from the anus a small superficial ulcer. A direct swabbing from the ulcer effected, and the stained smear showed six acid fast, pleomorphic, morphologically bovine in type.

These cases are published in the hope that any additional factor, however apparently trivial, brought to light in the investigation of pernicious anaemia may help towards establishing the cause of this disease, be it specific, or consequent

upon a chain of circumstances, the sum-total of which leads to the ultimate production of such an intractable malady.

Either Colonel Cowan or Dr. P. O. Ellison kindly carried out the bacteriological and biochemical investigations referred to in this paper.

## THE ACTION OF HISTAMINE ON THE VEINS:

A METHOD OF DIFFERENTIAL PERFUSION: NITRITES  
IN THE PREVENTION OF HISTAMINE SHOCK.

(Preliminary Communication.)

BY

O. INCHLEY, M.D.

(From the Pharmacological Laboratories, Cambridge and  
King's College, London.)

DALE and LAIDLAW<sup>1</sup> have shown that in histamine shock there is capillary dilatation, with fall in blood pressure and respiratory failure within a very short time of the injection of the drug. They conclude that histamine produces an active dilatation of capillaries, and dismiss the possibility of active constriction of veins. I have devised a method of perfusion which differentiates between the action of a drug on arteries and on veins respectively.

## Method.

Cannulae are inserted into the artery and vein of the organ; bleeding points are ligatured, and the organ after excision is perfused for a short time in the ordinary way with warm oxygenated Ringer's fluid under hydrostatic pressure, in order to wash out the blood and to determine there is no leakage. An incision is made in the organ, avoiding large vessels, or the surface may be scarified. For perfusion of the veins the Ringer's fluid is led to the cannula in the vein and the artery is occluded. The perfusion fluid now passes backwards through the veins and escapes by the incision, and the rate of flow is measured. For arterial perfusion the reverse process is adopted—the vein is occluded and the fluid from the arteries escapes as before. A fresh preparation must be used for arteries and for veins, because after the tissues have been perfused with the drug by the one channel they are so affected that only a small effect may be obtained if perfused afterwards by the other channel.

Certain details of procedure may be briefly indicated for particular organs. For the small intestine cannulae are inserted distally in the portal vein and superior mesenteric artery. The incision in the isolated loop of gut is made longitudinally on the opposite side to the attachment of the mesentery. In the liver a cannula is inserted in the portal vein directed towards the liver; another cannula is placed in the inferior vena cava in the thorax, directed tailwards, and the diaphragmatic veins are ligatured. The liver is then removed after a ligature has occluded the inferior vena cava and hepatic artery in the abdomen. After scarification of the liver separate perfusions of the portal ramifications in the liver and of the hepatic vein may thus be obtained.

For the hind limbs the usual preparation is made, and after skinning the limbs the fascia lata is removed and the superficial fibres of the thigh muscles cut away with scissors. The perfusion fluid exudes from the raw surface thus exposed.

In the lung a cannula is inserted into the pulmonary artery through the right ventricle; another cannula is inserted into the left auricle through the mitral orifice. The remains of the heart are cut away and the lungs with the trachea removed from the body. Into the trachea a small quantity of warm liquid paraffin is introduced, and the lungs are inflated to about their normal volume in the chest and the trachea ligatured. In this way airlocks are made in the bronchi. The surface of the lungs is then scarified to provide exit for the perfusion fluid. The airlocks prevent the lungs from collapsing, and the scarification allows the pulmonary artery and veins to be perfused separately.

By this method of perfusion it was found that after histamine both venules and arterioles were constricted in the isolated limbs and lungs of both cats and rabbits, and constriction of both portal and hepatic veins occurred in the liver of these animals. In the isolated intestine of the cat a similar constriction of venules and arterioles was observed. The rabbit's intestine, however, showed no constriction of mesenteric venules but only the arterial constriction. Ring preparations of the portal vein and mesenteric artery of the pig (from the slaughterhouse) also showed tonic constriction by histamine. It would appear that constriction of venules is an important action of histamine, leading to capillary engorgement and consequent oedema. In view of the above observations the shock induced in the cat, and its absence in the rabbit, would appear to be largely due to the difference in the reaction of the splanchnic veins to histamine in these animals.

These experiments suggested that a preliminary treatment by nitrites in order to dilate the veins, followed by the infusion of a sufficient quantity of Ringer's solution into the veins to fill the dilated vessels, might prevent death in the cat after a toxic dose of histamine.

A cat of 1.9 kilos anaesthetized with urethane received an intravenous injection of 16 mg. of sodium nitrite in 1 per cent. solution; Ringer's solution was then intravenously under 20 cm. water pressure into the vein; 6 mg. of ergamine (B. W. and Co.), containing approximately 2 mg. histamine base, were injected intravenously. The animal did not require artificial respiration, and was alive one and a half hours after the injection of the histamine; the blood pressure and respiration improved considerably within half an hour.

Further experiments on these lines are in progress; a method of treatment after the induction of histamine shock is being attempted.

These experiments suggest that the wheal described by Dale and Laidlaw which arises at the point of local application of histamine may be due to intense local constriction of venules leading to local congestion and consequent oedema. This may be a protective response on the part of the organism to prevent the admission of histamine into the general circulation. If histamine shock be regarded as a generalized extension of such a response it is clear that for treatment the venules must be dilated sufficiently to provide an adequate circulation in the organism, but the oedema must be encouraged in order to assist the elimination of the histamine from the blood.

The regulation of the flow of blood through the veins would appear to be important. Gunn<sup>2</sup> has shown already that veins are constricted by adrenaline.

## A SIMPLE DIET TABLE.

BY

H. S. PEMBERTON, M.B., M.R.C.P.,

ASSISTANT PHYSICIAN, DAVID LEWIS NORTHERN HOSPITAL, LIVERPOOL.

THE following table has been in use in both hospital and private practice for nearly twelve months; the results obtained have been so satisfactory that I venture to think that it may prove of value to others who have to undertake the dietetic management of various metabolic disorders.

Most food analyses are expressed in percentage values of carbohydrates, fats, proteins, water, and salts, the quantity of food itself being given a unitary or workable value. In clinical work, on the other hand, it is obvious that what is required is a unitary value for the specific carbohydrate, fat, or protein content, and with this end in view I was led to devise this simple table. The factors which determine the success and accuracy of any particular diet would appear to be the ease of original construction, an elasticity which allows, if necessary, of a daily change, and a small demand only on the time and intelligence of helpers and patients. This table has been found to meet these requirements, the only other essential being a small pair of scales. The specific contents have been worked out from the excellent tables given by Joslin<sup>1</sup> and Cammidge<sup>2</sup> and from other sources; the quantities are not strictly accurate, as the unit idea was kept mainly in mind, in view of the ordinary conditions under which patients arrange their own dietary. The scheme has been principally used in the dietetic management of chronic nephritis, diabetes mellitus, hyperchlohydria, and achylia gastrica. In these conditions, where specific intolerance of carbohydrates, fats, proteins, or their derivatives is often manifested, a simple control of intake has been obtained by the use of this table; determinations of output or utilization have been made in the case of carbohydrates by glucose estimations in blood and urine, in the case of proteins by determination of urea in the blood and of total nitrogen and urea in the urine, and in the case of fats by the ordinary methods of detecting the onset or degree of acidosis. By these means it has been found that growth or loss of tolerance for carbohydrates and proteins is readily observed and that the onset of acidosis is easily controlled.

The following chart may serve to illustrate the simple method of prescribing food, quantities of which are shown daily; growth of tolerance for carbohydrate (without fasting or the use of "ladder" schemes) and maintenance of nitrogenous equilibrium are also clear. The case is one of a woman of 26 suffering from diabetes mellitus. Blood sugar

was estimated four hours after a meal, and nitrogen intake calculated as 16.5 per cent. of the protein intake; total nitrogen (T.N.) was determined by a modification of the Kjeldahl method.

C = Carbohydrate. F = Fat. P = Protein. Example: On the seventh day on a diet of 1 oz. of carbohydrate and 2 oz. of protein, glucose in urine stood at 6 per cent., in blood at 0.4 per cent., and the nitrogen output in the urine stood at 12.6 grams per diem.

The last section of the diet scale shows the calorie requirement of the particular patient per diem; it is made up according to age, occupation, or severity of disease, and is subject to revision as tolerance varies.

#### Diet Scale.

One ounce of carbohydrate or protein yields 120 calories. One ounce of fat yields 270 calories.

One ounce of carbohydrate is contained in—

- 1½ oz. dry oatmeal (contain 1/3 oz. protein, 1/10 oz. fat).
- 1½ oz. shredded wheat biscuits (contain 1/2 oz. protein).
- 12 Kalari biscuits (Callard).
- 1 pint of milk (contains 2/3 oz. fat, 2/3 oz. protein).
- 1½ pints cream (contain 1 oz. protein, 6 oz. fat; rich cream contain 12 cz. fat).
- 5 oz. potatoes (contain 1/6 oz. protein).
- 5 oz. baked beans (contain 1/3 oz. protein, 1/10 oz. fat).
- 5 oz. boiled rice or macaroni.
- 1½ oz. bread or toast (contain 1/6 oz. protein).
- 10 oz. strawberries, lemons, or oranges.
- 10 oz. Brazl nuts (contain 1½ oz. protein, 7 oz. fat).
- 10 oz. filbert nuts (contain 1 oz. protein, 7 oz. fat).
- 10 oz. carrots or onions.
- 20 oz. grape fruit.
- 20 oz. ripe olives (contain 1/2 oz. protein, 5 oz. fat).
- 6 oz. apples, currants, pears, cherries, grapes.
- 5 cz. plums, bananas, or prunes.
- 20 oz. tomatoes or radishes.
- 20 oz. lettuce (contain 1/2 oz. protein).
- 1 pint beer.
- 1/2 pint stout.
- 1/2 pint port wine.
- Thrice-cooked spinach, celery, or cabbage contains no carbohydrates; the carbohydrate in soy bean or mushrooms is not assimilated.

One ounce of protein is contained in—

- 10 oz. smoked uncooked bacon (contain 6 oz. fat).
- 6 oz. ordinary uncooked bacon (contain 3 oz. fat).
- 5 oz. lean smoked ham (contain 1 cz. fat).
- 5 oz. lean uncooked beef or mutton (contain 1/2 oz. fat).
- 4 oz. roasted lean beef or mutton (contain 1 oz. fat).
- 6½ oz. corned beef (contain 2 oz. fat).
- 5 oz. fresh fowl (contain 1½ oz. fat).
- 5 oz. boiled cod, haddock, sole, or whiting.
- 7 average sardines (contain 1 oz. fat).
- 2 large or 3 small hen's eggs (contain 1 oz. fat).
- 4 oz. cheese (contain 1½ oz. fat) (American, Cheddar, Cheshire).

One ounce of fat is contained in—

- 1½ oz. fresh butter.
- 1 oz. oleo margarine.
- 1 oz. lard, cod-liver oil, olive oil.

One ounce of whisky, brandy, rum, or gin yields 165 calories.

Requirements: Calories per day in the form of—  
oz. carbohydrates.  
oz. proteins.  
oz. fat.

## Memoranda: MEDICAL, SURGICAL, OBSTETRICAL.

### ADENO-CARCINOMA OF THE APPENDIX.

The following report is of interest, as the case is probably the youngest of the kind to be recorded.

A boy, aged 14, was admitted to hospital complaining of abdominal pain, which had come on suddenly the previous night. It was at first referred to the umbilicus, and later to the right iliac region, and was unaccompanied by vomiting or constipation. He had had no similar attacks, and no other important illness. Tuberculosis had occurred in several members of the family (including a sister with peritonitis), but there was no family history of malignant disease.

On admission the temperature was 102.2°, the pulse 108, and the respirations 28. The tongue was furred, and the breath foul. The abdomen moved well with respiration; there was slight distension in the right iliac region, and tenderness over McBurney's point, just below which a cord-like thickening about 2 inches long was palpable. The rectus reflex was less marked on the right than on the left. The examination per rectum was negative.

The patient appeared fairly comfortable, and next morning presented no symptoms, though the tenderness and thickened cord in the right iliac fossa persisted; the tongue was cleaner, the bowels regular, and there was no vomiting. The patient was kept in bed on an ordinary light diet and watched for a week, but beyond an evening rise of temperature to 105°, the daily range being about 1.5°, there were no abnormal signs. A diagnosis of tuberculous appendix was made.

At operation the appendix was found to be 5 inches long, knicked, lying in the "4 o'clock" position, and bound down by adhesions. It showed signs of recent inflammation. On being removed and slit up along the lumen, which was patent, it was found to contain two small faecal concretions at the tip, and in the wall at the point where the kinking occurred were two small yellow masses, very hard, and cutting like an unripe pear.

The report received from Dr. Walker Hall of Bristol on the microscopical examination of the specimen is as follows:

"The condition present is an adeno-carcinoma. There are several small adjacent nodules, each of which represents the same structure. One of them, however, has extended more rapidly than the others, and has reached the peritoneal lymphatics."

The patient made an uneventful recovery, the wound healing by first intention; and when last seen (six weeks after operation) appeared very well. There is a clean, smooth scar, and nothing abnormal palpable per abdomen.

I am indebted to Dr. W. Thompson for permission to publish these notes.

The Hospital, Bridgewater.

A. O'DWYER THOMAS.

### EBONITE POISONING.

In view of the great vogue of amateur "wireless" building and entertaining, the following case may be interesting. So far I have not seen any reports of cases due to work on making "wireless" receiving sets, though it would seem that such cases may shortly become more numerous. The disease referred to is simple ebonite poisoning, and occurred in one of my panel patients a short time ago.

The patient is employed in the room of a factory where the ebonite plates are cut, ground, and lored for holding the parts of amateurs' receiving sets. After a week's work in this room, although he did very little ebonite grinding himself, symptoms of an irritant enteritis occurred—namely, nausea, vomiting, giddiness, headache, diarrhoea, and abdominal cramps. The attack was not very severe and ended the patient left work yielded in a few days to treatment by copious drinks of lemonade, milk, or barley water, stimulants in moderation, and light (milk) diet, with saline aperient thrice daily.

My patient stated that three other men employed in the same room had had similar, but more severe, symptoms, and had had to be absent from work a few days before he himself was attacked. His employers appear to have agreed that the source of the trouble was ebonite dust, as he understood that they had already made arrangements for hoods and suction-ventilating fans to be fixed on the grinding benches. The workers are also encouraged to drink large quantities of milk, and to be scrupulous in washing their hands. These measures, and prevention of eating in workrooms, should prove sufficient to prevent further trouble in these factories.

London, W.

## RUPTURE OF THE SPLEEN.

Rupture of the spleen is not very common, and in public school boys must be a very rare event. The following case is of interest, in that the original injury damaged the spleen, but rupture did not take place till eight days later, following on slight exertion.

A boy, aged 15½, was kneed in the abdomen at football on February 8th. He was able to walk back to the school sick-house, when he vomited freely (dark-brown matter) and became collapsed. There was considerable tenderness in the epigastrium, just to the left of the middle line; his condition steadily improved from hour to hour; there was no blood in the urine or stools, and I came to the conclusion that probably no abdominal organ was injured but that the solar plexus had been affected. Beyond slight epigastric tenderness for a couple of days he had no further symptoms, and was discharged on the evening of February 13th to school with leave off all exercise.

On the morning of February 16th, instead of reporting to me, he played squash rackets after breakfast, and in a few minutes felt acute pain, vomited, and had to be carried into the sick-house in a state of collapse, with acute abdominal pain and slight muscular rigidity on the left side. In consultation with Dr. Lawson Smith we agreed that there was probably some internal haemorrhage; Mr. H. W. Carson came down at once and the patient was operated on within three and a half hours.

*The Operation: Note by Mr. Carson.*

I agreed with Dr. Lempriere and Dr. Lawson Smith that the patient was suffering from internal haemorrhage, and I operated at once, opening the abdomen through the left upper rectus sheath, displacing the muscle inwards. This did not give good exposure, and was supplemented by a transverse incision backwards into the loin from the middle of the vertical incision. There was a quantity of blood and clots in the abdomen. The spleen was found to be torn on its inner surface, but the bleeding was coming from within the hilum. A nodule was felt in the pedicle just at its attachment to the spleen, which may have been a haematoma from the first injury. There was no old blood clot, which confirmed the opinion that internal haemorrhage had not occurred as the result of the first injury. Removal of the spleen was decided upon, but it was made difficult by the shortness of its ligaments. The pedicle, too, was short and contained the tail of the pancreas.

Beyond troublesome post-anæsthetic vomiting (he was two and a half hours on the table) there was no drawback, and he went home to convalesce on March 14th.

A specimen of his blood was sent a fortnight after the injury to Dr. C. H. Andrewes of St. Bartholomew's Hospital, who reported that there were no changes from the normal.

Medical Officer, Haileybury College.

## Reports of Societies.

## RADIOLOGY IN THE DIAGNOSIS OF PULMONARY TUBERCULOSIS.

A MEETING of the Royal Medico-Chirurgical Society of Glasgow was held on April 6th, when a number of communications were made on the diagnosis of pulmonary tuberculosis, with special reference to radiology.

Dr. LEONARD FINDLAY, whose remarks referred particularly to the disease in the young, said that his conclusions were based upon clinical, radiological, and pathological examinations, and that meticulous care had been taken in the matter of diagnosis. He believed that in the period of life before puberty tuberculosis of the lung was a disease of infancy and early childhood, and that it ran an acute or subacute course. In an older child a pulmonary lesion, and especially a chronic pulmonary lesion, should be diagnosed as of a tuberculous nature only with the greatest hesitation and in the presence of the utmost proof. Charts were shown in support of this opinion. Dr. Findlay also pointed out that pulmonary tuberculosis, unless in the very young infant, was seldom, if ever, limited to one lung or one lobe of the lung.

Dr. D. CAMPBELL SUTTIE showed radiograms of cases of pulmonary tuberculosis, and said that admittedly recognizable x-ray appearances had a definite value in the face of negative clinical findings, and negative x-ray appearances had no claim for consideration when clinical signs were undoubtedly present; there were pathological conditions which in their early stage were undetectable by either—for example, miliary tuberculosis. Certain pathological conditions were shown, he said, by radiograms, before clinical signs or symptoms appeared, and also after clinical signs and

symptoms had disappeared. Certain pathological conditions, on the other hand, were detected by the clinician before x-ray appearances were present.

Dr. A. S. M. MACGREGOR introduced the subject from the public health point of view, and referred to the work done by Drs. Wilson, Henderson, and himself in correlating clinical and radiological features in special groups of cases. Some of the earlier ideas as to the nature of apparent abnormalities in radiograms had had to be discarded, and he pointed out that radiographic appearances varied within wide limits in normal chests. In regard to the routine diagnosis of lung conditions, perhaps the most important aspect of radiology was the aid it gave in a negative sense in doubtful cases; in this respect the right apex was a constant stumbling-block. Radiology was also of value in many cases of chronic bronchitis where the symptoms suggested a coexistent tuberculosis. X rays often detected hidden, unsuspected, and otherwise undiagnosable lesions.

Dr. J. A. WILSON said that if the cases notified as pulmonary tuberculosis in a district of Glasgow were analysed it would be found that the error in diagnosis, in the best year, was about 33 per cent. For the past three years efforts had been made to evolve a scheme to deal with the increasing number of notifications of cases which were doubtfully tuberculous. While it was too early to dogmatize, the conclusions arrived at, as a result of the combination of careful x-ray and clinical work, were that (1) cases of tuberculosis of the lung had a definite radiological picture; (2) hilus tuberculosis was an uncommon disease; (3) basal lesions were, as a rule, non-tuberculous, the exceptions being those secondary to a chronic tuberculous infection of the abdomen; (4) there might be physical signs of moderately extensive infection of the respiratory tract with no radiological counterpart—such infections were non-tuberculous.

Dr. FERGUS L. HENDERSON gave a demonstration of radiograms illustrating points in diagnosis.

## PROLAPSE OF THE UTERUS.

At a meeting of the Aberdeen Medico-Chirurgical Society held on April 5th, with the President, Dr. ALEXANDER OGSTON, in the chair, a lantern demonstration on pelvic hernia (prolapse of the uterus) was given by Mr. ALEXANDER and Mr. VICTOR DON. The anatomy of the pelvic floor was demonstrated, and the authors pointed out that the real support was formed by the levators, coccygei, etc., and their coverings, the true fascia of the muscles. Sections of the pelvis showed the sub-peritoneal tissues impregnated with fat, with no definite ligamentous bands. The physiology affecting the abdomino-pelvic pressure was explained, showing that gravity had little to do with prolapse, or the so-called ligaments with retention of organs, the onus being entirely on the pelvic muscles and their fascial coverings. A new operation, founded on the methods which had proved successful in dealing with herniae elsewhere, was demonstrated, the edges of the levators being brought together and their fascial coverings overlapped, or, if these were found much scarred or thinned, a piece of fascia lata from the thigh was introduced to strengthen the support. Operations which depended on the suturing of connective tissues only were condemned as unreliable. The authors said that they had not yet had sufficient experience of the results, but the operation was stated to be comparatively simple and safe, and healing was ensured by gentle handling of the tissues. The demonstration was followed by a discussion.

A MEETING of the London Association of the Medical Women's Federation was held at the Elizabeth Garrett Anderson Hospital on April 10th, with Dr. LOUISA MARTINDALE in the chair. Miss IDA C. MANN read a paper on some congenital defects of the eye and their confusion with acquired conditions. She described many congenital defects of the fundus, of the iris, the cornea, and the lids, but confined her attention to those defects which had to be diagnosed from acquired pathological conditions presenting very similar appearances. Her paper was illustrated by a series of drawings in colour. Miss ROSA FORD read a paper on a case of intracranial tumour, diagnosed by the visual defects produced. The diagnosis both of the presence and the site of the tumour in this case rested mainly on the detection of an increasing contraction of the visual fields, especially with regard to colour vision, and associated with papilloedema. The tumour was located in the occipital region. Mr. Percy Sargent operated on the case at the National Hospital, Queen Square, and successfully removed an endo-thelioma from the occipital lobe.

## Reviews.

### THE PHYSIOLOGY OF REPRODUCTION.

CONSIDERING the very common and not unnatural curiosity which exists in regard to questions relating to reproduction, it is remarkable that so few books have been devoted to the subject by human physiologists. Probably no class of medical practitioner gets less encouragement to seek for information in physiological textbooks than the obstetrician or gynaecologist. In the ordinary textbooks of physiology the subjects in which he is particularly interested are usually dismissed in one or two chapters dealing in a superficial way with the male and female reproductive organs; for anything like a full description of the functions of these organs he is thrown back upon textbooks of midwifery or gynaecology. It is not sufficient explanation of this curious lack that few if any individual physiologists are in a position to write a textbook on reproduction. It is indeed true that the author of such a book has to be a biologist, a biochemist, an embryologist, a histologist, and in some degree an agriculturist and even a veterinarian. With great advantage he might also be an obstetrician and a gynaecologist. But we have known physiologists tackle problems and write books upon subjects in which as wide and varied a range of knowledge was really required for complete mastery of the subject.

It is now thirteen years since Dr. F. H. A. MARSHALL'S *The Physiology of Reproduction* appeared to remove in some measure this reproach from physiology and to fill in very large measure the gap in our scientific literature to which we have just referred. For some years the first edition has been out of print and many readers will be glad to know that a second edition has been produced.<sup>1</sup> Dr. Marshall does not profess to be in *propria persona* the scientific Proteus we have just described as the ideal editor of such a textbook, but he has, as the next best thing, elicited the help of various specialists, and has himself presided over the editing of their contributions. Thus Dr. William Cramer has again contributed the sections upon the biochemistry of the sexual organs, a subject on which he has made himself a recognized authority, and he has also revised the section on changes in the maternal organism during pregnancy originally written for the first edition by Dr. James Lochhead. Dr. Lochhead's other contribution to the first edition, the chapter on foetal nutrition and the physiology of the placenta, has been reprinted practically as it stood; only slight additions, chiefly in the form of footnotes, for which Dr. Marshall is responsible, have been made. It is to be regretted that Dr. Lochhead's duties at Gibraltar have prevented his revising his earlier work, and in our opinion the book suffers in some degree from the lack of adequate revision of these chapters. Several omissions occur which it is unnecessary to specify in detail, but we may mention the work carried out by Slemons and his colleagues in the Johns Hopkins Hospital and embodied in his oration at Toronto in 1919. Dr. Cresswell Shearer has written in this edition a most excellent chapter on fertilization, in which he includes a description of the oxidation processes occurring in the egg on and after fertilization. He also gives a short but lucid account of Child's brilliant, suggestive, and far-reaching work on the life cycle. For the remaining chapters Dr. Marshall is himself responsible.

This edition undoubtedly maintains the high reputation acquired by its predecessor, and the book taken as a whole remains the most comprehensive and authoritative treatise on the general aspects of the subject in the English language. Particularly is this the case with regard to all questions of "comparative" and of what is sometimes called "pure" as opposed to "applied" physiology. The value of the book would, however, be enhanced by a more consistent endeavour to link up these "purely" physiological matters with the practical and clinical considerations associated with obstetrics and gynaecology in the human subject. This might have been done by associating an obstetrician and gynaecologist in the preparation of the book. None of the medical contributors to the present edition would appear to have the special experience of the processes of reproduction in the human subject which in its normal and in its abnormal aspects falls to the lot of an obstetrical and gynaecological specialist, and the

result is that the sections dealing with the human subject lack the ring of authority and personal knowledge which characterizes the rest of the writing. There are also omissions, and in some instances the quotations from obstetric textbooks are either out of date or imperfectly assimilated. We note, for example, that some important work on the cause of menstruation by various gynaecologists receives scant if any attention. Menstruation is to a great extent—indeed to a possibly disproportionate extent—regarded from the standpoint of comparative physiology. There is little or no reference to much of the later work embodied in Novak's recent monograph. The same criticism applies also to the discussion of the question as to the time relationship between ovulation and menstruation. It is quite true that observations on the human subject are not so easy to make or to control as similar observations on the lower animals, but their importance is, *ceteris paribus*, much greater. That obscure subject, the cause of the onset of labour, is rather briefly dismissed, and the view that it is due to a stimulus arising in the pituitary gland is not considered. The section on prolonged gestation hardly seems adequate from the point of view either of veterinary experience or of the observations of obstetricians. That most interesting question, the determination of sex, is, however, very fully and most excellently discussed, and all the latest work on the subject has been summarized. The section upon sterility in females is disappointing, and once again shows the need of collaboration with someone who is familiar with gynaecological literature.

Such disappointment as the above criticisms indicate is really a compliment, even though rather "back-handed," to Dr. Marshall's book. Its great merits stimulate our expectations to a perhaps unreasonable extent. We would, however, earnestly commend to Dr. Marshall the project of elaborating the book along the lines suggested, and so making it in future editions even more the veritable authoritative and comprehensive work which it already very nearly is. Such a treatise as we contemplate might attain double the size of the present volume, but its value would be more than doubled to medical scientists, and it would form an even more noble contribution to British scientific literature than the volume under review.

### THE PREPARATION OF PATIENTS FOR OPERATION.

THERE are several good books on the after-treatment of operation cases, but it has occurred to Dr. CHARLES LEBEYRE of Toulouse to write a volume<sup>2</sup> on the treatment of patients in the period whilst they are awaiting operation. Such a book would seem to fill an unoccupied niche in medical literature, but the successful accomplishment of the task is much more difficult than at first appears. The general preparation of patients is to-day more or less standardized, and for special operations, or rather for operations on special organs, surgeons are already in the habit of attending to certain points in order to have their patients in the best possible condition. This is seen to best advantage perhaps in urological cases, and particularly in operations upon the prostate, where within the last few years very great progress has been made and results certainly improved. Every operator is further aware of the advantages of attention to the mouth in abdominal cases, and no one will deny that gastric lavage and the giving of fluids by other channels than by the mouth have a beneficial effect upon dehydrated sufferers from pyloric stenosis. Recently the Mayo have demonstrated the value of the pre-operative estimations of hepatic function and of blood-coagulation time in chronic biliary stasis, and attempts have been made in Harvey Cushing's clinic to reduce intracranial tension in tumour cases by giving hypertonic solution intravenously or by the mouth. All of these straws (if we may attach to which way the wind is blowing. Surgeons most assuredly are taking infinitely more pains to ensure the success of their operations. The enucleation of a prostate or the removal of a stone from the common duct is no longer the *tour de force* that once it was, sufficient in itself and awe-inspiring in the beholder. To-day we demand, and not unreasonably, a living patient at the end of it all.

It is to further this excellent tendency that Dr. Lebevre has written his little book. It is prefaced by an extract from

<sup>1</sup> *The Physiology of Reproduction*. By Francis H. A. Marshall, Sc.D. Camb., D.Sc. Edin., F.R.S. Second and revised edition. London and New York: Longmans, Green, and Co. 1922. (Roy. 8vo, pp. 770; 182 figures. 36s. net.)

<sup>2</sup> *La Période Pré-opératoire*. By Charles Lebevre, Chief of the Surgical Clinic of the Faculty of Toulouse. Paris: A. Maloine et Fils. 1922. (Post 8vo, pp. 260; 2 figures. Fr. 10.)

J. L. Faure which is worth quotation because it shows also a modern revival, and that is the declaration of reverence with which many surgeons regard their work. This attitude was once, we think, rather the right of the physician, and the passing of it to the surgeon as well is not something more lost by the former to the latter, but something which medicine as a whole must welcome and in which it must rejoice. Faure says:

"And surgery to-day is truly the *res sacra* of ancient times, the sacred thing which one must approach with fear and speak of with respect as a goddess who holds in her sovereign hand the life and death of those who sacrifice at her altar."

The scope of Dr. Lefebvre's book is wide and would have been better had he confined himself to fewer subjects. A series of more or less disjointed chapters or essays would better have fulfilled his purpose. We find ourselves but little interested in general dissertations on the preparation of tuberculous, syphilitic, malarial, and gony patients, and of drug takers. And yet these subjects are not without their interest, so that perhaps our lack of sympathy is the fault of the author. An interesting section is furnished on diabetics as possible subjects for operation, and we are glad to see that obesity receives attention. There is no doubt whatever that the obese patient is anything but a first-class operative risk, and most surgeons of experience have learned to regard him with considerable apprehension. The author has some sane suggestions to make on the improvement in the general hygiene of this class. The dangers of subsequent fat embolism might have received more attention. Nor has the author referred to the special studies of which we have made mention above.

In one thing we can whole-heartedly agree with Dr. Lefebvre, and that is his condemnation of pre-operative purgation. He quotes again the excellent J. L. Faure, and we will transcribe the extract in full:

"For a very long time I did what I had always seen my masters do, and I purged my patients conscientiously on the eve of operation. Then I asked myself why we purged them thus, and I thought that it was without doubt because our masters purged them. I also thought that if our masters purged them it was because they had seen their masters do it. So that finally I arrived at this conclusion, that if to-day we purge our patients on the eve of operation it is really because Dupuytren purged them."

Some three years ago the question was discussed in a leading article in this JOURNAL (1919, vol. ii, p. 570), and recently the opinions of a number of surgeons were collected in a short article published in our issue of March 17th (p. 476).

#### URETHROSCOPY.

*The Urethra and the Urethroscope*,<sup>3</sup> by Dr. F. CARMINOW DOBLE, gives an account not only of the various models of urethroscopes in use, but also of their method of employment. The author asserts that although many textbooks on the subject of venereal disease, and of gonorrhoea in particular, have appeared within recent years, but scant attention has been paid in them to the subject of urethroscopy. His book is intended to be used as an adjunct to general textbooks of treatment, and its aim is to be, above all things, a thoroughly practical guide to urethroscopy. With the opening of large numbers of venereal clinics throughout the country many medical men who have perhaps no previous knowledge of urethroscopy find themselves in the position of having to diagnose and treat urethral conditions. Although a practical demonstration must always be a better method of education than that afforded by textbooks and manuals, it is not always possible for those who wish to learn the rudiments of urethroscopy to visit clinics where urethroscopy is habitually carried out.

The book is divided into three parts: the first deals with anterior urethroscopes and the examination of the anterior urethra, the second with posterior urethroscopes and posterior urethroscopy, and the third with the examination of the female urethra. All the principal urethroscopes of British manufacture are included, as well as a few of the better known Continental models. The descriptions are made more easy of comprehension by excellent plates, and the good points and deficiencies of each type of urethroscope are noted in turn. Dr. Doble would appear to have used all these instruments, but he does not state his personal preference.

<sup>3</sup> *The Urethra and the Urethroscope*. By F. Carminow Doble, M.R.C.S., L.R.C.P. Lond. Oxford Medical Publications. London: H. Frowde, and Hodder and Stoughton. 1923. (Demy 8vo, pp. x + 120; 45 figures. 6s. 6d. net.)

He has himself been responsible for an addition to the Holborn Surgical Instrument Company's anterior urethroscope, which allows of it to be used for posterior urethroscopy. In spite of the absence of water dilatation, Dr. Doble has found that this instrument gives him a very satisfactory view of the posterior urethra. The commoner pathological conditions of both the anterior and the posterior urethra are described as tersely as possible, as are also the procedures best calculated to remedy them. Although anyone who reads Dr. Doble's book must agree with most of what he writes, some will wonder whether urethroscopic methods of treatment are as important or as successful in the cure of gonorrhoea as he would lead us to believe. However, even although these doubts may obtrude themselves on the attention of the reader, he will in the end be forced to admit that no one can pretend to treat gonorrhoea successfully unless he has made himself an expert in urethroscopy. Even if intraurethrosopic surgery be limited in its scope, there can be no doubt that the urethroscope, regarded solely as a means of deciding what measures shall be adopted, is a therapeutic weapon of the very greatest importance. To those who wish a complete, practical, and on the whole an unbiased explanation of the subject, we recommend his book.

#### GREEK BIOLOGY AND MEDICINE.

Dr. H. O. TAYLOR's pleasantly written book, *Greek Biology and Medicine*,<sup>4</sup> which forms the third volume in the American Library of *Our Debt to Greece and Rome*, though intended for laymen and not professing to compete with more elaborate works on this subject, will yet be read with advantage by most medical men. It shows how the scientific spirit of Greek biology and medicine still influences modern intellectual activity, and that it is the method rather than the substance of Greek science that constitutes our debt. In an interesting chapter entitled "The Hippocratics" the principles rather than the details of the Father of Medicine's practice are described, and it is said that ethically the most influential document in the history of medicine is the famous Hippocratic oath. The most notable hypotheses of the Hippocratics were the four humours, the natural origin of disease, and the *vis medicatrix naturae*. A certain amount of hypothesis entered into the Hippocratic art of healing, as it necessarily does into every art and science, but Hippocrates was sparing in hypotheses, as few men after him were, and always introduced them with extreme conscientiousness.

In the account of Aristotle's biology this greatest of Greek biologists, and almost the greatest of Greek philosophers, is described as not only a pioneer of natural science but as correlating the processes of nature with the *how* and the *why* of living things.

In the chapter on the progress in anatomy and medicine the Alexandrian school and the influence of Herophilus and of Erasistratus are sketched. This is followed by a critical and specially attractive account of the final development of Greek medicine and biology by Galen, whose work was a constructive synthesis amalgamating the Hippocratic and Aristotelian traditions with his own observations. In the final chapter the linkage with modern medicine is considered; the influence of Aristotle on Harvey is discussed, and it is seen how Sydenham turned away from the chemical and mechanical hypotheses of disease to follow the principle of independent observation set up by Hippocrates. Both in name and matter this book recalls the recent publications of Dr. Charles Singer, to whom Dr. Taylor makes full acknowledgement.

#### PNEUMOCOCCIC INFECTIONS.

*Les Pneumocoques et affections pneumococques*,<sup>5</sup> a monograph from the Pasteur Institute, Drs. COTONI, TRUCHE, and Mlle RAPHAËL give a comprehensive account of the pneumococcus, its bacteriology and serology, the infections it produces, and their specific treatment. The volume contains the results of much original work begun as long ago as 1908 under the supervision of Professor Maurice Nicolle, to whom this monograph is dedicated; but it contains also full references to the

<sup>4</sup> *Greek Biology and Medicine*. By Henry Osborn Taylor. *Our Debt to Greece and Rome*. Editors, G. D. Hadzits, Ph.D., and D. M. Robinson, Ph.D., LL.D. London, Ca'cutta, Sydney: George G. Harrap and Co., Ltd. 1923. (Cr. 8vo, pp. xv + 151. 5s. net.)

<sup>5</sup> *Pneumococci*. By Par L. Coton, C. Truche et Mlle A. Ra. Pasteur. Paris: Mas-on et Cie. 1922. temperature charts. Fr. 14.)

researches of other workers, such as Douchez, Avery, R. Cole, Theobald Smith, Washbourn, and F. S. Lister, and there is a useful bibliography with 270 entries. The relation of the enterococcus and the *Streptococcus mucosus capsulatus* to the pneumococcus group is discussed, and the groups of pneumococci are described, the classification made by Nicolle and Dubains being adopted. The preparation and properties of antipneumococcic serum are considered, and contrary to the views of the American workers the authors do not insist on the use of a typed serum, but prefer a serum possessing the most active powers against the pneumococcus. Intravenous injection is preferred to the hypodermic administration of the serum.

The crisis in pneumonia is fully dealt with, both from its clinical side and from the interesting point of view of its mechanism. The clinical features are thus correlated with the changes that are taking place in the blood. The exacerbation of the symptoms immediately before the crisis coincides with a maximum accumulation of pneumococcic poison, and in response to this emergency the body discharges into the blood lytic antibodies which attack the albuminous pneumococcic poisons, thus causing a secondary intoxication, so that the crisis is regarded as a phenomenon of hypersensitiveness. As a result of this anaphylactic reaction great vaso dilatation of the intestinal and peripheral vessels and fall of blood pressure, leucopenia sweating, diarrhoea, and polyuria follow. The return of chlorides to the urine may be explained by their previous fixation to the pneumococcic toxins. Although the presence of pneumococci in the blood makes the prognosis worse—and here it is noted how much more often blood cultures are positive in blacks than in whites—there is, it is held, no real pneumococcic septicaemia in these cases, for the pneumococci are merely on their way to set up potential metastases. The section on preventive vaccination contains many statistics from the war experience. This valuable monograph concludes with a short account of chemotherapy in which the danger that optochin may cause amblyopia is mentioned.

#### A FRENCH TEXTBOOK OF MEDICINE.

THE title of Dr. JOURNÉ's book, *Précis de Pathologie Médicale*,<sup>6</sup> is, for the English reader at any rate, doubly misleading. It suggests in the first place that the book is a small one, whereas in reality it contains over 1,200 closely printed pages, uninterrupted by either illustrations or diagrams; and in the second place it gives the impression that the book deals mainly with pathology, which it does not. It deals with medicine; it is a textbook of medicine, and would far more suitably be called so. In aim, outline, and general treatment it resembles the usual standard works, differing from them, however, in being rather more comprehensive in some ways—for example, in the inclusion of mental diseases—and rather less so in others, omitting for the most part the references to the history of disease, and spending less space on treatment. It contains an immense amount of information, mostly of a highly exact nature. It is true that some statements are rather dogmatic, such as those dealing with d'Herelle's bacteriophage, the pathology of cerebrospinal fever, and the therapeutic value of antitetanic serum; others are not sufficiently comprehensive, as in Dr. Journé's omission of Flexner's bacillus from the etiology of bacillary dysentery, and in the somewhat inexact account of the life history of *Bilharzia haematobium*. But, on the whole, there is very little to which exception can be taken. On some subjects it is remarkably good; functional diseases of the kidneys, Vidal's work on haemoclasia, colloidoclasia, hepatic insufficiency, herpes, and kindred conditions to which the French have recently been devoting themselves are well summarized.

The book has, in fact, a very distinct French stamp upon it, and it is partly for this reason that it is so attractive. To the post-graduate, to the aspirant to higher medical degrees, and to the young consulting physician, we would highly recommend it, and shall be surprised if its clear, terse sentences, its fascinating descriptions, and its wealth of information do not appeal to all who wish to step aside from the older and more weather-beaten volumes of their own country.

<sup>6</sup> *Précis de Pathologie Médicale*. By M. Journé. Paris: A. Maloine et Fils. 1923. (Imp. 16mo. pp. 1269. Fr. 25.)

#### CARRIERS.

ALTHOUGH there is considerable difference of opinion as to the importance of "carriers" in spreading disease, no one will deny the need for further inquiry and research in this work of transmission. In *Carriers in Infectious Diseases* Dr. HENRY J. NICHOLS renders great assistance in such an inquiry. He defines a carrier as an individual who harbours and transmits pathogenic parasites without showing the usual evidences of infection, and he classifies carriers as true carriers, where the parasites are pathogenic and virulent; pseudo-carriers, where they are non-pathogenic and non-virulent; and possible carriers, which include those cases in which the organisms are of uncertain significance. On the treatment of carriers Dr. Nichols has not much to say that is new. The chronic diphtheria carrier is the despair of the public health officer, especially where there are no facilities for obtaining a virulence test; patients are frequently kept in hospital or otherwise isolated for very many weeks because successive cultivations of material taken from throat or nose reveal the presence of diphtheria bacilli. When the throat is affected removal of the tonsils is recommended, but no definite advice is given with regard to nasal carriers. For the treatment of persistent typhoid or cholera carriers surgical interference is suggested, though it is known that it does not invariably meet with the success which might be expected. A plea is put forward for an organized search for carriers. Contacts with known cases of disease, as well as those persons known as food handlers, should, in the author's opinion, as a routine measure be subjected to examination which would include a search for diphtheria bacilli from the throat and nose, haemolytic streptococci from the tonsil, meningococci from the nasopharynx, pneumococci from the saliva, typhoid bacilli from the faeces and urine, and the organisms of cholera and dysentery from the faeces.

The value of the book is increased by the inclusion of a section on carriers in veterinary medicine by Captain R. A. Kelsor of the Veterinary Corps, U.S. Army. He divides animal carriers into three groups. The first includes carriers of organisms which are pathogenic for man as well as for the lower animals; the second deals with carriers of organisms which are pathogenic for lower animals and may possibly prove pathogenic for man under certain circumstances; and the third group includes carriers of organisms pathogenic for animals only.

Although no new ground has been opened by the authors of this volume they have succeeded in giving a clear exposition of the carrier question as it is known at present.

#### NOTES ON BOOKS.

WHEN the war broke out in 1914 the Division of Economics and History of the Carnegie Endowment for International Peace turned its attention to the economic problems of war. Incidental studies and surveys of portions of the field were made, but during hostilities it was, for obvious reasons, impossible to undertake the general history. By the summer of 1919, however, the Endowment was able to take up the plan for an economic and social history of the world war. One of the first steps was to set up an editorial board in each of the larger countries and nominate special editors in the smaller ones. After weighing various proposals a series of monographs was projected, consisting for the most part of unofficial yet authoritative statements, descriptive or historical, "about halfway between memoirs and blue books," besides these a number of studies by specialists are in preparation dealing with technical or limited subjects, historical or statistical. Among the British series of volumes already issued is the *Bibliographical Survey of Contemporary Sources*, compiled by Miss M. E. BULLOCK. This large and well produced book of 650 double columned pages is put forward as a tentative survey of British literature dealing with the economic and social history of the United Kingdom during the war and reconstruction periods. The list is primarily one of Government publications. In addition some thirty or forty periodicals (including the two principal

<sup>7</sup> *Carriers in Infectious Diseases: A Manual on the Importance of Pathology, Diagnosis, and Treatment of Human Carriers*. By Henry J. Nichols, M.D., M.A., Major Medical Corps, U.S. Army. With a section on Carriers in Veterinary Medicine, by R. A. Kelsor, D.V.M., Major Medical Corps, U.S. Army. Baltimore: Williams and Wilkins Co. 1922. (Med 8vo. pp. 181; 11 illus. 350 pages.)  
<sup>8</sup> *Bibliographical Survey of Contemporary Sources for the Economic and Social History of the War*. By M. E. Bullock, B.A., D.Litt. Clarendon Press: London and New York: Humphreys, Blot & Co. (Roy. 8vo. pp. xix + 658. Price not stated.)

medical journals) were consulted in order that important articles bearing upon the subject might be noted. Students of sociology and economics will no doubt find this compilation valuable for reference.

*The Principles and Practice of X-ray Technic for Diagnosis*<sup>9</sup> is the title of a book compiled by Dr. JOHN A. METZGER of Los Angeles, as a guide to students and operators in obtaining good x-ray results. There is a short chapter on apparatus, tubes, and the x-ray laboratory, but the main part of the book deals with the standardized positions for the radiography of the various parts of the human body. Each part is dealt with separately, and a photographic illustration shows the patient, tube, and plate in the position the author recommends as giving the best result. Then, after explanatory notes, a short paragraph gives the exact details of diaphragm, filter, distance, milliamperage, spark-gap, exposure, etc., with an interrupterless transformer and a Coolidge tube. It should, however, be noted that all the positions are equally applicable to the use of coil and gas tubes. The chapters on stereoscopy and localization are short and do not go much into detail. The Sweet-Brown method for the localization of foreign bodies in the eye is sufficiently described and illustrated. There is a useful chapter on dental and oral radiography in which again numerous illustrations add to the value of the text. The final chapter is on the developing room appliances and the technique of development, in which all the most important points are stated. There is not much, if anything, which is new in this book, but students of radiology and those who have not much experience or expert knowledge should find it useful.

Under the title of *Medizinisches Vademecum*<sup>10</sup> Miss B. LEWIS, who is a teacher of medical German in Vienna, has edited a series of handbooks in German and English, of which we have received volumes dealing respectively with *Otology*, *Rhino-Laryngology*, and *Ophthalmology*. Each book has first a number of clinical lectures by various Viennese authorities on the different subjects, then a number of anatomical illustrations, followed by verbatim reports of clinical examinations of patients and directions during operations, with lists of instruments, etc., printed in German and in English on facing pages. The volumes we have seen are calculated to be very useful to British medical practitioners who may desire to visit the special clinics in German-speaking countries, by giving them a large vocabulary of modern German medical terms.

The important book on *Orthopedic Surgery*, by Sir Robert Jones of Liverpool and Professor Robert W. Lovett of Harvard, reviewed in our columns last week (p. 634), has now been issued in London as an Oxford Medical Publication by Henry Frowde and Hodder and Stoughton, price 42s. net.

<sup>9</sup> *The Principles and Practice of X-ray Technic for Diagnosis*. By John A. Metzger, M.D. London: Henry Kimpton. 1922. (Roy. 8vo, pp. 141; 61 figures. 14s. net.)

<sup>10</sup> *Medizinisches Vademecum in deutscher und englischer Sprache*. Von B. Lewis. I. Für Ohrenärzte (pp. xiv + 205); II. Für Nasen- und Halsärzte (pp. viii + 215); III. Für Augenärzte (pp. viii + 247). London: H. K. Lewis and Co., Ltd.; Vienna: B. Lewis. 1922. (Med. 8vo, illustrated. 12s. 6d. each volume.)

## MEDICAL AND SURGICAL APPLIANCES.

### *Pedicle Forceps for Nephrectomy.*

MR. HENRY WADE, C.M.G., D.S.O. (Edinburgh), writes: The pedicle forceps for nephrectomy made for me by Messrs. Down Bros., Ltd., of London were designed to provide a powerful crushing

haemostat which could be conveniently applied to the blood vessels of the renal pedicle and simplify the subsequent ligation of them. The blades are powerful, broad, and serrated, and have on their convexity a notch which facilitates transfixing the pedicle without the risk of having haemorrhage from puncturing a vessel. The blades are curved, which renders easier the passage of the loop of the ligature over the point when it is being tightened. I have found them a convenient and useful instrument.

## HOSPITAL PROVISION FOR DISABLED WAR VETERANS.

### AN AMERICAN REPORT.

ON October 6th, 1917, Congress by Amendment to Public Act 193 of September 2nd, 1914, provided for the "hospitalization" of disabled veterans of the war into which the United States of America had recently entered. The amendment provided that the United States should furnish the injured person with

"such reasonable services and with and similar app useful and reasonably necessary." l, and hospital limbs, trusses, etermine to be

### *Congress and the Care of Ex-Service Men.*

In March, 1919, Public Act 326 authorized the Secretary of the Treasury to provide immediate additional hospital and sanatorium facilities for the care and treatment of certain persons employed at sea and in various Government services in addition to soldiers and sailors, thus augmenting the provision at the disposal of the United States Public Health Service. The method employed by Congress to meet this particular hospital problem was through lump-sum appropriations to the Public Health Service, providing for the maintenance of patients in existing institutions, and the maintenance of Public Health institutions themselves. Much of this expenditure was economically unsound because it provided expensive and unsatisfactory facilities of no permanent value. In June, 1920, the maintenance appropriation for the care of disabled men was transferred from the Public Health Service to the Bureau of War Risk Insurance, and thereby it became possible for the latter body to utilize other facilities for the maintenance of beds in addition to those of the Public Health Service. But these facilities were still inadequate, and on March 4th, 1921, Public Act 384 was passed "providing additional hospital facilities for patients of the Bureau of War Risk Insurance and of the Federal Board for Vocational Education, Division of Rehabilitation, and for other purposes."

### *Appointment of Expert Advisers.*

The duty of carrying out the provisions of this Act devolved on the new Secretary of the Treasury, the Hon. A. W. Mellon, who appointed a small advisory board of Consultants on Hospitalization; and it is from their report, which has just been issued,\* that we have summarized the early history of hospital provision for ex-service men in the United States.

The consultants appointed were Dr. William Charles White, formerly professor of neuro-pathology, and now medical director of the Tuberculosis League Hospital in Pittsburgh, Pa.; Dr. Frank Billings, dean of the faculty of Rush Medical College; Dr. John E. Bowman, Chancellor of the University of Pittsburgh; and Dr. Pearce Bailey, the neurologist, now deceased, who resigned after three months' service, and was succeeded by Dr. George H. Kirby, director of the New York Psychiatric Institute at Ward's Island, N.Y.

The consultants met for the first time on March 16th, 1921, obtained the assistance of an advisory committee under the chairmanship of Dr. T. W. Salmon (who represented the National Committee for Mental Hygiene), and proceeded to assemble data on which to build a Federal programme for "hospitalization." For this purpose an enormous amount of evidence appears to have been taken, and analyses were made of data concerning population, number of draftees, physical examinations by the army authorities, number of patients in the hospitals, prospective number to be hospitalized, their distribution by district, sex, colour and nationality, available facilities for treatment, percentages of empty beds, railroad facilities, climate, distribution of population, and so forth.

### *Problems before the Consultants Board.*

The first great difficulty met with by the Board of Consultants was the division of authority in dealing with the veterans, and they felt that a centralization of authority would materially assist in establishing a "broad Federal hospital program." Three different bureaux of the Government dealt with the care of the veteran—the Bureau of War Risk Insurance, the Public Health Service, and the Federal

\* Report of the Consultants on Hospitalization appointed by the Secretary of the Treasury. Washington: Government Printing Office. 1923. Pp. 112.

Board for Vocational Education—together with a large number of accessory organizations and private institutions.

Recognizing the desirability of a centralization of authority and decentralization in districts, the consultants submitted their views to the Secretary of the Treasury, who adopted their proposals to the extent of transferring to the Bureau of War Risk Insurance those functions of the United States Public Health Service which had to do with the care of ex-service men, and could be legally transferred.

In analysing the data for the purpose of establishing fundamental principles the consultants were faced by several secondary problems. Thus they found that there were large numbers of men in hospitals whose final recovery would be attained more quickly outside institutions. This was especially the case with psychoneurotics of the neurasthenic type, to the majority of whom hospital treatment was probably detrimental. The opinion of the consultants was that these patients should receive treatment in out-patient clinics, having a uniform policy of treatment under central control, the staffs being under divisional directors, and these directors under supervision from the central office at Washington. They pointed out also that patients should be made to realize that psychoneurosis is not a permanent disability, and that therefore permanent compensation was not to be granted.

Then the consultants found that the liberal provision by the Government for the care of ex-service men had led to a more pronounced influx into hospital during a period of great depression in trade than would otherwise have happened. Further difficulties arose in connexion with the personnel of the hospitals. In general, the consultants found that the civil institutions were much more economical in their administration than the Government institutions. They noted also the absurdity of trying to standardize personnel in institutions differing so widely in the requirements of the patients as a tuberculosis sanatorium and a surgical hospital; and they could see no reason in the demand of the Veterans' Bureau that all personnel should be housed on the property of the hospital. The consultants deprecated the tendency in Government institutions to centralize in the matter of special medical services, and to refuse the assistance of expert consulting advice from civil teaching institutions. In questions such as these the consultants found great difficulty because of the variation of expert opinion; but they felt that "in fields of human activity where positive knowledge is not available no standard could be set, and any attempt to standardize human organization could only meet with failure."

#### Standard Hospital Buildings.

The only field in which standardization was accomplished was in hospital planning; and to the Report is appended a series of ground plans and views of hospitals erected in various parts of the United States. Standardization was one of the chief means of securing the rapid construction of these institutions. Difficulties with regard to the negro population were met by the location of an institution in a centre of negro education, conducted under negro leadership.

In considering the future economic use of the institutions to be erected, the Board of Consultants had the experience and co-operation of the National Home for Disabled Volunteer Soldiers. This body deals with the domiciliary care of chronic cases which remain from the Civil War—ex-service men for whom medical care is not the most important factor. Bearing in mind that many such cases will exist in the future, the consultants advised that such institutions for hospitalization as that at Chelsea, N.Y., should in time develop into homes for disabled ex-service men.

Notwithstanding the cumbersome nature of the machinery for co-operation between State and Federal Government, a beginning was made in hospital construction within five weeks of the appointment of the consultants, and in a little over three months plans were ready for 2,500 beds at a cost of 5,285,000 dollars, the consultants advising on the location and type of the hospitals which were to be erected. At this point, however, delays occurred owing to the establishment of the United States Veterans' Bureau and to changes in administration. The Veterans' Bureau was established in August, 1921, and in November a Federal Board of Hospitalization was instituted. Very early there seems to have been some disagreement between the Veterans' Board and the Treasury with regard to the use of surplus supplies for the equipment of the new hospitals. But allotments were finally made in May, 1922.

#### Supply and Demand.

It appears that the consultants were originally faced with an estimated need for 20,000 beds—4,000 for general medical and surgical cases, 8,000 for tuberculous cases, and 8,000 for neuro-psychiatric cases. It was found that no increased provision of beds was necessary in the general medical and surgical group, and that by October, 1922, the demand for beds for tuberculous cases would be satisfied. The only need remaining after that date was 1,800 new beds for neuro-psychiatric cases. The consultants call attention to the fact that a great deal of money was spent during the war for temporary hospitals which had to be abandoned. If the Government had had a Federal plan for its hospital work much that was wasted could have been preserved as permanent institutions to meet the present situation.

The consultants note the interesting fact that New York State and Pennsylvania, the two most populous districts in the country, were the most poorly equipped in Government facilities; but, as the wealthiest states in the Union, they had the best hospital facilities for their civil population. Therefore the provision of additional facilities in their case was left to the last. In connexion with Chelsea, N.Y., it is pointed out that, although sentiment for ex-service men ran high, when any suggestion was made for the erection of a hospital for the tuberculous, local sentiment was largely for any district other than that chosen by the investigators!

As each project was completed it was transferred to the United States Veterans' Bureau for occupancy by patients. An inspection by members of the Consultants' Board led to the conclusion that there is nothing better in the United States for the special care of disabled veterans suffering from tuberculosis and nervous and mental diseases than the institutions which have been provided under Public Act 381. The total expenses of the consultants, with their advisory committee and other experts, exclusive of clerical and office expenses, was 16,000 dollars for two years' work.

#### A Federal Hospital Programme.

The Report of the consultants is prefaced by a series of recommendations for a future programme of Federal hospitalization. It is advised that the subject should be one for continuous study in some Government office in which records should be kept of all hospitals throughout the States, and from which advice should be given with regard to the location, expansion, and equipment of hospitals. The standards for construction, equipment, and personnel should be changed from time to time as knowledge grows and conditions alter. The future economic use of the hospitals when they can no longer be utilized for the purpose for which they were built should be a matter of constant study.

The three purposes suggested by the consultants for hospitals when no longer needed for war veterans are: (a) transfer to the National Home for Disabled Volunteer Soldiers to be used for domiciliary care; (b) transfer to the United States Public Health Service for marine hospital bases; (c) the sale or transfer to the States in which they are located as part of their health and welfare equipment. It is advised, finally, that some plan of co-operation between the Federal Government and the States should be evolved so that the Federal authorities may guide and assist in making hospital practice uniform over the whole country.

THE French Association for the Study of Cancer will hold a congress at Strasbourg on July 23rd and 24th, when the following subjects will be discussed: (1) Experimental production of cancer, introduced by Drs. Bordet of Strasbourg, Fibiger of Copenhagen, Ichikawa of Sapporo (Japan), Pintimalli of Naples, and Murray (Director of the Imperial Cancer Research Fund, London). (2) Local and general reactions of the organism to cancer, introduced by Dr. Rubens-Duval of Paris and Woglom of the Crocker Institute of Cancer Research, New York. (3) Treatment by radium and x rays of epithelioma of the skin and buccal cavity, introduced by Dr. Bayet, Director of the Radium Institute at Brussels, and Dr. Regaud, Director of the Biological Laboratory of the Radium Institute of the University of Paris. The Congress will consist of (1) members (medical practitioners) who will pay a subscription of 60 francs, and (2) associates (medical students, and others interested in cancer, who will pay a subscription of 40 francs. Associates will be entitled to all the privileges of the Congress except the publication. The official languages will be French and English. The list of the papers intended to be read should be sent to the general secretary, Dr. G. Roussay, 21, Rue de l'Ecole de Médecine, Paris, before May 1st.

# British Medical Journal.

SATURDAY, APRIL 21st, 1923.

## MAN'S POSTURE: ITS EVOLUTION AND DISORDERS.

THE course of evolution has at times undergone, as the result of some apparently simple and trifling event, a change of the utmost importance and consequence—a change associated with the sudden opening up of new channels along which the current has flowed with almost torrential violence. Such a change ensued on the adoption of the erect posture, for is it not safe to say that everything which makes us what we are was only then made possible of acquirement?

Ever since the theory of evolution in its modern form was accepted, the adaptation of the human body to the erect posture has been a favourite study with anatomists, and a large number of interesting data, particularly in connexion with the bones, ligaments, and muscles of the body, have been recorded. Until recently, however, all attempts to explain them have been made in the main, if not entirely, on purely mechanical grounds. The discovery of hormones and the demonstration of their influence on growth has thrown a new light on the problem and has led to an extension of interest from the bones and ligaments to the viscera and the nervous system. A stage had been reached when it had become highly desirable that someone should collate the various contributions to scientific literature on the subject during the last century or so, and present the case in a clear, concise, and comprehensive form. Fortunately this has now been done, and by a man of science than whom none is more competent to deal with it. Sir Arthur Keith, whose course of lectures on the evolution of man's posture and the derangements with which it may be associated is concluded in our issue of this week, has not merely made a special study of the Primates, but has kept, as is his invariable custom, in close touch with the physiological and pathological aspects of the subject. No better instance of the happy conjunction of the man and the problem could well be imagined.

While he has treated the subject in a characteristically broad morphological manner, the morphology is deftly interwoven with practical suggestions of the greatest importance, so that it is in no sense academic or obtrusive but yet sufficiently in evidence to prove that it can provide the key to those problems of physiological anatomy on the correct solution of which the scientific practice of preventive and curative medicine alike depends. A knowledge, for example, of the evolution of the foot and of the perineal region can furnish the only safe lines along which to work in preventing or curing derangements of these parts.

It was inevitable that the change from the pronograde to the orthograde position should be associated with considerable disabilities, for the change affected practically every structure in the body to a greater or less degree, and it could scarcely be expected that all would be able to adapt themselves with complete efficiency to the new conditions. As a matter of fact, save in the abdominal region, Nature has been singularly successful in the compensatory measures she has adopted. Nothing, for instance, is more striking than the "simultaneous and harmonious adaptational" contrivances whereby equilibrium is secured or the respiratory act changed from a pronograde to an orthograde type. So delicate and so perfect is the adaptation that there will, we believe, be full agreement with Sir Arthur Keith when he says,

"we must postulate a much more elaborate mechanism controlling developmental processes than any we have knowledge of as yet." What the mechanism is we are left to conjecture, but that it exerts its effect largely through hormones is believed to be more than probable.

In the face of such success in other parts of the body it becomes interesting to inquire why there should be comparatively so signal a failure in the region of the abdomen. The failures here may be classified into those associated with weakness of the pelvic floor, and those connected with the various types of hernia and visceroptosis. As to the first it must be remarked that, whereas the floor is the highest part of the abdominal cavity in the standing pronograde animal, it is the lowest in the standing orthograde animal; in the former animals, again, the root of the tail is depressed and thus acts as a shutter supporting the perineum in any movement associated with an increase in the intra-abdominal pressure; in them, too, the vaginal orifice is a mere chink and is situated posteriorly where the support of the root of the tail is available. The comparative failure to provide an adequately strong pelvic floor in man would appear, therefore, to be due to the existence of several adverse influences. The liability to hernia in the region of the groin is no doubt in part due to defective parietal defences consequent on changes in the shape of the ilium and in the attachment of the oblique muscles of the abdominal wall, but there is probably another factor to be considered—namely, that of visceroptosis, a condition believed to be due to a disturbance of the reflex postural mechanism dependent on sensory fibres from the viscera and motor fibres to the parietal muscles. This mechanism may be in turn controlled by a hormone and be peculiarly susceptible to influences arising from errors of diet.

Perhaps the chief impression we receive from this valuable course of lectures is how very far growth is from being the simple process which it was aforotime thought to be. It is now seen that there is the closest and most intimate relation between the growth of adjacent structures. It appears, indeed, that, in certain parts of the body at any rate, growth affects collections of tissues rather than individual structures. Nor is the subject rendered more simple by the postulation of the influence of hormones, for these after all can only be imagined to act in the manner of a chemical stimulus. The source of the original impulse is still to seek, and must be found in the nervous system or inherent in the actual cells concerned. Although this must be the case the study of the action of hormones is of the greatest practical interest, for their experimental use in stimulating or holding in check the processes of growth is not beyond the range of possibility.

We commend these lectures to our readers with the greatest confidence as furnishing them with guiding principles and stimulating suggestions; the subject is peculiarly obscure, but obviously it has important practical bearings, not only for the surgeon but also for the medical profession at large, and to some extent also for the educationist. In congratulating Sir Arthur Keith on bringing to a satisfactory termination work on which he has been engaged during so many years we would take the opportunity of congratulating him no less heartily on his complete restoration to health.

## THE MEDICAL SERVICE OF KENYA COLONY.

THE health services in the various colonies and dependencies of the Crown, and more especially those in tropical areas, are obviously key services—that is to say, their maintenance upon an adequate basis is an essential condition of economic stability and development—and

any threat to their efficiency is matter for grave concern, not to the individual service or to the medical profession only, but to all who have the welfare of the colonies at heart. That the efficiency of the service depends ultimately upon the class of candidate attracted by the conditions offered is equally true. This is a sufficiently trite text, but unfortunately there are not lacking indications that the sermon is urgently needed. Of these indications the latest comes from Kenya Colony.

The essential facts of the case seem to be as follows. During the last two years the Colonial Government has been contending with conditions of the utmost difficulty and danger. On the one hand, post-war economic problems have been complicated by failure of the rains and consequent famine, and also by peculiar currency difficulties; on the other, development has been hampered by racial animosity and suspicion in the most acute form. Early last year the Colonial Office indicated that a reduction of 50 per cent. in the current estimates was essential to the stability of the colony, and the Bowring Committee of the Legislative Council was appointed to explore the possibilities in this direction. Its recommendations included the abolition of the local allowance to European Government servants, and a reduction in the estimates of the Medical Department of £50,000. The reduction of the local allowance was discussed in detail in a Current Note in the SUPPLEMENT to the BRITISH MEDICAL JOURNAL of June 24th, 1922, and is not for the moment in question, but it may be remarked in passing that the recommendation has not been accepted without modification, and an allowance of 15 per cent. in place of the original 50 per cent. has been conceded for the current year.

The proposals for retrenchment in the Medical Department comprise, according to a statement in the House of Commons by the Under Secretary of State for the Colonies, "the abolition of one post of senior medical officer, eight of medical officers, one of dental surgeon, and a number of other appointments." They "have been framed so as to affect as little as possible the principal centres of population, and they concern mainly the minor stations and those out-stations where other facilities exist or may be made available for medical attention. They have been closely examined by the late and the present Governor, and although the reductions have been effected with great reluctance, the Principal Medical Officer is satisfied that efficiency can be maintained." This statement is worth careful consideration. It discloses a position affecting the welfare of the colony, the interests of existing members of the medical service, and the general conditions of service in the Colonial Medical Services.

In the first place, then, we learn that the efficiency of the service is to be maintained, notwithstanding a reorganization involving not only the abolition of ten medical appointments (the Government dental surgeon is a fully qualified member of the medical staff), but a reduction of ten in the total personnel of the service. To maintain efficiency in face of a reduction of over 30 per cent. in a department not generally considered to be overstaffed would seem to be a surprising enough achievement. When it is further indicated that the localities concerned are the minor centres of population and out-stations, and that alternative facilities for medical attention may be available in these localities, we are even more mystified. Minor centres are not usually those where medical facilities abound. We fear that the explanation of the matter must be sought in a recent enactment (Ordinance 3 of 1922) empowering the Principal Medical Officer to license (for the purposes of private practice in the colony) assistant surgeons and hospital assistants who have completed their term of Government service. These persons, it must be

explained, are not fully qualified practitioners, although they have undergone a course of medical training and held subordinate positions in the service of the colony. The Dominions Committee of the British Medical Association warmly endorsed the protest entered at the time by the local Branches against this introduction of unqualified practice, regulated and licensed by a single Government officer, in place of the Medical Board charged with registration under the Medical Ordinances of 1910. If these are the "other facilities" referred to they can hardly be taken as the equivalent of the facilities withdrawn by abolishing a substantial proportion of the posts held by fully qualified medical practitioners.

Passing from the general aspect of the matter to its effect upon the medical service itself, we find the position equally unsatisfactory. Some at least of the officers affected are known to be men with a considerable period of service to their credit, but not yet entitled to retire on pension. Such medical officers had every reason to suppose that the service offered them security of tenure, and presumably entered into financial and other commitments accordingly. The Dominions Committee of the Association has been informed that they will receive a pension equivalent to that permissible in the event of retirement on medical certificate, and no other compensation. In view of the fact that the current Colonial List shows some twenty-three temporary medical officers in the several East African colonies, it is not, perhaps, too much to hope that the Secretary of State may find it possible to offer them alternative employment in lieu of such compulsory and inadequately compensated retirement. The prerogative of the Crown to determine the employment of a Government servant is of course beyond dispute, but it is not the least disquieting factor in the situation that the Colonial Office has sought to justify the present policy by the argument that the existence of this prerogative precludes the assumption that the appointments in question are permanent. Prospective candidates for the services will therefore be well advised to obtain an official interpretation of the statement in the current Colonial Office memorandum on colonial medical appointments to the effect that such appointments in the East African Colonies are, after a probationary period of two years, "made permanent" if service has been satisfactory. Security of tenure has in the past been reckoned not the least among the attractions of the colonial services, and its withdrawal must affect the quality of the candidates coming forward in the future. The precedent now established may prove detrimental to the Colonial Medical Services as a whole, and not merely to those in Kenya Colony.

The case of the dental surgeon may be mentioned as an illustration of the nature and probable effects of the present retrenchment. The post was created in 1913, and since 1915 dental service has been guaranteed to members of the East African Civil Service under the Code. In that year a Colonial Office subcommittee on dental facilities in tropical Africa recommended the confirmation of the appointment to the medical officer then holding it, and declared that only a very grave emergency could be held to justify taking the Government dental surgeon away from the work properly attached to the appointment and employing him on medical or other work not so attached. Such an emergency did, in fact, arise in the course of the war, and it was not till 1918 that this officer resumed dental work. In 1922, in spite of the prevailing financial stringency, the estimates provided for the extension of the work by the appointment of an assistant dental surgeon and two dental mechanics, but the Legislature refused to vote the money, and accordingly the dental surgeon

has in the interval dealt single-handed with a volume of work which would occupy the time of a staff of four.

It is to be feared—in fact experience dearly bought in similar circumstances elsewhere leaves no doubt—that an attempt to maintain the efficiency of the Kenya Medical Service under the conditions we have described must end in failure, with injurious results to the public health and economic development of the colony. It has been alleged on good authority that official neglect of the public health of the colony must tend to aggravate the political unrest at present existing, and the suggestion is not so far-fetched as at first sight it may seem. We have no detailed information as to the public health conditions in Kenya, but they are known to be primitive, as is inevitable in a new country with a new and changing population. Squalor and disease do not tend to produce a contented people, and a low standard of health saps enterprise. The relation between efficient public health administration and economic progress is direct, and is recognized by statesmen and legislators in this country. We can therefore well believe that the organization of a properly equipped and fully staffed Public Health Department in Kenya would go far towards solving the municipal tangle which persons well acquainted with the circumstances consider to be in part responsible for the racial question which is the cause of much embittered feeling not only in East Africa but in India.

### THE BUDGET.

MR. BALDWIN'S speech on Monday marks another milestone on the road from war finance back to the less disturbed and less sensational conditions usually associated with peace. That we have not yet reached that goal is sufficiently indicated by the inclusion in the estimated revenue for 1923-24 of £40,000,000 from miscellaneous special receipts, and £12,000,000 anticipated from the excess profits duty; the expenditure side of the statement shows an estimate of £73,655,000 for the Ministry of Pensions, a reduction of £16,336,000 on the corresponding estimate for 1922-23, but nevertheless a figure which shows very clearly how acutely Budgets for years to come will be affected by changes arising out of the war, even apart from payment of interest on the war debt.

The magnitude of the realized surplus for 1922-23 has been a surprise. Although Sir Robert Horne suspended the operation of the Sinking Fund in order to relieve the country by reducing taxation, yet, in fact, there was a realized surplus of £101,516,000, which, added to other sums included under the head of expenditure in the original estimate, has enabled the Treasury to issue out of revenue for repayment of debt the huge total of £126,227,000 in a single year. This result is to be attributed to several factors, but the outstanding features of the statement are, first, that income tax (including super tax) produced £50,000,000 more than had been anticipated, and thereby made good the balance of deficiency that would have been incurred on the other items of revenue; and secondly, that the expenditure was £91,404,000 less than the estimate. The existence of such wide variations is a matter for some regret, since the annual Budget debate is one of the few occasions on which Parliament, as a whole, takes an active part in government and exerts real influence not only on national policy but on its detailed development and administration. The departmental estimates form the foundation for the Government proposals and subsequently for the criticisms of the Opposition, and unless the margin of error in the estimates can be narrowed the most vital of all parliamentary proceedings must start from false premisses. Where, as in the

present instance, the actual result is more creditable to the taxpayer and more helpful to the future generation than that which had been anticipated, the pride of the occasion is apt to put a gloss over the danger inherent in unfulfilled expectations, and a word of warning is the more desirable.

Having made this point, however, we hasten to admit that last year was a peculiarly difficult one. The heavy arrears of income tax outstanding at its beginning were likely or unlikely to be received by the Exchequer according to the extent to which industry generally pursued an upward course or remained in the trough of the trade depression; and, in fact, the income tax surplus seems to have accrued largely owing to the slight but general improvement in industrial conditions, which led to the clearing off of outstanding claims to a greater extent than the Treasury felt able to anticipate. On the expenditure side a factor of the utmost importance is the continuance of a high general price level. Departmental estimates for any particular year have to be prepared, discussed, and revised before the close of the previous year, and it is obvious that some price level has to be assumed for the purpose. If the following twelve months witness a general fall, it is clear that an automatic saving on the estimate should result. For this reason it is essential that constant care and supervision should be exercised, and unremitting pressure brought to bear on the departments to ensure that these savings should not be dissipated in performing the duty provided for in a manner different from, even if more effective than, that contemplated in the original estimate. In other words, if the work was expected to cost £1,000 and it is found that it can be done in the way desired for £850, then only that sum should be spent on it. Mr. Baldwin seems to be fully alive to this aspect of the question, and his omission to provide any special margin for Supplementary Estimates was avowedly intended to bring pressure on departments finding it necessary to put them forward to provide for them out of savings elsewhere.

The outstanding feature of the estimated expenditure for 1923-24 is the inclusion of £40,000,000 Sinking Fund for repayment of debt, coupled with an undertaking to increase that provision for the two following years. The wisdom of this step is contested in some quarters, but where the natural bias of mankind is in favour of postponement in such a case as this, the contention that we may reasonably leave the immediate future to take care of itself needs to be buttressed by stronger arguments than we have yet seen. It is impossible to dogmatize on the point, so many tendencies and probabilities enter into the problem, but Mr. Baldwin's action has the merit of courage and deserves to find its justification in success. The measure of the courage required can be found in the fact that the £40,000,000 allocated to Sinking Fund—as against nothing last year—is a greater sum than the surplus of £36,000,000 left, on the basis of present taxation, to be distributed in reduction of the taxpayers' burden. The details of this reduction are set out in our Parliamentary Notes. The sixpenny reduction in the standard rate of income tax is undoubtedly sound, and though there may be some legitimate disappointment in the continuance of the existing sugar duty and also as to the proportions in which the fall in the retail price of beer is to be divided between the brewer and the Exchequer, the relief to the "indirect" taxpayer seems to have been reasonably apportioned. The minor alterations in the postal and telephone rates are welcome, not only in themselves, but as tending to remove a cause of irritation. It is noteworthy that the long-continued protests against the Corporations Profits Tax—a fairly new but by now almost friendless impost—proved successful to the extent

of having obtained a reduction in the future, though the yield for 1923-24 is not expected to be affected thereby.

There remains the question of a tax on betting, which is to be the subject of inquiry by a Select Committee. Judgement must be suspended for the present, until some solution of the problem of administering such a tax is put forward. On theoretical grounds it would certainly seem that a man making a bet can afford to pay a tax as well as another who may prefer to take his pleasure or excitement in attending a taxed entertainment.

Mr. Baldwin's first Budget appears to be sound and reasonable; it strikes us as typically British in its mixture of shrewdness, foresight, and determination, and as one with which its author may be well content.

#### OCTOCENTENARY OF ST. BARTHOLOMEW'S HOSPITAL.

THE celebration of the eight hundredth anniversary of the foundation of St. Bartholomew's Hospital will be held on Tuesday, June 5th, and will be continued on the following days. It will begin, as is fitting, with a service in the Priory Church of St. Bartholomew the Great at 10.30 in the morning. An hour later a pageant will be held within the gates of the hospital. The pageant will consist of five processions—the first one formed by Augustinian canons chanting the ancient hymn used at the foundation of an Augustinian Priory, for it must be remembered that the hospital was under the rule of this religious order for the first four hundred years of its existence. The second procession will illustrate the return of Rahere—the founder of the hospital—from his pilgrimage to Rome. The third procession will show King Henry VIII giving the charter for the refounding of the hospital to the Lord Mayor and citizens of London, and Mr. Arthur Bouchier has promised to enact the part of the King. The fourth procession will show a detachment of the R.A.M.C. with an ambulance such as was used in the great war. The final procession will be formed by H.R.H. the Prince of Wales, accompanied by the treasurer, the chief officers, the medical, surgical, and nursing staffs of the hospital. The processions being ended there will be a luncheon for the delegates and others at the invitation of the Lord Mayor. In the afternoon the Prince of Wales, as president of the hospital, will receive congratulatory addresses in the Guildhall, the addresses being presented by the delegates nominated by the English-speaking universities and colleges. Later in the afternoon a series of tableaux will be shown in the Great Hall of the hospital. The tableaux, illustrating various picturesque events in the long history of the hospital, will be produced by a committee of Royal Academicians under the presidency of Sir Aston Webb, and Sir Alexander Mackenzie, Mus.Doc., will provide appropriate music. There will be a conversation in the evening, when the hospital square will be illuminated. A memorial volume containing a short but well illustrated account of the hospital, past, present, and future, has been prepared. A medal has also been struck from the design made by Mr. Charles L. Hartwell, A.R.A., and it is intended that each delegate shall receive a copy of the book and a medal. The Students' Union of the hospital will reproduce Bartholomew Fair as it was in the time of King Henry VIII. Booths will be erected at which various goods will be on sale, and there will be a charge for admission. The old English sports of quarter-staff, wrestling, tumbling, and acrobatic performances will be shown. A souvenir programme will be sold at the fair. It is illustrated and will contain a short history of the hospital. It is hoped that it may contain contributions from the pen of the Poet Laureate—a former member of the staff of the hospital—and from that of Mr. Rudyard Kipling. There will also be exhibitions of the charters, portraits, prints, books, and surgical instruments which are more especially connected with the history of the hospital. The celebration will continue over the next two or three days of the week, and will be brought to a conclusion by an especial meeting of the Rahere Lodge of Freemasons to

be held in Freemasons' Hall on Friday, June 8th. It is a remarkable testimony to the liberality of the citizens of London and of the Governors that no part of the expense of the celebrations will fall upon the hospital, for the whole cost has been guaranteed.

#### PROPOSED INTERNATIONAL ASSOCIATION OF BRAIN WORKERS.

SOME three years ago M. Henri de Jouvenel, one of the French Delegates to the League of Nations, succeeded in establishing in France a *Confédération des travailleurs intellectuels*. This was the first national association of brain workers and now has 150,000 members; similar associations have been formed in eight other countries. A meeting of representatives of these associations was held recently at the Sorbonne, the headquarters of the University of Paris, with the countenance of the French Government and under the honorary presidency of M. Léon Bourgeois, one of the most universally respected of French statesmen. It was attended also by "observers" from nine other countries. Among the "observers" present were persons nominated by the several British societies, among others the British Medical Association, which was represented by Dr. Gustave Monod. The meeting first of all received communications with regard to the position in the various countries, and after a brief discussion it was decided to found a *Confédération internationale des travailleurs intellectuels*—that is to say, an international association of brain workers. A committee was appointed, consisting of two delegates from each of the eight countries having an organized confederation, and an "observer" from each of the other countries represented; the latter having only consultative privileges. This committee was instructed to take steps to invite those countries which had not already done so to establish associations of brain workers and to draw up a constitution for the international association; the draft is to be submitted to the national organizations and afterwards considered at a meeting to be held in Paris before the end of this year. Dr. Monod informs us that medical societies in France are beginning to join the French confederation. The Association Générale des Médecins de France joined a short time ago, and on April 11th the members of the Therapeutic Society of Paris, a purely scientific body, unanimously resolved to join also. Among the objects the organization has in view is the prolongation to eighty years of the period during which the author has a property in artistic and literary creations, and to extend this principle to scientific workers. With this object it will seek to bring into existence an international code governing the right in intellectual property.

#### INSULIN FOR SALE.

THE announcement made by the Medical Research Council in the memorandum published this week (p. 695), that the quantity of insulin now being made in this country is sufficient to warrant its sale to medical men and hospitals, will be received with interest by the profession, which has been anxious to try the new remedy, and with high hopes by sufferers from diabetes mellitus who have read of the remarkable effects it can produce. The sale is not to be entirely unrestricted, but the conditions proposed by the Ministry of Health are not unreasonable, and are probably necessary at the present stage. The supply of insulin is still limited; moreover, it is a potent agent, and the risks that may attend its administration must be borne in mind. Given to suitable cases of diabetes mellitus and in appropriate doses, its effects upon the sugar in the blood and its excretion in the urine are remarkable, and when given in diabetic coma, at any rate at its onset, highly dramatic. But if imprudently used in diabetes or given to inappropriate patients dangerous symptoms may rapidly be induced. The note prepared under the direction of the Medical Research Council and issued with the remedy by both of the manufacturers and firms which are at present able to supply it states that "while the use of insulin is unnecessary, and therefore not desirable, in the milder cases of true diabetes mellitus, it is

definitely dangerous in cases of the so-called renal glycosuria or diabetes innocens, in which the condition is not due to defective use of carbohydrate, but to failure of the kidney to hold back the normal proportion of glucose in the blood, so that the patient is already in a condition of persistent hypoglycaemia. By still further reducing the blood sugar, insulin will aggravate this condition, and the patient will be abnormally liable to the unpleasant and alarming symptoms ordinarily associated with excessive dosage of insulin," as described in detail in our columns on January 6th (p. 11). The danger of giving too large a dose or administering it not in due relation to the diet is also pointed out in the note, which should be studied along with the papers by Macleod, Banting, and his colleagues, published recently in the *JOURNAL*. Great credit is due to the British firms for the enterprise and skill which have enabled them to produce insulin on a commercial scale within a space of time which, considering the difficulties that had to be overcome, is remarkably short—some three or four months. Not only have they accomplished this, but, acting on the results obtained at the National Research Institute under the direction of Dr. H. H. Dale, they have succeeded in preparing a concentrated solution so that the dose is small—much smaller than at first seemed possible. The excellence of the result, and the rapidity with which it has been attained, afford a good example of what can be achieved by the skilled workers in a commercial laboratory who are inspired and directed by research of the highest and most accomplished order.

#### THE ROCKEFELLER BUILDINGS AT UNIVERSITY COLLEGE, LONDON.

THE visit of the King and Queen to University College and its Medical School to lay the foundation stones of the new obstetrical hospital and the new nurses' home will be paid on Thursday, May 31st, at 3.15 p.m. These two buildings are in Huntley Street, whose northern end is already occupied by one side of the medical school buildings which front the side of the hospital in University Street. Their Majesties will also formally open the new Anatomy Institute of University College, recently erected in Gower Street immediately south of the College quadrangle and west of the Physiological Institute, which also has been enlarged. It was announced nearly two years ago that the Rockefeller Foundation had arranged to give sums amounting together to £1,205,000 to University College and University College Medical School with the aim of forming in London an ideal medical school equipped in all departments on the most modern lines. Of the total amount given to the College the sum of £370,000 was for an Institute of Anatomy and for additions to the staff of that department and certain others. The cost of the site, building, equipment, and library of the Institute of Anatomy was estimated to be £190,000, leaving a capital sum for maintenance of £180,000, calculated to provide £5,000 a year for additional staff in the Anatomy department, £2,500 in the Physiology department, and £1,500 in other departments. University College Hospital fills an island site, so that it is not susceptible of enlargement. The number of beds at the disposal of the Directors of the Clinical Units recently established was considered to be too small and it was not found possible to make proper provision for obstetrics. It was decided, therefore, to take over the space in the nurses' wing and to build a new nurses' home and a new obstetrical hospital. The Rockefeller Foundation arranged to give £400,000 to University College Hospital and Medical School for building and reconstruction and £435,000 for maintenance. The income of this endowment fund is to be used for the furtherance of medical education and research in the Medical School, but a sum not exceeding £16,000 a year is to be applied to the upkeep of the 120 beds allocated to the purposes of the Medical and Surgical Units until such time as money can be otherwise raised, when the income of the endowment will be restored to its original purpose of helping medical education and research. The new buildings for the Obstetrical department it is estimated will cost £110,000, and will provide sixty beds; the

responsibility for their maintenance will fall on the corporation of the hospital, which will have to increase its present income by some £15,000 to £20,000 a year.

#### THE LEGAL PERIOD OF GESTATION.

At a meeting of the Medico-Legal Society on April 17th Dr. T. W. Eden spoke on the medico-legal aspects of the duration of pregnancy. The old obstetricians, he said, had very definite opinions as to the normal length of pregnancy, and paid small regard to the difficulties of the subject; in the Gardner peerage case in 1816 one of the medical witnesses laid it down that forty weeks from conception was the extreme period to which pregnancy could be prolonged. It was English law at present that points of physical resemblance did not constitute evidence which could be received in court. Possibly at some future time reliance might be placed on evidence as to certain reactions of the blood, based on the fact that the characteristics of blood-grouping were transmitted on Mendelian principles. Meanwhile, in legitimacy cases it was necessary to fall back on calculations as to the period of pregnancy. To determine the normal duration of pregnancy was a complex problem, and did not admit of an exact solution. Pregnancy commenced in profound obscurity, and its termination with the birth of the child was frequently not at the end of the normal period, whatever that might be. The difficulty of arriving at the date of fertilization was that, although there might be reasonable certainty that the spermatozoa were in the genital tract, there were no means of ascertaining at what time the egg cell was there to meet them. In cows and mares the variation in either direction from the mean of a number of carefully observed gestations was, in both species, 12.5 per cent. The normal duration of human pregnancy, although variable, was not variable to the same extent as in animals. There were two starting-points for the calculation of pregnancy—namely, the date of intercourse, and the date of the last menstruation. Fertilization was most likely to occur during the week following the menstrual period, but there were opportunities for fertilization at any point in the menstrual cycle, which made this method of calculation very difficult. Some women, moreover, continued to menstruate for two or three months after conception, though many of the instances in which this was alleged to have occurred were not really cases of menstruation at all, but of bleeding from some pathological cause. A number of estimations based on the last menstrual period showed that 15 per cent. of the pregnancies went on to the 39th week, 24 per cent. to the 40th week, and 22 per cent. to the 41st week. Similar calculations from the date of coitus showed that 45 per cent. went on to the 40th week, and if the three weeks were taken (the 39th to the 41st week inclusive) the proportion of pregnancies which terminated within this period was 77 per cent. In common practice 280 days was reckoned from the cessation of the last period, or 274 from the date of the last coitus, but variations up to three weeks might be accounted for by the uncertain incidence of ovulation. Much wider variations were sometimes recorded, even in successive pregnancies in the same woman. One instance was given by Taussig, in which the same woman had pregnancies of 277, 325, and 285 days. Cases in which pregnancy exceeded 300 days from the last menstruation were rare; in Germany it was stated that 6 per cent. of the pregnancies exceeded that period, but in this country the proportion was certainly less, and it was quite possible that racial characteristics were influenced by variations in the period of gestation. The longest pregnancy (331 days), based on calculation from the last coitus, was that which formed the subject of the Gaskill case,<sup>1</sup> and a period of 336 days was recorded in another case in which the reckoning was from the commencement of the last menstruation. On the question how far the length of the gestation process might be judged from the characters of the child when born, Dr. Eden said

<sup>1</sup> For Lord Chancellor Birkenhead's judgement in this case see *BRITISH MEDICAL JOURNAL*, August 6th, 1921, p. 222.

that one medical work quoted Shakespeare as the authority for the statement that a child might be born "full fourteen weeks before the course of time" and reach a lusty maturity, but if the passage (*King John*, Act I) were referred to it would be found that Shakespeare made no such claim, for there was confessed illegitimacy. To the question of Philip Faulconbridge, the bastard—

Therefore, good mother;  
To whom am I beholden for these limbs?  
Sir Robert never help to make this leg—

Lady Faulconbridge replied:

King Richard Coeur-de-Lion was thy father;  
By long and vehement suit I was seduced  
To make room for him in my husband's bed.

The conditions which governed the weight and development of the child were largely unknown, and the same was true of the length, though this was a rather more constant factor. In protracted gestation the weight of the child should be much above the average. In cases in his own private practice in which gestation had been prolonged to from 290 to 300 days the weight varied from 8½ lb. to 12 lb., the average being 9½ lb. Cases which went beyond 320 days were extremely rare, and the facts with regard to them should be closely scrutinized; if the circumstances lent themselves to misrepresentation confirmatory evidence should be sought, and in particular it should be noted whether the weight and dimensions of the child were much above the average. In the course of a brief discussion Sir Bernard Spilsbury said that on examining stillborn children he had found that some of the signs by which maturity was commonly judged were absolutely valueless, and that the weight varied extraordinarily in the full-term child, though length was a rather more constant factor. It had been suggested by some observers that the ossification of the sternum had diagnostic significance, but his *post-mortem* examinations did not support this view. The ossification of long bones, however, especially the lower end of the femur and the upper end of the tibia, was more reliable. Lastly, Dr. Eden suggested that in the living child radiographs of the ossification of the long bones might prove useful in a disputed case.

#### THE TEACHING OF OBSTETRICS AND GYNAECOLOGY.

THE Ministry of Health has issued a report on the arrangements for teaching obstetrics and gynaecology in the medical schools of Great Britain. It has been prepared by Dr. Janet M. Campbell, senior medical officer for maternity and child welfare in the Ministry of Health, as a part of the inquiry she is conducting into the causes and prevention of maternity mortality. A brief introduction, in which the history of the subject is sketched, is followed by a long series of detailed notes on the existing arrangements at a number of medical schools. This, which occupies about half of the bulk of the report, is followed by some general observations, and these again by a discussion on some particular matters, such as ante-natal or pre-maternity clinics, midwifery districts and lying-in hospitals, puerperal infection, ophthalmia neonatorum, and infant welfare. In the observations on the teaching of midwifery the report fairly represents present opinion upon the subject, which has undergone considerable modification within the last twenty years. The recommendations follow pretty closely the decisions reached by the General Medical Council, and include the suggestions that a sufficient number of maternity beds should be provided to enable all students to obtain suitable in-patient practice; and that the department of obstetrics and gynaecology should be a single whole, and not divided—an experiment in this direction made in Edinburgh was abandoned at the first opportunity. It will be remembered that a Memorandum on Medical Education in England, by Sir George Newman, was issued in 1918. We understand that another memorandum by him, dealing with recent advances, is in the press. When it is published we shall have an opportunity of reviewing the whole situation and of recurring to this subject of the teaching of obstetrics and gynaecology.

#### HOSPITAL CONTROL IN THE UNITED STATES.

Two years ago, under circumstances stated in the article published this week (p. 685), the United States Treasury appointed a medical committee to advise on problems connected with the care of soldiers, sailors, merchant seamen, and other persons employed by the Government who had been disabled through service in the war, and especially with cases of tuberculosis and of nervous and mental disease. The report of the committee goes a great deal beyond its reference, and the "consultants on hospitalization," as the committee was called, have based upon the data they accumulated certain "recommendations for future Federal hospitalization" which seem to suggest something very like a State organization of the civil hospital system. The consultants advise that the hospital problem of the United States ought to be the subject of continuous study in an office of the Federal Government, which should keep records showing the situation, size, character, and use of all State, municipal, and civil hospitals. It should also advise on suitable sites for new hospitals, expansion of existing hospitals, standard plans for building, equipment, and personnel, and costs of construction and maintenance. The standards for construction, equipment, and personnel would be changed from time to time as knowledge grows and conditions alter. The office would be guided in the advice it gave by movements of population, functions of government, the future use to which buildings can be put, by transport, medical, and nursing facilities, and by the Federal relation and assistance to State, municipal, and civil health functions; the aim would be to afford uniform care to the citizens of the United States, free from the influence of individual or local interest. The number of hospitals constructed by the United States Government for disabled soldiers and sailors being greater than can be utilized for the purpose, the consultants recommend three methods of future disposal: (a) transfer to the National Home for Disabled Volunteer Soldiers—presumably institutions similar to our Chelsea Hospital—for domiciliary care; (b) transfer to the United States Public Health Service for marine hospital bases especially in the great shipping centres; (c) sale or transfer to the States in which they are located as part of their health and welfare equipment. The evolution of a plan of co-operation between the Federal Government and the various States would, in the opinion of the consultants, lead eventually to guidance and assistance by the Federal authorities in making hospital practice uniform over the whole country. Such is the very large scheme the consultants have tacked on to their recommendations for the care of 20,000 war veterans. They recognize that the intervention of the central authorities in hospital questions, even if limited at the outset to advice, will in the long run tend to uniformity and to the adoption of standardization in construction, equipment, and personnel. We must confess that the views are somewhat depressing, hospitals at the end of the report are somewhat depressing, and in appearance resemble plans for barracks or factories. To economize time in erecting for the disabled hospitals of which there was urgent need, it is probable that standardization was useful, but for less urgent civil needs competition between localities in hospital construction in a Government office healthy. Again, is centralization in a Government office desirable? It is true that there is much debate at present in this country about the overlapping of hospital provision, but it may be asked whether, if such overlapping exists, it will be remedied more effectually through supervision by a Government department or by promoting gradually the voluntary co-operation of institutions. The American consultants recognized the existence of a difficulty in the relation between the Federal Government and the States of the Union. In this country the problem of the relation between county and borough councils and the Ministry of Health is to some extent similar. It is worth inquiry whether under a scheme of State supervision of hospitals in this country some of the minor problems faced by the American consultants would not arise. They considered that a number of psycho-neurotic and neurasthenic type were being wrongly retained in hospital

for treatment. Would it be better in this country that a Government department should inquire into such matters or that the medical staff should be left to discover the best method of treatment by their own observations and by communications published by other observers? It seems not impossible to imagine some such assumption of authority in matters of treatment by a Government department entrusted with hospital supervision; just as in the case of the psycho-neurotics, the consultants advised a "uniform policy of treatment under central control." Again, the influx observed in America of men under State provision into hospital during a period of great depression in trade is suggestive. Even more interesting is the statement of the consultants that in general the civil institutions were much more economical in their administration than the Government institutions. If the Federal Government in the United States of America is on the eve of a great experiment in "hospitalization," it will be interesting to watch the results.

#### FELLOWSHIP OF MEDICINE.

At a meeting of the Fellowship of Medicine held on April 13th at the Royal Society of Medicine a scheme, brought forward by the non-undergraduate hospitals in London, was considered, and it was decided to accept this scheme and take immediate steps to put it into operation. The scheme is devised to meet the needs of two distinct classes of post-graduate students—namely, those requiring short general refresher courses and those requiring advanced courses in the special departments of medicine and surgery. It is proposed to arrange the short refresher courses on the group system, centred in a general non-undergraduate hospital affiliated with certain special hospitals in its neighbourhood, each group making itself responsible for three or four such courses during the year. It is hoped that four, or perhaps five, of these groups will be founded in London. The programme will open with a course at the Prince of Wales's General Hospital, Tottenham, assisted by the special hospitals belonging to the North-Eastern group, from June 11th to 23rd. Further details regarding this course and others to follow throughout the year will be announced. For graduates requiring more advanced instruction it is proposed that each of the special hospitals should undertake two or three courses during the year, and in these it is hoped that specialists from the undergraduate hospitals will be willing to come to the special hospitals on the invitation of the staff and assist in lectures and demonstrations.

#### THE OPHTHALMOLOGICAL SOCIETY'S CONGRESS.

The detailed programme has now been issued for the annual congress of the Ophthalmological Society of the United Kingdom, which will be held at the house of the Royal Society of Medicine, 1, Wimpole Street, W., from Thursday, April 26th, to Saturday, April 28th, inclusive. The President, Dr. A. Maitland Ramsay, will give his opening address at 10 a.m. on April 26th. This is to be followed by papers, by Mr. Treacher Collins and Sir William Lister, on angioid streaks in the fundus oculi; the technique of cataract extraction will be considered by Mr. Affleck Greaves, Mr. Foster Moore, Mr. D. V. Giri, and Mr. Charles Killick. At 2 p.m. a discussion on disorders of the blood and their ophthalmological manifestations will be opened by Sir Humphry Rolleston, Sir Frederick Andrewes, and Dr. W. C. Souter; Dr. A. J. Ballantyne will follow with a paper on retinal vascular disease, and fundus lesions in diseases of the blood. At 5 o'clock the Bowman lecture, on ocular aspects of pituitary body disorders, will be given by Professor George E. de Schweinitz, President of the American Medical Association. The congress dinner will be held that evening at the Langham Hotel. The principal business on the morning of April 27th will be a discussion on the diagnostic significance of proptosis, to be opened by Mr. Wilfred Trotter, Mr. H. Fisher, and Dr. Angus MacGillivray. In the afternoon a clinical meeting has been arranged at the London Hospital; cases and specimens

will be shown and the hospital will be open for inspection. The evening session will be devoted to demonstrations of cases and apparatus and the reading of miscellaneous papers. On the morning of April 28th, after a brief business meeting at 9.30, further papers will be communicated.

#### SIR WILLIAM DALBY MEMORIAL PRIZE.

LADY DALBY has recently handed to the Royal Society of Medicine the sum of £500 to be invested for the purpose of providing a perpetual memorial of her husband, the late Sir William Dalby, who was a well known otologist in London. The trust deed provides that the interest on the capital sum is to be accumulated for five years, when the product, less expenses, is to be awarded as a prize to the person who, during the previous five years, has produced the best original work done or published for the advancement of otology. The prize will be awarded by the Council of the Royal Society of Medicine upon the recommendation of the President and Vice-Presidents of the Section of Otology. The Society has one other similar fund, founded in memory of Dr. R. T. Nichols; under it the proceeds of a sum of £2,200 is awarded in recognition of the most valuable contribution to the prevention of puerperal septicæmia. It has also a Gibson Scholarship to assist medical women in research work. The Society not long ago received a bequest of £500 for an annual Lloyd Roberts lecture. It values very highly certain bequests and gifts it has received for its building and library. Thus its largest lecture room, the Robert Barnes Hall, was founded with a sum of £4,000 to commemorate Dr. Robert Barnes, a famous obstetrician in his day; and the Marcus Beck Laboratory, founded in memory of that beloved surgical teacher; it has also the Marshall Hall Room, by which the library facilities are improved, the Chalmers room, in which the library of the late Dr. A. J. Chalmers is housed, and a library room inscribed to Sir William Allchin. It has also two committee rooms, one to the memory of Henry Louis Florence, and the other to Joseph Toynbee; and finally the Frederick J. Gant bequest of £500 for the purchase of books to enlarge the Gant Library. The charters and by-laws provide that even in the event of the present building being destroyed or given up the name commemorated shall be preserved in any new building by the appropriation to it of a similar room.

#### THE OPHTHALMIC HOSPITAL AT JERUSALEM.

THE thirty-first report for the year 1922 of the committee of management of the Ophthalmic Hospital maintained at Jerusalem by the Order of St. John of Jerusalem shows how much good can be effected by methodical work, even in a country so backward as Palestine, which teems with eye diseases. It is a matter for satisfaction that there should be an up-to-date hospital in its capital for the treatment of these conditions. During the past year a new out-patient department room, which was badly needed, has been built. The Patriarch of Jerusalem has presented a site, and plans for an annex to the hospital to be erected on it are being prepared; at present, however, the cost of building prevents any active work in this direction being undertaken. The report of the warden (the senior British member of the staff) is largely statistical; the number of new cases seen was 12,651, and the total consultations numbered 57,848; the number of in-patients admitted was 1,268, and 2,859 operations were performed. Of new patients more than half were Moslems, a quarter were Christians, 1,393 were Jews, and 8 were of other religions. Of the new cases 1,174 were blind in one eye and 460 were blind in both. It is interesting to note the rapid increase in the number of spectacles ordered for patients; in 1919 spectacles were prescribed in 269 cases in 1920 in 475 cases, in 1921 in 760 cases, and last year in 1,148 cases; ophthalmic surgeons will appreciate the amount of work these figures indicate. Trachoma, of course, forms the chief bulk of the out-patient work, and acute conjunctivitis is

an easy second. Palestine suffers as heavily almost as Egypt from trachoma, and in some districts 97 per cent. of the inhabitants are infected by it; in school children the returns show an average of 74 per cent. for the country as a whole. The hospital is still below pre-war standard; in particular the bedsteads should be replaced by proper English hospital bedsteads; those in use are mostly of the army folding pattern, and all of them saw hard service in the war. An illustration appended to the report shows the hospital and the new out-patient building.

#### BRITISH OTO-LARYNGOLOGISTS IN SWEDEN AND HOLLAND.

THE Section of Oto-Laryngology of the Swedish Society of Physicians has invited a certain number of representatives in this country to deliver in Stockholm lectures on subjects with which their work has been identified. To suit their convenience the meeting in Stockholm has been arranged for Whitsuntide. Mr. Arthur Cheate (London) will lecture on the etiology and prevention of chronic middle ear suppuration, Sir StClair Thomson (London) on cancer of the larynx, Dr. Logan Turner (Edinburgh) on the occurrence of metastatic tumours in the larynx, with the description of a case, and Dr. Brown Kelly (Glasgow) on the significance of certain pharyngeal signs and symptoms. On their way to Sweden, the lecturers have been invited to join in the summer meeting of the Dutch Oto-Laryngological Society at The Hague on May 12th and 13th.

### Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

#### The Budget Statement.

MR. BALDWIN presented his Budget on April 16th in a speech which occupied only an hour and a half and was businesslike and straightforward. He showed that the financial year just closed had steadily got better as it advanced. Home and foreign trade had improved, unemployment, though still grievous, had decreased, and Government securities had appreciated. A good sign was that Post Office Savings Bank deposits, which had fallen in the first three months of last year, had enlarged by more than a million and a quarter sterling in the three months of this year.

The surplus of 101½ million from a total revenue of £914,012,000 was obtained not by excess of revenue over estimate, but by the prompt application of drastic economy. The revenue gave 3½ million more than was anticipated—a fact due mainly to a surplus on death duties of nearly 9 million and on income tax and super-tax of over 50 million, which counterbalanced the failure of revenue under some other headings to come up to expectations. What made the income tax collections especially remarkable was that a huge sum of arrears (over £100,000,000 of income tax and super-tax) had been largely gathered in, and the current collection maintained. The surplus of 101½ million on the balance sheet had already according to law been appropriated to meet maturing liabilities. In regard to savings, the Chancellor mentioned as chief items 27 million on the fighting services, 55½ million on civil votes, and 6 million on the provision made for supplementary estimates.

The dead weight debt on March 31st, 1922, was £7,676,000,000. The corresponding figure at the end of this year was £7,773,000,000, but the increase was only in face value due to the conversion of various war bonds and to the inclusion of arrears of interest due to the United States in the capital of debt. Thus corrected the figures would show an effective reduction of 149 million face value. Moreover, the taxpayer would have saved by the conversion of bond debt £750,000 a year interest and 4½ million in premiums payable on bonds as they matured.

Mr. Baldwin said that in two years there had been a drop of 247 million on the ordinary estimates and of 82 million in special expenditure. He did not intend to provide any special margin for supplementary estimates, but to revert to the pre-war practice of providing for them out of savings elsewhere without upsetting the general total. Last year debt redemption was nominally suspended; Sir Robert Horne reckoned that he might have to borrow in order to maintain the fund which was earmarked for that purpose as regards various war bonds, but this was not necessary. Mr. Baldwin said that he proposed to include in the Finance Bill a clause to give altogether a sinking fund of 40 million this year, increasing it to 45 next and to 50 afterwards—a sum approximating to the yields of the death duties. This would also provide for the sinking fund for the American debt; the policy was essential for sound finance. Unless proper

steps were taken to deal with the National Debt, in time it might be found an intolerable burden. Incidentally, he alluded to the large savings being effected and (as he hoped) to be effected by the conversion of stock to a lower rate of interest. He calculated that, as compared with actual receipts last year, Customs and Excise would give about 6½ million less, motor vehicle duties £929,000 more, estate duties 2½ million less, income tax nearly 35 million less, super-tax over 6 million less, excess profits duty nearly 10 million more, partly on account of arrears, and corporation profits tax a million more. He looked for an increase of a third of a million in the postal service, a fall of a quarter of a million on the telegraph service, and an advance of nearly 1½ million on the telephone service. Reckoning in other figures, he budgeted for a diminished revenue of £61,362,000 as compared with what was obtained last year, and for a total revenue of £852,650,000. With an estimated expenditure of £816,616,000, he was left with a surplus of about £36,000,000.

Before stating his proposals for dealing with this balance Mr. Baldwin announced intended legislation to apply some of the recommendations of the Royal Commissioners of Income Tax to meet evasion. He had selected for the present several of the more important. He should ask that the existing three years of time limit for making the income tax and assessments and surcharges should be extended to six, and that there should be a similar extension for the recovery of statutory penalties, with an increase in the amount of some of the smaller penalties. He should propose a corresponding increase to six years for claim for repayment where no specific time limit was prescribed. He would propose also to rectify the machinery for collecting income tax from certain pensioners and servants of the Crown employed abroad, but chargeable here from time to time when on leave. It was his duty to remember that next year revenue for several reasons might not be so good and to contemplate suggestions for new taxation. In that connexion he would ask the House to appoint a Select Committee to consider taxation on betting.

The first reductions announced by Mr. Baldwin were in postal charges. The rate of foreign letters would be reduced to 2½d. for the first ounce, plus 1½d. as at present for each succeeding ounce, and the rate for imperial letters above the first ounce would be lowered from 1½d. to 1d. an ounce. The inland printed paper rate would in future be 3d. for every two ounces. On the telephone side a reduction would be made of 10s. in the annual rental of ordinary telephone installations, and there would be reductions in the annual charge for extension instruments; the free radius outside the London area would be extended from one mile to one and a half miles from the subscribers' exchange. The fee for local messages from local call offices would be reduced from 3d. to 2d., and there would be minor reductions on short-distance trunk calls. Mr. Baldwin regretted that he could not see his way to reduce the sugar duty. The price was rising in the world market on account of an expected shortage in supplies, and his view was that in these circumstances a reduction in duty, which would lead to an increased demand, would not, at any rate after a short time, benefit the consumer, but would go to the seller. He had therefore turned his attention to commodities mainly produced in this country. He proposed to reduce the beer duty, making a reduction which would allow of the price being lowered by 1d. a pint all round. The duty was assessed on the standard barrel, which meant it varied in accordance with the gravity or strength of the beer. If the duty on the standard barrel were reduced by an amount which represented 1d. a pint on the average, it would mean more than 1d. on strong beer and much less on light. To meet these conditions he thought the best course would be to keep the present duty of 100s. per standard barrel and effect the reduction by giving a rebate on each bulk barrel of beer whatever its strength. He did not intend that the full cost should fall on the Exchequer. He was satisfied that the brewers could afford 4s. out of the 24s. involved. The only qualification to change would be that the full rebate could not be allowed for beers of very low gravity. Table water duty, now levied at 4d. a gallon on sweetened table waters, would be reduced to 2d. a gallon, and the duty of 4d. a gallon on cider would be abolished.

Finally, Mr. Baldwin stated that he had resolved to reduce the income tax by 6d. He believed that the relief in taxation would thus be spread over the widest possible area and a stimulus to trade afforded. The reduction would cost 26 million in a full year. This year reduction, taking effect as from April 6th, would cost 19 million. He recognized, moreover, that the corporation profits tax was not a good tax, and he proposed to reduce the rate from 1s. to 6d. He summed up by saying that all these reductions would cost together £34,150,000 in the current year, and next year about £47,250,000. The final balance sheet for 1923-24 would thus be:

Revenue	...	...	...	£818,500,000
Expenditure	...	...	...	816,616,000
Leaving a nominal margin of	...	...	...	£1,884,000

#### The Payment of Insurance Practitioners.

Sir Kingsley Wood, on April 11th, asked whether the Minister of Health contemplated any alteration in the terms of payment to doctors on the panel lists; and whether he proposed to consult with representatives of the approved societies on the matter. Mr. Chamberlain replied that before the expiry of the present agreement at the end of this year, both the terms of service and the remuneration of insurance practitioners would have to be reconsidered. In reply to the second part of the question Mr. Chamberlain said that the Insurance Consultative Council had already been consulted in regard to the terms of service, and would be consulted in regard

the rate of remuneration. There was no other body representative of all the approved societies, but he should be prepared to receive representations from the principal groups before coming to a final decision.

Sir Kingsley Wood asked whether Mr. Chamberlain was aware that representatives of the medical profession had declined to meet representatives of approved societies to discuss this matter. Mr. Chamberlain replied in the negative. Major Mackenzie Wood inquired whether the Minister thought that the Council represented the approved societies. Mr. Chamberlain answered that it was an elected body.

Mr. Fairbairn asked whether Mr. Chamberlain would undertake to consult the Insurance Committees in the country, who were representative of all sections. Mr. Chamberlain said that did not arise out of the question.

Sir Kingsley Wood inquired the number of doctors on the panel list, and the approximate annual amount they receive for service. Mr. Chamberlain said the total number of insurance practitioners in England and Wales according to the latest return was 12,588. The total payments to them in 1922 amounted to approximately £6,750,000.

**Indian Universities.**—In reply to Mr. Fisher, on April 11th, Earl Winterton stated that at Dacca a residential university on the lines recommended by the Calcutta University Commission (of which Sir Michael Sadler was chairman) was established in 1921 in pursuance of an act of incorporation passed in the previous year. Owing to financial and other difficulties it had not so far been possible to give effect to the proposals of the Commission in regard to the University of Calcutta, but the complex problems involved were receiving most careful consideration by the Government of Bengal. The recommendations of the Commission had been of the greatest value to the authorities responsible for those Indian Universities which had been reorganized or established for the first time as separate universities since the report of the Commission. This was notably the case in regard to the residential universities of a non-affiliating type established during 1920-22 at Madras and in regard to the University of Madras had been

**Pension Assessments for Bronchitis and Asthma.**—Major Tryon stated, in answer to Mr. Cairns on April 12th, that the approximate number of pensions in payment in respect of affections of the respiratory system (other than tuberculosis) was 41,000. The Minister repudiated the suggestion of Mr. Cairns that medical boards took only two minutes in making an assessment. The average time given to cases of re-examination for renewal of pension was more than a quarter of an hour, and to first claims or for final awards the time given was usually over half an hour.

**Pensions Hospital at Sunderland.**—Major Tryon stated, on April 12th, on a question from Mr. Robert Richardson, that owing to decreasing requirements in the northern region, arrangements had been made to close gradually at Sunderland. This step was under consideration of all the circumstances. The departmental medical advisers would remain to provide without delay all necessary treatment. Mr. Richardson hoped that the Minister would consider the large number of men enlisted from the county of Durham who might want to use the hospital in the near future instead of going as far as Gretna to receive treatment. Major Tryon promised to consider the matter. Mr. Lawson asked if he was aware that for four years the hospitals of Durham and Northumberland had not been able to meet the needs of the civilian population and whether he would further investigate this matter before placing even a small number of military cases upon the civilian hospitals.

**Tuberculosis in Sheffield.**—Asked on April 12th whether his attention had been called to the report of the Sheffield school medical officer, in which he stated that tuberculosis was a very frequent cause of ill health among school children, Mr. Wood said the figures would be reviewed with other similar returns. He was advised they were not representative of the country as a whole.

**Medical Services for School Children.**—Mr. A. Bennett inquired, on April 12th, if the Education Department had informed all education authorities in receipt of public assistance that they must no longer give medical service free to children whose parents were above the poverty line. Mr. Wood, in response, assumed the reference to be to Circular 1300 issued on March 16th last.

#### Answers in Brief.

Major Tryon states out of some 600,000 cases which came up for pension reassessment during 1922, it was found necessary to cancel entitlement to pensions on medical grounds in less than one-half of 1 per cent.

According to Mr. Neville Chamberlain, there were in this country on January 1st approximately 84,000 patients in infirmaries, and in the sick wards of other Poor Law institutions there were 9,800 children boarded out, and 32,000 children in Poor Law institutions provided wholly for the reception and maintenance of children. Women inspectors visited 206 infirmaries last year, and the infirmaries were also inspected by the male general inspectors and by medical officers of the Ministry. The superintending woman inspector was selected from the women inspectors, who required to be fully trained nurses.

## INSULIN AVAILABLE IN THIS COUNTRY.

### CONDITIONS OF SALE AND PRECAUTIONS TO BE OBSERVED.

#### STATEMENT BY MEDICAL RESEARCH COUNCIL.

On November 18th, 1922 (p. 991), we published a statement by the Medical Research Council explaining the measures taken in this country for studying the production and properties of insulin and for promoting its manufacture here upon a commercial scale. On November 4th, 1922 (p. 833), we had published a paper by Professor J. J. R. Macleod, in whose laboratories in the University of Toronto the initial experiments were made, giving an account of the physiological and therapeutic effects of insulin; on January 6th, 1923 (p. 8), we published from the Department of Medicine in the University of Toronto and the Toronto General Hospital a report by Banting, Campbell, and Fletcher recording further clinical experience with insulin in the treatment of diabetes mellitus. On February 24th (p. 341) we published another statement by the Medical Research Council to the effect that insulin was being produced, standardized, and used in the treatment of selected patients at certain hospitals in London, Sheffield, and Edinburgh, and that the Council had entered into agreements with certain manufacturing firms in several parts of the country for the manufacture of insulin, retaining in the public interest control of the safety and potency of the product and its sale at a fair price. No royalties are payable to the Council under any of these agreements. The Council was then able to state that rapid progress was being made and that this was due equally to the laboratory investigations at the National Institute of Medical Research, Hampstead, and to the experience, skill, and enthusiasm which the firms had shown in their co-operation with the Council.

#### British-made Insulin Available on a Commercial Scale.

The Council is now able to announce that British-made insulin is being supplied from two sources—namely, the firm of the British Drug Houses, Ltd., in conjunction for this purpose with Messrs. Allen and Hanburys, and the firm of Messrs. Burroughs, Wellcome and Co. These firms, who undertook the manufacture under agreement with the Medical Research Council, have satisfied all the requirements and tests of the Council for authenticity, standard value, therapeutic efficiency, and sterility of the product sold. It is hoped that these sources of supply will be augmented at an early date by three other firms in different parts of Great Britain who are under similar agreements with the Council.

It should be understood that the rapid progress made by these five firms since the end of last November, and the actual achievement of successful and guaranteed supply within a period of little more than four months from the first attempts at large-scale production, have been made in spite of some serious handicaps. The large quantities of alcohol used for extraction brought the manufacture under almost prohibitive restrictions until certain concessions were made by the Commissioners of Customs and Excise, which allowed specially denatured alcohol to be used duty free. The embargo upon the importation of Canadian cattle had greatly reduced the supply of fresh raw pancreas material in this country, and a good deal of improvisation and initiative has been necessary for the effective organization of the available supply of raw material during recent months. The only limit now placed and likely to be placed for some time upon British production is the limitation of raw material available under suitable conditions.

#### Supplementary American Supply.

In the meantime Messrs. Eli Lilly and Co., of Indianapolis, Indiana, working under agreement with the University of Toronto, have been proceeding towards large-scale production since the early summer of 1922. By the courtesy of the university, this firm was able to submit samples of its insulin product to the Medical Research Council in February last for testing. At the end of March Messrs. Eli Lilly found themselves in a position to offer the Medical Research Council a considerable supply of their product for distribution in this country under similar restrictions to those at present governing distribution during a provisional period in the United States and Canada—namely, to approved hospitals and to physicians with approved clinical facilities. In view of the urgency of the demand, the Council cabled for this supplementary American supply, of which the first consignment is expected

to arrive during the present week. It is a remarkable coincidence that the products of large-scale American production should become available here only a few days after the first commercial supply of British insulin.

The Medical Research Council has arranged that the insulin of American manufacture should be distributed by those British firms whose own product is already available or may hereafter become available, and the amount distributed by each British firm will be in proportion to the volume of its own production. Both British and American insulin will be sold here only under that name (except for the addition of marks or brands indicating origin). A maximum selling price has been fixed by agreement with the Council for a short provisional period, and there is a probability of its being reduced at an early date.

#### *Purification, Potency, and Sterility.*

The British firms have adopted a method of purification of the final product worked out by Dr. Dudley at the National Institute for Medical Research. By this method it is possible to get rid of over 90 per cent. of the solid matter in the crude end-product of the original process, and it allows the manufacturers to offer the active principle in the form of hydrochloride in highly concentrated form, freed from accidental irritants and other substances. For the avoidance of improper exploitation of this valuable process provisional application for patent rights has been filed by Dr. Dudley, jointly with the Medical Research Council. It is probable that in the near future the American supplies will be submitted to the same process and offered in the same form. All the supplies now available have passed suitable laboratory and clinical tests for purity, potency, and sterility.

#### *Dose: Biological Test.*

The physiological unitage originally indicated by the first producers of insulin in the University of Toronto has not been retained. By agreement with the University, the American manufacturing firm has made current in the United States a unit having the approximate value of one-third of the original Toronto unit. The Medical Research Council has decided to adopt this smaller unit, so that all the insulin now made available in this country, whether British or American, will be standardized to a common unit value. Every batch put upon sale, of whatever origin, will be biologically tested under the supervision of the Council, and every preparation sold must bear a number corresponding with that of the batch from which it has been drawn.

#### *Distribution and Sale.*

For a provisional period the Council has retained, under its agreements with the manufacturers, control over the distribution of the commercial supplies analogous to that exercised by the University of Toronto over the products of American manufacture. It is clearly desirable, apart from other considerations, that now, and at least until the supply is more than equal to the demand, the available insulin shall be distributed so as to reach those patients whose need is greatest, and so as to be placed in the hands by which it can be administered to the greatest effect and with the least waste. Difficult problems arise here of interest and importance to the public, to the medical profession, and to hospital administrations.

The research work, both in the laboratory and in the wards, which has brought manufacture in this country to its present pitch, and all the connected problems of standardization and further research work, fall properly within the sphere of the Medical Research Council. These medical administrative problems of distribution, on the other hand, have been submitted by the Council to the Minister of Health, within whose responsibility they properly lie. Having regard to the special nature and urgency of the occasion, the Minister has appointed a small committee to advise him upon the subject, composed as follows: Sir George Newman (Chairman), Dr. R. A. Bolam, Sir Walter Fletcher, Sir Humphry Rolleston, Dr. Alfred Salter, M.P., Dr. McCleary (Secretary) (a dress, Ministry of Health, Whitehall).

#### *Conditions of Supply to Practitioners.*

To avoid any unnecessary delay, provisional authority had been given to the firms to distribute insulin to various large hospitals, and the first British made insulin was actually so supplied on April 12th. On the advice of this committee, manufacturers will be directed, during the present period of restricted production, to supply insulin only to those hospitals and to those registered medical practitioners who have proper

facilities and their command for making accurate blood sugar determinations.

Each hospital and practitioner so supplied will undertake to observe the following restrictions upon the use of insulin:

(1) Careful correlation will be made of the diet, of the blood sugar changes, and of the insulin dosage in each case. For at least one group of cases it is known already that the insulin dosage can be reduced progressively with suitable adjustment of diet. This reduction allows economy of insulin, besides the advantage it may bring to the patient.

(2) Insulin will not be given to those whose symptoms can be controlled by moderate restrictions of diet. There should be no luxury use of insulin till supplies are abundant.

(3) It is understood, of course, that in emergency, and apart from the careful correlation just mentioned, insulin will be given to those in diabetic coma or those nearly approaching it, and it may be given to those with diabetic symptoms needing special preparation for some surgical operation.

(4) Care will be taken to avoid the danger of giving insulin to non-diabetic cases (for example, to patients with renal glycosuria).

Hospitals or practitioners desiring supplies for immediate use should apply to one or other of the British firms named above.

It is hoped that at a very early date preliminary communication will be made of the results of the insulin treatment which has been in progress during the past months in the hospitals at London, Edinburgh, Glasgow, and Sheffield, named in the earlier statement by the Council, in order that the experience gained in this clinical research work may be put at the disposal of the profession for its information and guidance.

#### *Cost.*

The present price of insulin prepared by either of the makers is 2s. 6d. a dose of 10 units, which is the average dose. It is a watery solution and is issued in rubber-capped bottles. The British Drug Houses and Allen and Hanburys, which have worked together, supply bottles containing 10 and 20 average doses (the price of the bottle being 25s. or 50s. respectively). Messrs. Burroughs, Wellcome and Co., who have acted independently, supply the solution in rubber-capped phials containing 100 units—that is to say, 10 average doses. The preparation of each firm fulfils the conditions laid down by the Medical Research Council, as explained above.

## THE LATE DR. A. G. SIMMINS.

### AN APPEAL TO THE PROFESSION.

THE deaths from influenza of Alfred George Simmins, M.B., B.S., aged 32, and his wife, within a few hours of each other, have been chronicled, together with a record of his services to his country and his profession, in the *BRITISH MEDICAL JOURNAL* of April 7th.

He was educated at Guy's and Westminster Hospitals, and at the time of his death held posts of responsibility at the Royal Northern Hospital and the Hospital for Sick Children, Great Ormond Street.

They leave three little children, for only one of whom—a boy of 6—some provision has been made. No funds are available for the education of the other two, a girl and boy, aged 4 years and 15 months respectively, and they are left penniless orphans.

At the time of the catastrophe Simmins was making good, but there was an overdraft at his bank as a result of the purchase of his practice, and he was precluded from the ordinary terms of life insurance by albuminuria, the relic of a previous attack of influenza.

Even in these case hardened days it would be difficult to find a parallel to such a combination of misfortunes, and we are proud to believe that our appeal will evoke a generous response from all branches of the profession. A committee is in process of formation, and several generous donations have already been received. Cheques and postal orders should be sent to the Treasurer, Simmins Appeal Fund, and addressed, Royal Northern Hospital, Holloway Road, N.7.

25 2s.—Mr. A. T. Pitts.

## New South Wales.

[FROM OUR CORRESPONDENT.]

### A PSYCHIATRY CLINIC IN SYDNEY.

For some years past the idea of having a clinic at the Royal Prince Alfred Hospital for early cases of mental disorder has been under consideration. With the advent of Sir John Macpherson as the first professor of psychiatry in the University of Sydney, and the organization of this new department in connexion with the medical school, it has been decided to open an out-patient clinic for the treatment of early mental cases, and Sir John Macpherson is to attend and initiate the work. This clinic will be the first of its kind in connexion with an Australian general hospital, and no doubt it will be of great service in the teaching of medical students. In addition to this clinic at the Royal Prince Alfred Hospital, there is an institution at Broughton Hall, Leichardt, where incipient mental and functional nervous diseases are treated. This hospital contains 100 beds, and patients are admitted without certification. Sir John Macpherson also visits this institution in the capacity of consulting physician. The laboratory of the mental hospitals is at the medical school, which is in close proximity to the Royal Prince Alfred Hospital, so that the clinical and pathological work of the clinic can be well co-ordinated.

### PROPOSAL TO CLOSE A NERVE HOSPITAL.

For several years past the Russell Lea Nerve Hospital has been carried on under the Red Cross Society, and later under the Repatriation Department, as a hospital for cases of nervous and mental weakness among the returned soldiers. Other rest homes and hospitals have been gradually closed down, and the work amongst the returned soldiers has been concentrated at the Prince of Wales's Hospital at Randwick. It was recently proposed to close down Russell Lea also, and transfer the patients to the hospital at Randwick. This proposal has aroused a great deal of comment, and the patients who are at present inmates there, to the number of about forty, have made their wishes known. There is no doubt that this institution is admirably situated; the hospital has large airy wards, a spacious dining hall, with gymnasiums, treatment and recreation rooms; the main building is surrounded by large grounds and is well suited for the treatment of the nervous and depressed soldier. Great stress has been laid on the individual treatment of the patients, and it is said that this could not be carried out at Randwick. In view of the opposition to the proposal it has been decided to defer any action for the present.

### RHODES SCHOLAR FOR 1923.

The Rhodes Scholar from the University of Sydney for 1923 is Mr. R. L. Raymond, who is now in the final year of the medical curriculum, and will graduate next month. This makes the fourth medical Rhodes Scholar from the University of Sydney, Mr. Raymond's predecessors being Drs. H. K. Ward, Howard Bullock, and Granville Waddy. He was educated at the Sydney Grammar School, and after passing his first year in medicine with credit, enlisted for active service, joining the University Company, which, however, was disbanded shortly afterwards on the signing of the armistice. He has passed each of his subsequent examinations with credit. His sporting achievements, mainly on the football field, have been brilliant, and he has entered prominently into the student life of the University.

### UNIVERSITY STUDENTS.

The official figures for the past year show that there were in attendance at lectures 2,965 students, including 706 women. Numerically the medical faculty is still on top, although the number of first year students is declining year by year. The largest years are the present fourth and fifth years, largely due to the fact that these students commenced their course in 1919 and 1920, when the effect of the return of students who had served with the Australian Imperial Force was felt. There are in all 870 students in the Faculty of Medicine, more than 200 above the number in the Faculty of Arts. Only three in the Faculty of Medicine are engaged in post-graduate work.

## Canada.

### CANADIAN MEDICAL ASSOCIATION.

The Canadian Medical Association will hold its annual meeting in Montreal this year from June 12th to 14th. The committee appointed to investigate the advisability of establishing a College of Surgeons in Canada will present its first report at this meeting.

### HONORARY DEGREES.

At the Medical Convocation at McGill University on June 11th honorary degrees will be conferred upon the four following surgeons:

Colonel Sir WILLIAM TAYLOR, K.B.E., because of his distinguished position in the surgical world to-day; his many contributions to surgical literature and the advancement of surgical science; and his service to his country during the great war.

Sir BERKELEY MOYNIHAN, B.C., K.C.M.G., C.B., on the ground of his eminent position as a professional teacher of surgery; his many contributions to the advancement of surgical science, and to the literature of this subject; and his war work as chairman of the Medical Advisory Board.

Sir ROBERT JONES, K.H.E., C.B., in recognition of his position as the foremost orthopaedic surgeon in the Empire; his work in the war as a member of the Advisory Board to the War Office, and a member of the Consultants' Council; and his numerous contributions to surgery, especially military orthopaedic surgery.

Dr. W. J. MAYO, D.Sc., Hon. F.R.C.S. Eng., because of his distinction as a surgeon, his contributions and assistance to medical education and research, and his many contributions to surgical literature.

### INDUSTRIAL MEDICINE.

During the past winter a series of luncheon lectures on industrial medicine was arranged by the governors of McGill University in order to emphasize the value of this important branch of medicine. The complete course was as follows: Industrial medicine, by Dr. B. L. Wyatt, director Laurentide Health Service; Periodic health examination in industry, by Dr. Haven Emerson, Columbia University, New York City; Industrial sanitation, by Dr. George C. Whipple, Harvard University; Industrial health from the standpoint of tuberculosis, by Dr. Linsly Williams, National Tuberculosis Association; The physician in industry, by Dr. W. A. Sawyer, medical director, Eastman Kodak Company.

## Scotland.

### HOSPITALS AND NURSING IN THE HIGHLANDS.

A MEETING, presided over by the Duchess of Atholl, was held last week at Inverness to discuss proposals for co-ordinating the work of the voluntary hospitals in the northern Scottish counties and the relations between the hospitals and various other agencies such as nursing. The attendance was representative of hospital and nursing bodies all over the Highlands. Suggestions were made for the foundation of a federation of the various voluntary institutions, and it was stated that such a scheme had already been carried out in Perthshire. Exceptional difficulties were met in the Highlands, and it was important to further co-operation between the hospitals there in order to safeguard their economic position in the future. The local representatives were instructed to take stock of the position in order to avoid any waste of effort or of bed accommodation, and to consider means of taking joint action when appealing to the public for support. Dr. Simpson (Golspie) said that cottage hospitals might be regarded as casualty clearing stations, but surgical cases which could quite well be treated in them were sent sometimes to the larger hospitals at needless expense. The statement that no scheme of co-operation should be allowed to interfere in any way with the administration of the hospitals by the present administrative bodies was warmly applauded. It was resolved that meetings should be called in Inverness-shire and Ross-shire respectively to discuss hospital co-ordination in these counties.

### HERIOT'S SCHOOL MEMORIAL.

There was unveiled last week in the grounds of George Heriot's School, Edinburgh, a memorial to 470 former pupils who fell in the war. The memorial stands in the centre of

the green slope to the east of the school building and facing the Royal Infirmary; it consists of a graceful column in the form of a Mercat Cross 40 feet high standing on an octagonal stone platform reached by steps. The unveiling ceremony was performed by Lord Provost Hutchison.

#### A MEDICAL DYNASTY.

Dr. A. Maxwell Adams, formerly of Gambia and of Assam, now of Alfreton, Derbyshire, is Dr. Maxwell Adams *quartus*. His great-grandfather, who was (medically) *primus*, lived in Scotland, and not only practised medicine, but also, about eighty years ago, edited a newspaper, and for three years (1847-50) held the non-medical office of chief inspector of poor for the parish of Glasgow, at a time when, after the Irish famine, there was a great influx of Irish from their own land to the West of Scotland, and epidemic typhus and cholera raged almost unchecked. Dr. Adams *primus* did what very few medical men have done either then or now: he kept a regular diary, amounting indeed to an autobiography, and in the columns of a Lanarkshire newspaper his great-grandson has been giving an account of his ancestor's career. Newspaper editing and Poor Law administration were far from sufficient to absorb his energies. He took an active part in a famous succession case in support of an unsuccessful claimant to the Crawford estates and titles in 1828-36. In his Glasgow Poor Law days he waged a constant battle with his local authority, and with the support of the old (at that time the new) Board of Supervision he achieved a great measure of success, winning, incidentally, two lawsuits out of three against the Parochial Board; in the third, though technically defeated, he was complimented by the court on his conduct in a very difficult position, and was not mulcted in expenses. When he had fairly got the better of his nominal superiors, he concluded that he would like an easier life, and they, being glad to get rid of so masterful a servant, acceded to financial terms which met his wishes. Shaking the dust of Glasgow off his feet he resumed practice in Edinburgh, was very successful and spent the last ten years of a strenuous life in comparative affluence and comfort. His present namesake has done well to put on record the story of so interesting and varied a career, and to reproduce it as a neat little pamphlet for private circulation.

## Ireland.

#### SCHOOL MEDICAL INSPECTION.

With reference to the address by Sir James Craig, M.D., to the Teachers' Congress on medical inspection and treatment of school children (see *BRITISH MEDICAL JOURNAL*, April 14th, p. 653), a representative of the *Freeman's Journal* obtained the following statement from the Ministry of Local Government:

"We have read through the paper of Sir James Craig and consider that, generally speaking, it is a very fair statement of the requirements necessary for the development of the public health service. Practically all the matters that have been referred to are at present being examined by the Ministry's experts in these matters, and the Ministry have taken steps to acquaint themselves fully with the conditions of legislation on health matters on the Continent and America. The Ministry share particularly the view of Sir James Craig as to the important rôle to be filled by the county medical officer of health, and consider that the importance of appointing a suitably experienced officer could not be overestimated. As regards the regulations for school medical inspection, these at present include a provision that each committee shall include one manager and one teacher of an elementary school situate in the area of operations. The desirability of close co-operation with the Ministry of Education is fully appreciated, and it is recognized that inspection should be carried out with as little disturbance as possible to the school arrangements. As regards the question of the central authority, it may be observed that the Ministry of Local Government at present includes all the important functions of the Ministry of Health in England. If any further unification is needed it can, no doubt, be easily added in the forthcoming legislation.

"Sir James Craig stated that the Irish people were very far behind any other civilized nation in their attitude and their requirements with regard to public health matters. It is an encouraging reflection, however, that water supplies have been provided for nearly all the important towns. Typhus fever, formerly a great scourge in Ireland, has been practically eliminated, and the mortality from typhoid fever has in recent years been greatly reduced. Within the last four years, when small-pox was prevalent in Glasgow, cases reached Ireland on eleven different occasions, but, owing to supervision at the ports and the effective immediate isolation of

cases, only in one case did the disease spread to a second house. Since the introduction of tuberculosis schemes the mortality from tuberculosis has been reduced from 2.8 per 1,000 to 1.8 per 1,000. Voluntary nursing associations and the activities under maternity and child welfare schemes have reduced infant mortality from above 100 per 1,000 to 85 per 1,000. The Electoral Act and the Local Government (Temporary Provisions) Act have now been passed, and the Minister of Local Government will be enabled to pay attention to the formulation of the Public Health Bill."

## Correspondence.

#### AURICULAR FLUTTER SIMULATING DEATH.

SIR,—In the *Epitome of Current Medical Literature*, par. 302, April 7th, 1923, an account is given of the restoration of two patients whose hearts were said to have stopped beating, and it is stated that they recovered after an intracardiac injection of adrenaline. For a long time I have suspected that in these cases the heart has not really stopped, but has taken on an abnormal rhythm, probably of the nature of auricular flutter. We know that adrenaline is a powerful stimulant, but it must get to the part before it can stimulate it. The mere injection into the heart when standing still would not enable the adrenaline to get to the pace-maker of the heart—that is, the sino-auricular node. That can only be reached by means of the vessels, and in these cases of recovery there can be little doubt that there was still some circulation.

I have the record of a patient who, after running to a train collapsed on getting into the carriage. He was taken out at the next station and laid out in an inn as dead, as the doctor could find no evidence of life. After a couple of hours he recovered. He suffered from other attacks which I recognized as auricular flutter. I was summoned to see him in an attack and this diagnosis was confirmed. In auricular flutter the auricle is beating about 300 a minute, and the ventricle, as a rule, responds only to every second auricular beat, so that usually the pulse rate is one-half the auricular rate. On rare occasions the ventricle may respond to every beat, when the output from the heart is so slight that it cannot be detected by the pulse, while there is an absence of the sounds of the heart.

A classical instance is that of the greatest of clinical observers, John Hunter. Feeling ill, he happened to glance at a mirror and saw his face was very pale. He felt his pulse, and it had gone. He recognized that he was not breathing and had no desire to breathe, so he breathed voluntarily for some time until his pulse was restored. I have always looked upon this as probably a case of auricular flutter.

I think it is Leonard Hill who states that the complete cessation of the circulation for more than one or two minutes irreparably damages the central nervous system, but that the merest trickle of blood is sufficient to prevent this damage.—I am, etc.,

J. MACKENZIE.

St. Andrews, Fife, April 12th.

#### AN OUTBREAK OF RELAPSING FEVER.

SIR,—We wish to place on record an outbreak of relapsing fever observed at Accra during the present month, without for the present entering into the question of its origin.

The first case occurred in an Italian, aged 25, who had been continuously resident in the Gold Coast Colony for two and a half years. He was admitted to hospital with high fever late on March 15th, and very numerous spirochaetes were found in the peripheral blood the next morning. Following close on this case seven others were diagnosed in Africans at the African Hospital. The first of these was admitted comatose and collapsed on March 12th, and diagnosed during a febrile attack a week later. The second was admitted on March 20th, and diagnosed like the first African case a week later. Five more cases occurred, ending with three on March 29th: all these were diagnosed on admittance.

In all cases spirochaetes were demonstrated in the peripheral blood during a febrile attack. The organism corresponds morphologically to *S. duttoni*, and Cox Ingram, at the Medical Research Institute, is carrying out the work necessary to secure the strain. The cases will be recorded at length later.—We are, etc.,

G. E. H. LE FANG, W.A.M.S.,  
A. J. R. O'BRIEN, W.A.M.S.

Accra, March 31st.

## INTRACAPSULAR EXTRACTION OF CATARACT.

SIR,—May I be permitted to correct a slight inadvertence in Lieut.-Colonel Lister's interesting letter (April 7th, p. 612)? The mode of intracapsular extraction selected for the case to which he so generously refers, and in which retro-ocular haemorrhage had to be guarded against, was not Colonel Smith's. That would have been the least suitable since it requires greater pressure upon the globe than any other mode of extraction, and the pressure is followed by rapid relaxation, the effect of which upon brittle blood vessels could not but be dangerous. I have the greatest admiration for Henry Smith's operation in its proper place, and am glad to acknowledge indebtedness for his invaluable teaching, but in my case, cited by Colonel Lister, a different procedure from Smith's was adopted, for the lens was looped out entire by my fine wire loop attached at right angles to a short stem, a mode by which intracapsular extraction is effected without pressure upon the globe.

The case reported was one of four private patients on each of whose remaining eye I practised intracapsular extraction, with good result, after the first eye had been lost, elsewhere, in such good hands that a repetition of the ordinary operation would have presumably invited a similar disaster. The remarkable immunity of intracapsular extraction from post-operative irido-cyclitis makes it, to my mind, the operation of choice whenever the first eye has been lost by anything of that kind, or by needling. After retro-ocular haemorrhage, however, it is not to be recommended, unless, as in the case under consideration, the danger of cyclitis is greater still.—I am, etc.,

ERNEST E. MADDOX, M.D., F.R.C.S. Edin.

Bournemouth, April 11th.

## THE COOLIDGE X-RAY TUBE.

SIR,—I have used the Coolidge type of x-ray tube almost exclusively since the beginning of 1914, and with every satisfaction until recently. I now find that I can no longer depend upon these tubes to carry out the work for which they are designed. It has been the justifiable boast of the makers that these tubes could be so regulated as to give the desired output of a particular type of x-ray. During the past nine months, however, it has been my unfortunate experience to obtain tubes which will not "stand up" against a high voltage current. The reason appears to be that occluded gas is left in the tube which during work becomes hot and so sets free the gas; the tube then takes on some of the characteristics of a "gas" tube, showing green rings around the circumference, and being totally useless for further work until cooled down; even then the same thing happens again as soon as the tube is heated up. This I have found to occur with new tubes and with so called replacement tubes. Previously a standard Coolidge tube would run for one and a half to two hours or longer at a parallel spark-gap of 10 in. and with a current of 10 milliamperes passing through the tube, without causing any trouble or anxiety.

It appears to me that the only way out of the difficulty at present would be to have a certificate from the National Physical Laboratory stating that a particular tube has passed the requisite tests. If all users of these tubes will agree to accept no tube without this certificate, manufacturers will cease to produce anything but the best.—I am, etc.,

W. M. ROBSON, M.D., F.R.C.P. Lond.

Northampton, April 13th.

## VOMITING AFTER DEEP X-RAY THERAPY.

SIR,—The obstinate and most distressing vomiting which so frequently occurs after and often during the prolonged application of deep x-ray therapy, especially when it is applied to the thorax or upper abdomen, has been one of the most trying concomitants of the treatment.

Whatever the cause may be—whether due to direct irritation of the stomach or of the vomiting centre by the changed condition of the blood brought about by the rays—there is obviously gastric irritability, and it seemed to me to be probable that the administration of chloretone would be of benefit. The results, so far, have been satisfactory, and others, practising this form of treatment, may be glad to try it.

I give castor oil the afternoon before the treatment and an enema next morning. The patient takes a light breakfast of tea and toast and butter an hour and a half before coming for treatment, and soon after 10 grains (0.65 gram) of chloretone

is administered. I endeavour to persuade the patient to do without lunch, but, if they feel they must have something, I give a cup of strong soup with a biscuit about 1 p.m.—that is, after about the first three hours—and also I give a further 5 grains of chloretone. About 6 or 7 p.m. a further 5 grains is given, and a drop enema of a solution of the exact saline constitution of the blood. (I have used "normosal," a German preparation, dissolved in the appropriate amount of water.)

Since adopting the above procedure I have treated eight cases:

- One of epithelioma of the larynx (5 hours); no nausea or vomiting.
- One of cervical carcinoma (6 hours); no nausea or vomiting.
- One mediastinal tumour (6 hours); no nausea or vomit ng.
- One malignant prostate (4½ hours); no nausea or vomiting.
- Four scirrhus (7, 6½, 5½, 5½ hours respectively). One patient vomited once during the night after the treatment, the others not at all.

The first case on which I tried the chloretone was one of tumour of the cervical region of the spinal cord, with intense pain. This patient had had morphine and hyoscine for some time before the treatment. I only gave the 10 grains in the morning, and the patient, who had four hours' application of the rays, had no vomiting during the treatment, but did vomit intermittently for two days. Had the chloretone been continued this would not, I believe, have occurred.—I am, etc.,

J. CURTIS WEBB,

Hon. Radiologist, Gloucester Royal Infirmary.

Cheltenham, April 5th.

## THE TRAINING OF NURSES IN COTTAGE HOSPITALS.

SIR,—I would like to draw attention to the training of nurses in cottage hospitals. According to the regulations of the General Nursing Council the teaching and experience of probationers in these institutions is not, and cannot be, recognized for admission to the Register; it is true that there is a clause in the scheme under which two or more small hospitals may work together to furnish the necessary requirements, but under the conditions required this is not, except in very few instances, practicable.

It is unfortunate, for many reasons, that all the training of nurses in our small hospitals should, so far as registration is concerned, be wasted. I have no information of the number of these probationers, but as they serve about 4,000 beds the number must be very considerable. Although they receive no lectures or routine instruction from members of the staff, there can be no doubt that the training is of very real value; it is essentially practical. Their work involves a larger amount of responsibility than is the case in the big hospitals, and allows for a considerable degree of initiative; it is done under the more immediate supervision of the experienced medical staff, who, I feel sure, would confirm my opinion as to the effective value of the teaching.

These hospitals admit probationers at a younger age than the large hospitals; this, I think, is a great advantage—a girl is more teachable at that age, and, although she may then wish to take up nursing as a profession, she may alter her mind if her desire cannot be fulfilled for two or three years. Moreover, if she enters a small hospital, say, when she is 18 or 19, and finds that the work does not suit her or she is not suited to it, she has plenty of time to enter upon some other occupation.

To the cottage hospitals themselves some recognition of their training would be a great assistance, for the difficulty of obtaining probationers has, on account of the conditions now required for getting on the Nurses' Register, become a serious one; if a girl intending to become a nurse knows that two or three years spent at a small hospital will not only fill up the time until she can be admitted to a larger one but will also be counted as part of the three years' training required, she will naturally be more inclined to apprentice herself there than would otherwise be the case.

From the point of view of the larger hospitals themselves the acceptance of this training would mean that there would be a larger recruiting ground from which they could gather nurses; it would, too, provide them with a better opportunity of testing the suitability of and selecting their probationers, who also would be of more use to them than if entirely untrained, and the hospitals would not be troubled as they are at present with so many that are found quite unfitted for the work.—I am, etc.,

Bradford-on-Avon, March 24th.

CHAS. E. S. FLEMING.

## HOSPITAL POLICY.

SIR,—I note that an authority so distinguished and experienced in hospital work as Sir George Beatson<sup>1</sup> commences by expressly defining a voluntary hospital as one "supported by voluntary contributions." Moreover, he insists emphatically upon the necessity of voluntary—by which he means unpaid—service by the honorary staff, despite the fact that in his scheme no less than one-third of the entire expenses of the hospital would be borne by the patients themselves. Clearly, therefore, he has no sympathy whatever with that policy, promoted by Mr. Harman, which would claim for the staff a share in even the smallest individual contribution of the working man. Nor do I picture Sir George adopting the alternative inspiration of that fertile genius, and solemnly demanding of an astonished board of laymen at the Glasgow Western Infirmary that a "token" or "peppercorn" of—shall we say ninnepence?—be for no conceivable purpose or reason annually divided among a staff of fifty-seven.

It is very evident from his letter of April 7th that, although dwelling in Glasgow and profoundly interested in the subject, Sir George Beatson does not even yet the least realize what the policy of Mr. Harman really is. There are many others in a like position. Could any more devastating comment be made upon the notion that this policy was adequately debated in December, 1920, or July, 1921? Plainly in the eyes of Sir George Beatson such a policy as that of Mr. Harman is so repugnant that he cannot imagine anyone would seriously entertain it. Dr. Fleming<sup>2</sup> attributes to me the dictum that, in the extremely unlikely event of the survival of this sickly bantling, which has remained in a condition of suspended animation ever since its premature and precipitate delivery at Newcastle, lay boards must receive payment. Anyone who looks up the reference given in my letter will there discover that Mr. Harman himself took me to task in his most superior manner for venturing to assume that these laymen would, under his revolutionary programme, remain unpaid, and at the same time introduced, in order to illustrate free and uncontrolled volition, that priceless analogy of the British soldier to which I referred.—I am, etc.,

Chichester, April 14th.

G. C. GARRATT.

## ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

SIR,—The kind reference in your issue of March 24th to my questionnaire or skeleton scheme of annual health reports somehow seems to have missed the main point. The principle underlying the scheme may be described by the words "facts reduced to figures, and one figure one line." It was, however, not found feasible to adhere to the formula rigidly. With regard to regulated establishments a separate table is provided for each sanitary district. Further, while meant to be helpful to part-time medical officers of health and individual districts, the system is of most use in the case of a county or combined districts—that is, for compilation purposes—for the query need only be stated once, while the figures for the various districts, being all exactly opposite, can be added up in no time, giving the total for the whole area. The system can be extended to collating the figures for a group of counties—for example, the Welsh group, or the group forming England and Wales, or even larger combinations.

By demanding that every fact (in the form of a figure) should have one line (in a single district), or segment of that line (in a table comprising numerous districts), only facts of sufficient importance to warrant a line will be asked for. There are, however, other advantages, such as the securing of uniformity in presentation, economy in printing (by using stereotype plates), etc., but the proof of the pudding is in the eating, so I shall be pleased to send a copy of annual report for 1921 for a combined area of 20 districts to any medical officer of health on the receipt of six penny stamps to cover postage.—I am, etc.,

E. LLOYD OWEN,

Criccieth, April 10th.

M.O.H. for South Carnarvonshire.

## TREATMENT OF PUERPERAL INFECTIONS.

SIR,—General practitioners like myself must have read Professor Watson's address at Edinburgh (March 24th, p. 505) with a great deal of astonishment. During the last twenty-five years my partners and I have had the care of a very considerable number of cases, and our practice has been never wittingly to allow a piece of placenta to remain in the uterus,

and in case of serious doubt to make a digital exploration, and we have thought that the results have justified this practice. We cannot recall a single case where a piece has been retained and has not given rise to trouble.

Does the professor say that we have been wrong all the time? That we must revise our treatment and, despite our own experience, leave these things to Nature? Again, how large or how small a piece may one leave? Or does it not matter? And when one suspects a retained piece, for how long should one wait for it to come away? (One of us once waited four weeks.) Must the patient stay in bed the whole time? And if the patient should become gravely or fatally ill how should one explain one's inactivity to her friends? Finally, if Professor Watson were looking after the wife of a doctor friend would he himself dare to come downstairs and announce, cheerfully, that he had allowed a piece of placenta to remain in the uterus?

One cannot help wondering whether he has taken fully into account the very large percentage of cases where exploration is done at the time of confinement with a subsequent—I had almost said "consequent"—normal and uneventful puerperium. For in general practice this is the ordinary result even under surprisingly adverse conditions; so much so that one can say that the cases whose puerperium can be expected to give least anxiety are (1) those in whom no vaginal examination whatever has been made, and (2) those in whom the uterus is known to have been left completely empty at the time of the confinement.—I am, etc.,

Penge, S.E., April 10th.

H. H. PHILLIPS.

## ARTIFICIAL LEGS.

SIR,—With reference to the note on the supply of artificial legs, in your issue of March 24th (p. 525), may one be permitted to ask what are the advantages of a "light metal limb" over a "proper wooden leg"?

There are approved artificial legs on the market lighter than "the light metal limb," and the lightest of them all that I have seen is a wooden leg. It is, as are many of the light metal limbs, in point of fact too light for all but a limited number of cases. But the fact that a wooden leg can be made for an above-knee amputation only 4 lb. 2 oz. in weight is a great advance, and it should not be very long before we see a properly balanced artificial limb—one, that is, with a very light foot and ankle and a relatively heavy bucket. We have frequently found that a pensioner in possession of two artificial limbs complains of the weight of one, which upon scaling has proved to be the lighter of the two.

It is to be hoped, therefore, that now that the difficulty of dead weight as applied to artificial legs has been solved by the limb-makers, this question of balance will receive their attention, and it will be an interesting development to watch. The preference for a metal limb would appear to be based on other considerations than these, a discussion of which would be useful.—I am, etc.,

Altrincham, Cheshire, March 21th.

F. A. HOOT.

## INFECTION DURING INCUBATION.

SIR,—Surely it is an established fact that infectivity only begins with the period of invasion.

Once I was able to establish this in the case of mumps. Four pupils slept in one room at a seaside school. A developed mumps and was removed within an hour or two. B, C, and D were isolated in that room. On the twenty-sixth morning thereafter B was taken ill and removed. C and D remained isolated. On the twenty-sixth morning after that C developed the disease and in turn was removed. D did not fall ill and no other cases occurred in that school.

Thus twenty-six days was clearly shown to be the possible duration of the incubation period of mumps, and apparently it was proved that infectivity only began with invasion. I have persistently acted on this presumption in other zymotics and I cannot recall any disasters as the result.—I am, etc.,

London, E.C.

A. OLIVER WARD.

THE Spanish Cross of Commander of the Order of Alphonso XII has been conferred on Dr. Roux and Dr. Petit of the Pasteur Institute of Paris.

THE Congress of the German Dermatological Society will be held in Munich from May 20th to 23rd, when the general pathology, etiology, and treatment of eczema will be discussed. Papers will be read by Drs. Bloch, Kriebisch, Pinkus, and Riecke.

## Obituary.

ARTHUR LATHAM, M.A., M.D. OXON., M.A. CANTAB.,  
F.R.C.P. LOND.,

Physician and Lecturer on Medicine, St. George's Hospital.

WE announce with much regret the death of Dr. Arthur Latham, which occurred on April 13th in a nursing home, after an illness of many months. His loss will be severely felt in several quarters. Latham's opinion on cases of intrathoracic disease, and especially of pulmonary tuberculosis, was highly valued and widely sought, and will be missed by the public and by the profession. The great insurance company to which he was chief medical adviser, St. George's Hospital, and the Federation of Medical and Allied Societies will all feel his loss sorely. The leading part he played in bringing to pass that amalgamation of societies in London which is now represented by the Royal Society of Medicine will never be forgotten. For the first five years of its existence he was honorary secretary to the Society.

At the time of his death Latham held, in addition to the posts alluded to above, those of advisory physician to the Throat Hospital, Golden Square, and to the York Road Lying-in Hospital. In former years he was assistant physician to the Brompton Hospital for Diseases of the Chest, physician to the Mount Vernon Hospital for Consumption, and assistant physician to the Victoria Hospital for Children, Chelsea.

Arthur Latham was born in 1857, his father being the well known physician of Cambridge, Dr. P. W. Latham, who is still alive and active though long retired from practice. The son was sent to school at Fettes College, Edinburgh, where he was recognized as a boy of unusual intelligence, and was also distinguished as a runner and half-back at Rugby football. From school Latham went to Balliol, Oxford, then under the aegis of the great Jowett. His academic career was brilliant; a first class in the final Natural Science Schools was followed by a Radcliffe Travelling-Fellowship, a University Scholarship at St. George's, and a Research Scholarship of the Grocers' Company. During these early years Latham studied at Vienna, Heidelberg, and Berlin, and produced translations of Binz's *Lectures on Pharmacology* and Limbeck's *Pathology of the Blood*. Before his travels he had gained experience of university life at both the ancient English universities. His father at that time held the Downing professorship of medicine at Cambridge, and the son was accordingly entered at a Cambridge college, King's, although already a member of the sister university. Partaking of the education of both places, and meeting early in life the leaders in science at both universities, as well as being surrounded at home by an atmosphere that was both medical and scientific, were advantages that were not wasted on Latham. He imbibed naturally and as a matter of course a large amount of that knowledge which those less fortunately placed gain only by much greater effort. The present writer's earliest recollections of him are at this time, about 1890, at Cambridge, where he seemed to flutter about the work of the students at Addenbrooke's and in the University physiological laboratory like some elegant and interested butterfly that had already culled most of the scent from the fields of knowledge which his contemporaries were laboriously seeking to harvest. Latham always seemed to know more than the rest of us without having obviously learned it. As a matter of fact he was an extremely hard worker at anything which interested him. Gifted, however, with a natural aptitude for detecting essentials he was able to save himself much time which a less intelligent student wastes where it is of little service. Moreover, the natural trend of his mind was scientific, logical, and orderly. In addition, he had an unusual power of rapidly acquiring knowledge, and a good memory.

Latham's hospital career did not disappoint the promise of earlier days, and after holding a house appointment and the post of curator to the museum and demonstrator of pathology he was elected assistant physician to St. George's in 1898. A little later he acted as dean of the medical school for some years. In his early years as a physician he was a close friend of, and was greatly helped and encouraged in his work by, the late Herbert Allingham. It was indeed largely at Allingham's instigation that he entered the competition for a prize offered by King Edward VII for the best essay on the erection of a sanatorium. Gaining the first place in this competition definitely settled the trend of Latham's medical work, brought his name into wide public notice abroad as well as in Great Britain, and may well be regarded as the foundation stone of a success which, nevertheless, all his

friends knew must befall him sooner or later. The way in which Latham worked for that prize was characteristic of his efforts when his interest was aroused by any project. A room in the house where he lived at that time was devoted entirely to the furtherance of his work in the competition. No book or pamphlet that he could bear of or lay hands on that bore directly or indirectly on the subject was absent from this room. Latham gave himself to the work with untiring pertinacity and with the liveliest intelligence. It seemed not so much the writing of an essay as the organization of an exposition of everything that could possibly be worth saying on the subject of the competition. To his friends who understood the method of his work the only surprise would have been his failure to receive the first prize. It was in the same manner and urged by the same fiery spirit of endeavour and determination that in later years Latham did so much to further movements in which he took part. Latham was possessed of qualities which gave him great influence when he took sides in any project or debate. These qualities were courage, initiative, and the gift of lucid and impressive speaking in public. On any committee or like body where Latham served it usually happened that if he formulated a scheme or definitely supported one, that scheme was brought to fruition. It is not possible for a man who had Latham's taste for struggle and argument not to meet with opposition and to make enemies. He did both—without ever losing either his courage in face of difficulties or his inbred courtesy of demeanour in the face of his opponent. His gift for rapidly grasping the essential details of any proposition and for clearly expounding them to others made it seem probable that had the Law instead of Medicine been Latham's choice he would have had at least as great a success. He would have made in many respects an ideal medical member of Parliament. He was greatly interested in the question of the representation of medicine there and it was partly with the view to strengthening this representation and to aiding the present medical members that with one or two others he founded the Federation of Medical and Allied Societies. In his purely professional work Latham was valued as a consultant for the definiteness of his opinion and for his ready reading of character and understanding of human nature. It was through these qualities that many of his patients valued his advice on other as well as on medical matters. Without appearing to be in the least a soft-hearted man he was capable of great attachment, and he performed many acts of charitable kindness to those who needed them. To medical literature Latham's chief contributions were his book on *Early Diagnosis and Modern Treatment of Pulmonary Consumption*, which is in its fourth edition, and a *System of Treatment* which he edited with Mr. (now Sir Crisp) English. Recently he was acutely interested in the relationship between asthma and sensitization to foreign proteins, and was projecting a book on the subject in collaboration with Mr. Frank Coke, and together they had published an account of 270 cases (*Practitioner*, August, 1922). Latham's last illness prevented further work on the book from him.

Some may remember Latham in the future for his cynical comment on or drastic condemnation of their ideas which did not appeal to him. More will remember him for the clear and courageous way in which he upheld movements that he thought right and desirable. Those who knew him well will hold his memory dear for the unselfish devotion which spared and counted no effort where the welfare of those he loved was concerned, for the ready generous and lavish hospitality which he spent upon his friends, and for the zest and sense of humour with which he enjoyed the pleasures and endured the trials of an active life. His was an energetic, aspiring, and restless nature. It was granted to him to achieve much of the great objects at which he aimed, but not to reap the quiet happiness which descends with age on less ambitious spirits.—J. B.

We are indebted to Sir John MacAlister for the following appreciation:

I know that others will be able competently to testify to Dr. Arthur Latham's ability and eminence as a physician, and to his special knowledge of everything relating to pulmonary tuberculosis; but I am glad to be allowed to testify to the valuable work he did for the profession, and for the Royal Society of Medicine in particular in connexion with its amalgamation. Very fortunately for the amalgamation, Sir Richard Douglas Powell, then President of the Society, selected Dr. Latham and Mr. Pendlebury as honorary secretaries of the Organizing Committee literally within a few

days of his receiving my scheme for the amalgamation, and it would be impossible to exaggerate the enthusiasm with which Dr. Latham and his colleagues threw themselves into the work; but neither they, nor even myself, had any idea of the amount of work and worry that this labour would entail—endless committees and innumerable reports occupied over two years of devoted work. They never spared themselves, and I fear often neglected their own professional interests for the sake of the great idea which possessed them. I vividly remember one night (or was it morning?) I had to see them at a critical moment, and, late as it was, found them hard at work on their knees dealing with a mass of papers and reports spread on the floor for easier comparison, as no table was large enough to hold them. Much of the work must have been a tremendous tax on Latham's temper, for points that seemed to be settled were continually being re-raised, until at last he had the satisfaction of having the scheme practically unanimously adopted by the large meeting convened by Sir William Church, Chairman of the Organizing Committee, held in the Royal College of Physicians. But even that did not end his work for the Society. Under its new conditions, when it received the recognition of the late King Edward VII in the form of a supplementary charter, it had to be guided into its new ways; and when the new council, very shrewdly, decided that Dr. Latham and Mr. Pendlebury should be the first honorary secretaries they loyally accepted the duty. Latham's keen brain and zeal proved invaluable, and he stuck to his new post for five years. His tragic and unexpected death makes now impossible what was intended, that he should have received the highest honour within the gift of the Society—namely, to be enrolled as an honorary Fellow of the Society.

JOHN CAMPBELL MACLEAN, M.B., C.M.,  
Surgeon, Victoria Hospital, Swindon.

THE death of Dr. J. Campbell Maclean removes one of the most outstanding practitioners of the West of England. Dr. Maclean was born at Tobermory in the Island of Mull in 1846, and was the son of the Rev. Peter Maclean. He graduated M.B., C.M. at Edinburgh in 1868, and began practice at Swindon in 1869. For forty years he was medical officer for the Swindon and Highworth Union. His sympathy and help were always at the disposal of the poor, and the writer recalls many instances of his gratuitous attention to his old Poor Law patients right up to the end of his career. Of striking and handsome personality, he was to be seen commencing his rounds in an extensive country practice every morning punctually at 9 o'clock, winter and summer alike, and in the London season he journeyed up to town one day every week for the convenience of his county patients. Vigorous in mind and body despite his 77 years, he worked with the spirit of a boy right up to the last, and, although suffering some optical disability after removal of cataract, he availed himself of every opportunity to extend his knowledge and keep himself abreast with the modern developments and technique of clinical medicine. During the pandemic of influenza in 1918, when the medical resources of the town were strained to their uttermost capacity, he cheerfully offered his services to the Great Western Medical Fund Society, and took over a share of their work gratuitously. In recognition of these services he was afterwards presented with a gold watch and chain.

In his younger days Dr. Maclean was an excellent shot, a splendid horseman, and was instrumental in establishing one of the first polo clubs outside Hurlingham. He was a good cricketer, a fisherman, a swimmer, and a yachtsman, but in later years boxing appealed to him most, and he did much locally by his patronage to encourage and foster every form of clean and honest sport. He was singularly modest and unassuming. A charming host and a pleasant companion, he will be remembered by all who enjoyed the privilege of his friendship. A very eminent Freemason, he held Grand Lodge honours in the craft and corresponding rank in the Royal Arch Chapter and Mark Masonry, and in his earlier days he was much in demand at installation ceremonies owing to his knowledge of the work.

Within a week of his death he gave evidence at an inquest and in the evening attended the annual boxing show. On the following day he was suffering from a cold, pneumonia supervened, and, despite the unremitting attention of his colleagues, he passed peacefully away. The funeral took

place on April 6th, in the presence of an immense concourse.

Dr. Maclean celebrated his golden wedding on July 4th, 1921. He is survived by his wife and a daughter.

W. F. J. W.

## Universities and Colleges.

### UNIVERSITY OF CAMBRIDGE.

DR. G. S. GRAHAM SMITH, F.R.S., has been appointed Reader in Preventive Medicine for a period of four years.

The plan for the next final examinations for medical and surgical degrees has now been issued. Part I of the third M.B. examination (surgery, midwifery) begins on June 12th, and ends on June 16th; Part II (principles and practice of physic, pathology and pharmacology) begins on June 13th, and ends on June 20th. The M.Ch. examination will be held on June 12th, 15th, and 16th. The certificates and examination fees of candidates, accompanied by their postal addresses, must reach the Registry by Saturday, May 12th.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY Council was held on April 12th, when Sir Anthony Bowlby, President, was in the chair.

The President reported that the vacancy in the Court of Examiners would be filled at the next meeting of the Council on May 10th.

**Jacksonian Prize.**—This prize for 1922 was awarded to Mr. Sidney Forsdike, F.R.C.S., B.S., M.D., the subject being "The effects produced by radium on living tissues, with special reference to its use in the treatment of malignant disease." The following subject was selected for the Jacksonian Prize for 1924: "The pathology, diagnosis, and treatment of oesophageal obstruction."

Mr. Douglas Gabell was elected a Member of the Board of Examiners in Dental Surgery.

The following Members of twenty years' standing were elected to the Fellowship: John Howard Mummery, Surgeon Vice-Admiral Sir Robert Hill.

Sir Arthur Keith was elected Vicary Lecturer for the ensuing occasion.

### CONJOINT BOARD IN SCOTLAND.

THE following candidates have been approved at the examination indicated:

**FINAL EXAMINATION.**—*Medicine:* H. P. Sen, Wilhelmnia C. Storrer, Ruby S. Beveridge, Eliazar Gelfer, D. G. Contis, Martha D. Devan, M. N. Gelb, G. A. P. McConey, D. B. Nicol. *Surgery:* C. A. Paulusz, M. N. Gelb. *Midwifery:* T. F. Kelly, Ruby S. Beveridge, C. A. Paulusz, W. E. Haydon, Martha D. Devan, G. A. P. McConey, T. J. Muir. *Medical Jurisprudence:* J. A. McCann, J. S. Whiteside, J. McAuley, Anna G. Laubscher, D. M. Safwat, Eliazar Gelfer, H. V. R. McKinlay, A. W. H. Noble, J. Ryan, L. McLean, Mary C. Semple.

The following candidates, having passed the Final Examination, have been admitted L.R.C.P.E., L.R.C.S.E., L.R.F.P. and S.G.:

J. M. McIntock, Minnie E. McMurray, J. M. Cockburn, R. Lal Chopra, N. J. Laubscher, W. N. Strifling, G. A. W. Wickham-Smith, D. Maximos, D. J. Dubash, E. R. C. Walker, P. G. Bainbridge, W. Paris, J. J. du Pre la Roux, J. H. Murrell, S. J. Reich, D. K. Sabhesan, E. Levine, L. Jaffit, J. J. Mann, D. V. Walpole, J. S. Bizzett.

### CONJOINT BOARD IN IRELAND.

THE following candidates have been approved at the examination indicated:

**FINAL PROFESSIONAL.**—T. A. Austin, A. P. Brown, Josephine A. Carson, M. Cremlin, Victoria E. Davidson, Evelyn S. Delany, J. P. Devlin, D. A. T. Eaton, I. J. Eppol, T. V. Fitzpatrick, S. G. Gilmore, A. J. Harte, M. J. O'Riordan, R. D. Scale, V. F. Walsh.

## The Serbires.

### R.A.M.C.—EXAMINATION FOR COMMISSIONS.

THE War Office announces that an examination for not less than twenty commissions in the Royal Army Medical Corps will be held on August 1st, 1923. Applications to compete should be made to the Secretary, War Office, not later than July 23rd. The presence of candidates will be required in London from July 31st. Prospective candidates can obtain a full statement of the duties and emoluments of the service on written application to the Secretary (A.M.D.I.), War Office, Whitehall, S.W.1.

### AUXILIARY R.A.M.C. FUNDS.

THE annual general meeting of the subscribers to the Auxiliary Royal Army Medical Corps Funds will be held at 11, Chancery Street, W.1, on Friday, April 27th, at 4 p.m., when the financial statement for 1922 will be presented and the officers for the ensuing year elected.

### DEATHS IN THE SERVICES.

Brigade Surgeon Edwin Clement Bentley, Royal Medical Service (retired), died suddenly in London on March 22nd, aged 64. He was educated at St. Thomas's Hospital, and took the M.D. in 1853, and the L.R.C.P. Edin. and F.R.C.S. Eng. ten years later. Entering the I.M.S. as assistant surgeon, in the Company days, in

1859, he became surgeon major in 1873, and retired with an honorary step of rank as brigade surgeon in 1885. The whole of his service was passed in civil employ in Lower Bengal, where he held for many years the important civil surgery of Rajshahai. He was the author of a small work on *The Diarrhoea of Infants in India*, published in 1867. Several members of his family have served in the I.M.S.; the late Surgeon Major C. E. W. Bensley was his brother, Colonel C. H. Bensley is his son, and Lieut.-Colonel C. N. Bensley his nephew.

Lieut.-Colonel David C'aude Kemp, I.M.S.(ret.), died of angina on April 3rd, aged 51. He was born on June 8th, 1871, the eldest son of the late D. S. Kemp, F.C.S., and educated at University College, London, taking the diplomas of L.R.C.P.Lond., M.R.C.S. Eng., and L.S.A. in 1896. He went out to India in 1893 as a special plague officer, and entered the I.M.S. as lieutenant on January 28th, 1899, becoming lieutenant-colonel after twenty years' service, and retiring on October 22nd, 1921. Most of his service was spent in civil employ in Madras, where he was for several years resident medical officer of the Madras General Hospital. He served in the late war, and in 1914-15 was specialist in advanced surgery in the Kitchener Hospital for Indian troops at Brighton.

## Medical News.

THE annual meeting of the Royal Medical Benevolent Fund will be held at the Royal College of Physicians, Pall Mall East, S.W., on Monday, May 7th, at 4 p.m., when the annual report and financial statement for 1922 will be presented and the officers and committee for the current year elected.

A COURSE of lectures on pathological research in its relation to medicine has been arranged for the summer session at the Institute of Pathology and Research, St. Mary's Hospital, W.2. The lectures, which will be delivered in the Lecture Room of the Bacteriological Department of the Institute on Thursdays at 5 p.m., commence on April 26th, when Sir Almroth Wright will discuss the principles of medical research. The lectures are open to the medical profession and to all students in medical schools without fee.

It is announced that Sir Charles Brown of Preston has given £800 to the Harris Orphanage, Fulwood, Lancashire, to which he is consulting physician. In offering the gift Sir Charles Brown said that he was prompted to make it during his lifetime by the desire to add to his own happiness by seeing the benefit which will result to the children. The gift will enable the council to purchase a house in Lytham which has been occupied for some seven years as a seaside home for sick and convalescent children of the orphanage.

DR. MILLAIS CULPIN will give a course of ten lectures on psycho-neuroses at the London Hospital Medical College on Tuesdays and Fridays at 5.15 p.m., commencing on May 1st. The fee for admission to the course is £1 1s.

A DISCUSSION on some problems in the lighting of printing works will be held at a meeting of the Illuminating Engineering Society at the house of the Royal Society of Arts on Tuesday, April 24th, at 8 p.m.

AT the meeting of the Tuberculosis Society to be held on Monday, April 23rd, at 8 p.m., at the Margaret Street Hospital, Dr. A. K. Chalmers, M.O.H. for Glasgow, will read a paper on housing and tuberculosis.

A COURSE of six post-graduate lectures on ante-natal care will be given by Professor A. Louise McIlroy at the London (Royal Free Hospital) School of Medicine for Women, Hunter Street, Brunswick Square, W.C.1, on Tuesdays at 5 p.m., commencing on May 1st. Admission is free to medical practitioners and post-graduate students.

THE Association of Public Vaccinators of England and Wales will hold a dinner at the Hotel Cecil, Strand, W.C., on Friday, April 27th, at 6.30 for 7 p.m.

A SPECIAL course of lectures and demonstrations has been arranged by the London University Extension Board and a committee of the International Society of Medical Hydrology. It will be held at the University, in laboratories in London, and at two of the British spas, from May 29th to June 4th. Full particulars will be announced later.

FROM the statement issued by the India Office on April 13th regarding the prevalence of plague in India it appears that during the six weeks ending March 31st there were 48,041 deaths. The mortality was highest in Bihar and Orissa, United Provinces, Punjab, and Delhi. Special measures have been taken to encourage inoculation and rat destruction in Delhi Province, which is administered by the Government of India, and the population of Delhi are reported to be coming forward readily for inoculation.

AT a meeting of the Association of Economic Biologists, to be held in the Botanical Lecture Theatre of the Imperial College of Science, Prince Consort Road, S.W.7, on April 27th, at 2.30 p.m., Dr. C. M. Wenyon will read a paper on some recent observations on pathogenic protozoa of plants and animals.

THE Automobile Association states that its attention has been drawn by the authorities to the insufficient illumination of number plates on motor vehicles. The Regulations do not prescribe the distance from the car or motor cycle at which the index mark and numbers should be readable after lighting up time, but in their own interests all motorists should satisfy themselves that their lighting arrangements are so contrived that—as required by the Regulations—every letter or figure on the illuminated identification plate is rendered "easily distinguishable."

A COURSE of eleven lectures on the management and feeding of infants and young children will be given by Dr. Eric Pritchard to qualified practitioners at the Infants' Hospital, Vincent Square, S.W., on Mondays and Thursdays at 6 p.m., commencing on April 26th. The fee for the course is two guineas, and those participating are entitled to attend the round-table consultations held by Dr. Pritchard at the hospital on Tuesdays and Fridays, and are also afforded opportunities of visiting the Nursery Training School, 3, Wellgarth Road, Golders Green, N.W., and the Home for Blind Babies, Chorley Wood, on Saturday afternoons at 3 o'clock.

PROFESSOR BORDET, director of the Brussels Pasteur Institute, has recently been presented by the King of Sweden with the Grand Order of the Polar Star.

A COMMITTEE has been formed to make arrangements to celebrate the 70th birthday of the well known Italian parasitologist, Professor Battista Grassi, by the establishment of a "Grassi Foundation for the zoological study of parasitic diseases." Subscriptions should be sent to the *Rivista di Biologia*, 27, Via della Dogana, Vecchia, Rome.

DR. NATTAU-LARRIERE, a well known writer on tropical disease, has been nominated professor in the new chair of colonial studies and pathological protistology at the Collège de France.

## Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR OF THE BRITISH MEDICAL JOURNAL, *Aitology*, Westrand, London; telephone, 2630, Gerrard.

2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.

3. MEDICAL SECRETARY, *Medisecra*, Westrand, London; telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Journal is 429, Strand, London, W.C.2.

## QUERIES AND ANSWERS.

### THE NOTATION OF CORRELATION.

"H." writes: In reading reports such as those issued from the Francis Galton Laboratory for National Eugenics, and some of those published by the Medical Research Council on statistical matters, the ordinary reader is puzzled by some of the mathematical formulae used; for instance, in the Medical Research Council's Report on the relation between home conditions and the intelligence of school children, a subject in which many of us would like to take an intelligent interest, such a statement as that the correlation is  $+0.2027 \pm 0.0815$  is encountered. I gather that there is a direct correlation, but as I do not know what unity is my understanding of the statement is vague.

\* \* The subject was fully discussed and explained in an article published in this JOURNAL of July 13th, 1907 (p. 95), and it is not easy to state the facts and theories briefly. It may, however, be said that perhaps the most graphic way of apprehending the idea of a coefficient of correlation is to take the case of two equally variable quantities,  $x$  and  $y$ . Suppose we plot on a diagram the mean values of sets of  $y$ 's associated with particular values of  $x$ , the mean value of  $y$  when  $x$  is equal to 1, the mean value of  $y$  when  $x=2$ , and so on. Then, if the points representing the mean values of  $y$  lie on a horizontal straight line parallel to the base, clearly  $y$  has on the average the same

value whatever  $x$  is; there is no correlation between  $x$  and  $y$ . But if  $y$  increases as  $x$  increases, the line of means slopes upwards to the right; if  $y$  decreases as  $x$  increases it slopes downwards to the right. The coefficient of correlation under these conditions measures the slope of the line; it is positive in the former and negative in the latter case. When it is equal to unity, either  $+1$  or  $-1$ , the correspondence is absolute: for an increase of one unit in  $x$  there will be an increase of one unit in  $y$  absolutely—all the  $y$ 's corresponding to the given  $x$  will be equal—if the correlation is  $+1$ ; if the correlation is  $-1$ , the decrease of  $y$  will also correspond absolutely to the increase of  $x$ . Of course in many cases the mean  $y$ 's corresponding to given  $x$ 's do not lie on a straight line, then the coefficient of correlation ( $r$ ) is not a completely satisfactory measure of the relation. But even in those cases the coefficient gives some idea of the inter-connection, and must always take an arithmetical value lying between 0 and  $\pm 1$ .

The fraction appended to the coefficient after the sign  $\pm$ , is called its "probable error," and measures its reliability, so far as the reliability depends upon the size of the experience—the number of cases examined. Roughly speaking, unless a coefficient is at least two or three times the size of its "probable error" it cannot be regarded as significant.

The other measure of correlation used in the writings mentioned—the correlation ratio, usually represented by the Greek letter  $\eta$ —is designed to measure correlation when the curve of mean  $y$ 's for different values of  $x$  is not approximately a straight line. It also must take an arithmetical value between 0 and  $\pm 1$ , and is to be thought of in the same way—namely, as an arithmetical measure of the closeness of agreement between the variations of the quantities.

#### DILATATION OF CERVIX.

"D. L."—The results of dilatation of the cervix uteri by tents are probably as good as but no better than those of simple dilatation by graduated metal dilators followed by curettage. If tents are used, very careful precautions must be taken with regard to their sterilization. A good method is to leave them for several days in an ethereal solution (1 in 1,000) of mercury perchloride. It may be advantageous to dilate up to 17 or 18 mm. (17 or 18 Hegar) before introducing the tent, and then to introduce two or even three tents, side by side, leaving them in position for twenty-four to forty-eight hours. An anaesthetic is sometimes necessary for their removal.

#### BACTERIOLOGY OF SEA-WATER BATHS.

DR. J. C. MATTHEWS (Liverpool) writes: With reference to the query by "A. G." (p. 666) I beg to call his attention to the article on the "Bacteria of the Water of Public Swimming Baths," by Professor Ernest E. Glynn and J. C. Matthews, in the *Journal of State Medicine* for 1904 (p. 400). I shall be interested to correspond with him.

#### INCOME TAX.

"ALPHA" asks what expenses are allowable, especially in respect of rent and kindred charges.

So far as a house used both for private and professional purposes is concerned a reasonable proportion of all general charges—for example, rent and rates, heating and lighting, cleaning, furniture renewals, etc.—can be deducted; the proportion must depend on the facts of each case. One-third is usually right in a medium-sized provincial town and one-half where the cost of living in a convenient situation is higher; two-thirds would apply to special sites or where an abnormal amount of accommodation is used professionally. The other surgery is a professional matter entirely, seeing that the residential portion is occupied rent-free by the dispenser, and the whole rent is allowable, including the cost of keeping the surgery clean. Other expenses mentioned are allowable; matters not referred to are telephone charges, stamps and stationery, and upkeep—but not improvement—of the equipment of instruments, etc.

#### LETTERS, NOTES, ETC.

##### EPIDEMIC HICCUP.

DR. E. ARCHER-BROWN (Johannesburg) writes: Under this heading in the *BRITISH MEDICAL JOURNAL* of April 7th (p. 603) appears a summary of the pathology of this strange disease, and mention is made of its frequent association with encephalitis lethargica. Last year, whilst engaged in post-graduate study in Philadelphia, I was much interested in an epidemic of this disease which broke out amongst the students at the Evans Dental Institute. In some cases there was hiccup which lasted for weeks, and several deaths were recorded.

Unfortunately I had occasion to visit the Dental Institute as a patient, and a few days later realized that I had become infected. I awakened one night with violent hiccup; this lasted without

intermission for three days and three nights: sleep and the taking of food were impossible, and the violent periodic contractions of the diaphragm at intervals of one to two minutes were extremely painful. I tried morphine but without relief, and then, recalling that for a similar epidemic in South Africa I had used chloretone with success, I took 5-grain capsules of this drug every hour until sleep was induced. On awakening the distressing spasms had ceased.

From my South African experience I should say that hiccup is often associated with epidemic influenza when it is of evil prognosis.

#### VENEREAL DISEASE PUBLICITY.

THE General Secretary of the National Council for Combating Venereal Diseases (102, Dean Street, Oxford Street, W.1) writes: In the synopsis of the London County Council's Public Health Committee's Report (Venereal Diseases Section) in your issue of April 14th the statement occurs that "the Council [L.C.C.] now carries out its publicity work through its own official channels, and the arrangement with the National Council for Combating Venereal Diseases to undertake such work on its behalf has been terminated. . . ." We find that some misunderstanding has arisen owing to this statement. The publicity work referred to in the L.C.C. report is the press publicity; the propaganda work undertaken by the National Council on behalf of the L.C.C. still continues, and the arrangement has been confirmed for the year 1923-24.

#### DISAPPEARANCE OF RODENT ULCER AFTER ERYSIPELAS.

MR. H. FLECKER, F.R.C.S. (Melbourne, Victoria), writes: With reference to Dr. Grant's case of rodent ulcer (January 13th, 1923, p. 82), where operation was refused and which cleared up after an attack of erysipelas, it would be interesting to know whether x-ray or other treatment had been advised. If not, why not? In the *Medical Journal of Australia* for February 24th last is a description by myself of a very extensive involvement of the nasal cartilages which yielded at once to deep x-ray treatment. This is in accord with similar experiences by Moleworth and Harrison, separately described in previous numbers of the same journal. It seems probable that all rodent ulcers, even when involving cartilage, periosteum, or bone will readily yield to x-ray treatment, provided that rays of sufficient penetration and intensity are employed. This last condition is most important.

#### LILLIPUTIAN HALLUCINATIONS.

THE letter from Dr. F. M. Rowland published in the *BRITISH MEDICAL JOURNAL* of November 18th, 1922 (p. 939), has induced Dr. HENRY P. ELLIOT of Cooktown, Queensland, to send us the following note of his own experience.

"Twelve years or so ago, when in practice at Burketown, N.Q., I went down with a pretty severe attack of malaria, with a temperature round 105° to 106°. I was 'teaching' at the time, taking my meals at the hotel. Friends used to drop in during the night and noticed that I always swept my hands over the sheet when I lay down or changed my position. First I had a nightmare of horses jumping over me, but knew that once they had gone the 'little men' would come, and they invariably did. They were jolly little fellows, an inch or so in height, with tin hats like inverted bowls. (Recollections of Java, Singapore?) They were dressed in vivid colours; blue and yellow were always combined, blue hats and yellow dresses, or vice versa, and red and green in the same way. They ran and played about me, but made no noise, reminding me of ants by their apparently purposeless energy. My one concern was that I might not hurt them, and always brushed them aside most carefully before I moved. The secret slipped out later, and I fell in for a considerable amount of chaff; 'tin hats' evidently then having a meaning which only lately I have heard applied to alcoholics."

#### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 34, 35, 38, and 39 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 36 and 37. A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 123.

#### SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	...	...	...
Each additional line	...	...	...
Whole single column (three columns to page)	...	...	...
Half single column	...	...	...
Half page	...	...	...
Whole page	...	...	...

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 61, Strand, London, not later than the first post on Tuesday preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive letters addressed either in initials or numbers.

## An Address

ON

## PANCREATITIS AND ITS ASSOCIATION WITH CHOLECYSTITIS AND GALL STONES.\*

BY

SIR GILBERT BARLING, Bt., C.B., M.B., F.R.C.S.,  
CONSULTING SURGEON, BIRMINGHAM GENERAL HOSPITAL.

It is necessary to recall briefly the anatomy of the parts concerned. The common bile duct and the duct of the pancreas approach each other very obliquely and join in the ampulla of Vater, which opens through the papilla into the second part of the duodenum; a slight sphincteric apparatus surrounds the papilla. It is also necessary to recall that the lower portion of the bile duct is embraced by the head of the pancreas, as is the ampulla; also that the duct of the pancreas is a tube of considerable size, and that there is sometimes a secondary duct of the pancreas of small calibre opening into the duodenum apart from the common orifice with the bile duct.

It has been suggested that fluids may find their way from the duodenum into the bile and pancreatic ducts, but I think this unlikely. If, when the parts are removed at autopsy, the ends of the duodenum be ligatured and the gut filled with coloured fluid, it is not possible by forceful compression of the duodenum to squeeze fluid into the ducts. Important points for remembrance are: that infection may easily spread from the gall bladder down the bile ducts, thence by the pancreatic duct into the pancreas, and that inflammatory processes in the head of the pancreas may compress the ampulla and the terminal portions of the common bile duct and pancreatic duct, producing obstruction to the flow of secretions into the duodenum, causing also some damming of these secretions in the ducts and giving rise to jaundice.

I believe that the dominating factor in practically all cases of pancreatitis is infection from the biliary passages, usually, but not necessarily, associated with gall stones. Thrombosis and other factors, such as the adrenals, may play a part, but the presence of infection is the important matter. It is true that experimental injection of sterile bile into the pancreatic duct may set up an intense pancreatitis, as may the injection of other irritating fluids, but clinically I much doubt if pancreatic inflammation arises in this way. The most favourable circumstance for the regression of bile into the pancreatic duct would appear to be the impaction of a small stone in the lower end of the ampulla, but in four of my cases in which this occurred there was no pancreatitis present. Bearing on the induction of acute pancreatitis two cases of extraordinary interest were published recently.<sup>1</sup> In both cases a round-worm had intruded from the duodenum into the pancreatic duct, setting up in one case an acute haemorrhagic pancreatitis, in the other a less intense condition approximating to the subacute. It is highly probable that the inflammatory condition was induced partly by stasis of pancreatic secretion from the mechanical plugging of the duct, and partly by infective material carried in by the round-worm.

Infection of the biliary passages starts in and from the gall bladder, and is probably an excretory one through the liver. Once infection has arisen it is very difficult to exterminate, even when the gall bladder has been removed and the common duct drained, and one may recall how long-continued infection may be—twenty years or more, for instance, when the organism is the *Bacillus typhosus*.

Pancreatitis may range from an intense fulminating widespread condition which kills in a brief period through a gradually descending scale of intensity to a limited dense patch in the head of the organ, producing symptoms mainly of obstruction to the common duct, difficult to discriminate clinically in some cases from carcinoma, and distinguishable occasionally from carcinoma by microscopic examination only.

It is quite impossible in a brief review to give adequate consideration to these varying and widely divergent pictures presented by pancreatitis. On the survey of a large number of cases of operation for gall stones, it is possible to say that in from 25 to 30 per cent. some degree of pancreatitis is revealed.

## Acute Pancreatitis.

Acute pancreatitis is a surgical emergency with a high but, I do not doubt, a lessening mortality. Never diagnosed in the early days when the condition was first recognized, it is now one of the possibilities always in the mind of the surgeon who is face to face with an acute abdominal emergency which does not conform absolutely to a type, and a correct diagnosis is now made from time to time. In view of the probability that an acute abdominal condition, incompletely diagnosed, requires operative interference, and that acute pancreatitis is one of the things which may be creating the necessity for interference, it is of great importance to secure as accurate a diagnosis as possible, because, whilst in most acute abdominal conditions the time spent in operating should be reduced to a minimum, it is especially true of acute pancreatitis, in which prolonged anaesthesia is very detrimental.

In the diagnosis of acute pancreatitis I should lay great stress on the following clinical points: the pronounced shock of the onset, the severe pain in the back about the lower dorsal region, and usually the localization of the pain and tenderness in the mid-abdomen. Are there any other indications which may help? The presence of glycosuria would, at all events, be suggestive, but it occurs quite infrequently. The diastatic index of the urine should certainly be investigated and Loewi's test should be applied; both, however, should be resorted to as early as possible after the onset of the attack. It is, I think, clear that the diastatic index may be greatly raised in the early hours of the attack and may quickly fall to something like normal. My colleague Dr. Rose tells me that in four recent cases under his care none of the patients had glycosuria, though in two out of three in which the examination was made the diastatic index of the urine was 50.

Dr. Hillier, clinical pathologist at the General Hospital, has been kind enough to make some observations for me in acute abdominal conditions other than pancreatic, to determine whether a raised diastatic index is found in acute conditions not due to the pancreas. He found a normal index in cases of acute appendicitis, strangulated intestine, perforated duodenal ulcer, and so on; in one case of pneumococcal peritonitis the index was as high as 50, but in another similar case it was only 10. The highest index he records was 200 in a case of cholecystitis with perforation of the gall bladder; unfortunately there is no record of the state of the pancreas. My colleague Dr. Russell has been kind enough to place at my disposal a fairly long series of cases of various kinds of diseases in which the state of the diastatic index was investigated. From these no very definite conclusion emerges, but they were practically all cases of chronic disease. What is needed is the estimation of the diastatic index of the urine in all cases of cholecystitis, gall stones, and suspected pancreatitis, and this estimate should be made in the earliest stage of the disease. If this were done, and it takes but a short time to carry out, I believe a real help may be found in a considerably raised index when the pancreas is gravely implicated, and so the most direct and the shortest operative interference would be promoted. Mackenzie Wallis distinctly confirms this view.<sup>2</sup>

What is the fate of a patient who recovers from this grave condition? In the few cases I have been able to follow the patients have had ordinary good health even when masses of pancreatic tissue have been removed. Glycosuria is generally absent in the acute attack, and as far as I can learn does not often follow it. The influence of disease of the pancreas in the production of glycosuria and diabetes is most potent, but I think we must conclude that the islands of Langerhans, or at all events a large proportion of them, escape destruction in acute pancreatitis. I believe this to be true also in the less severe forms of inflammation, for in my own experience glycosuria is uncommon in pancreatitis of the subacute or chronic kind, and if present may be quite transient. We all of us may, when investigating cases requiring operation in which there is no question of gall stones or infection of the pancreas, find moderate glycosuria, and we recognize that other organs may be at fault to explain the failure of metabolism which produces the glycosuria.

Professor Shaw Dunn and Dr. Wynn have placed at my disposal two specimens of diseased pancreas showing that severe destructive changes may occur in the pancreas and yet the islands of Langerhans survive. In the one the pancreatic trouble appears to have begun from calculi in the duct of Wirsung; this was followed by destruction of the whole of the glandular tissue of the pancreas, which is

\* Delivered at the meeting of the Birmingham Branch of the British Medical Association, March 15th, 1923.

replaced by fat, and eventually a malignant growth developed in the middle of the organ. Despite the complete destruction of the gland tissue the islands of Langerhans escaped and can easily be seen in a lantern slide. On only one occasion out of five examinations was sugar found. The second specimen is one of haemachromatosis of the pancreas: the glandular tissue is again badly damaged by fibrosis, but the microscope shows the presence of a large number of the islands; in this case sugar was found *post mortem* in urine in the bladder.

#### *Subacute Pancreatitis.*

I have notes of several cases operated upon for gall stones with subacute inflammation of the pancreas almost merging into the acute form; they differ from the intense cases in that the operations were not emergencies, though enlargement of the pancreas could in some of the cases be determined by palpation; but what led to operation was the diagnosis of gall stones, present in all but one, in which there was only a well marked cholecystitis. Although the diagnosis of gall stones called for operation, features were present in some of these patients with subacute pancreatitis which strongly suggested that the pancreas was involved; in some it could be palpated. The pain complained of in the final attack differed from ordinary gall-stone colic in that it was diffuse, was centred mainly in the mid-abdomen, was persistent, and accompanied by pain in the back in the lower dorsal region; in one patient free fluid was recognized in the abdomen. All of the patients were more seriously ill than those with mere gall-stone colic, in whom there is generally rapid improvement when the acute pain has passed. I note also that there was jaundice in some of the patients and shivering; it is not easy to differentiate between stone in the common duct and infective pancreatitis.

In all the subacute cases of pancreatitis fat necrosis existed—sometimes quite slight, in others extensive; in some a considerable amount of free fluid was found in the peritoneal cavity, slightly brown in colour and with a curious sheen like shot silk; the fluid had a feeble digestive power, and I regard it mainly as a peritoneal exudate provoked by a slight escape of pancreatic secretion into the cavity. In none of these cases was the pancreas incised or otherwise dealt with directly; there seemed no indication, and relief was given only by draining the common bile duct; recovery was usually slow, and I have notes of two cases in which death followed.

In one of these the patient, a man aged 70, upon whom I had operated for stone in the gall bladder, cystic and common ducts (the gall bladder not being removed), there was then no pancreatitis, but the patient afterwards relapsed. At the second operation, eighteen months later, there was no recurrence of stone, but the pancreas was diffusely inflamed and fat necrosis existed. The common duct was drained, but death occurred on the tenth day.

In the other patient, a delicate woman of 60, upon whom I operated for stone in the gall bladder and common duct, the gall bladder was removed; a year later there was severe general pancreatitis, detected by palpation, and slight fat necrosis was found; there was no recurrence of stone. The common duct was drained; a slow convalescence followed, and the patient left the nursing home well and remained so for about two months, when, I am told, the pancreatitis recurred; the organ could be felt very much enlarged, and in a few days part of my incision reopened and purulent stinking fluid escaped. Further operation was refused, and the patient died a few days later, the actual cause of death being described as uraemia with suppression.

For example, my other cases have remained well and, with one exception, free from glycosuria. In the exception there was severe proleucystitis without gall stones and considerable glycosuria for a few days. After operation the sugar disappeared, but three years later sugar again appeared in the urine, and the pancreas appears to be enlarged.

#### *Chronic Pancreatitis.*

In the cases which may be grouped under chronic pancreatitis the disease is usually, though not always, limited to the head, especially to that part which embraces the common duct or ampulla. The condition arises in association either with stone in the gall bladder, in the bile ducts, or in both; but it may undoubtedly exist unassociated with stone and give rise to a train of symptoms indistinguishable clinically from carcinoma of the head of the pancreas, and distinguishable with certainty sometimes, even after the organ has been

exposed, only by microscopic investigation. It is worth bearing in mind that pancreatic calculus may give rise to a limited induration in the head of the organ and be quite as difficult to interpret as those cases in which the biliary apparatus is at fault. One of the real difficulties in operation for stone in the common duct arises from these dense indurations of the pancreatic head obscuring the presence of stone at or near the ampulla; this is the commonest explanation of a stone in the common duct missed at the time of operation. I have just had a vivid reminder of an example of this misfortune in one of my early cases.

I operated in 1904 on a patient for gall stones, found a small contracted gall bladder but no calculi; the gall bladder was excised, and the ducts, which were very patent, were opened and investigated, but no calculus was discovered; there was a small indurated area in the head of the pancreas which I thought explained the persistent jaundice, and as I found that a bougie passed freely from the common duct into the duodenum I concluded that no stone was present, but I was rather uncertain whether the induration in the head of the pancreas was malignant or inflammatory. During convalescence further colic occurred, and I reopened the abdomen and found with great difficulty a small stone in the ampulla.

From this case I learnt one lesson—namely, that a good-sized bougie may pass through the papilla into the duodenum by the side of a calculus in the extreme lower part of the common duct. This reminiscence of the past was brought home to me by the fact that the same patient came to see me for another matter quite recently, when his medical adviser was kind enough to send me all my letters written in 1904.

May I recall yet another mistake, for it is by our mistakes that we learn most?

In a patient who had long been jaundiced and from whom I had removed a single stone in the gall bladder, a very hard mass the size of the thumb existed in the head of the pancreas around the common duct. Fully under the impression that the condition was carcinoma I did cystenterostomy. The patient died from secondary haemorrhage a week later, when necropsy showed that the condition was not malignant but inflammatory.

#### *Yet a third instructive mistake:*

The patient, a male aged 60, deeply jaundiced, wasted, with marked evidence in his stools of failure of pancreatic digestion, with a much distended gall bladder, and a palpable mass in the region of the pancreas, had been diagnosed as suffering from carcinoma of that organ. My own reason for doubting the diagnosis was that the patient had experienced occasionally rather severe attacks of pain almost amounting to colic, and I concluded that exploration was required. At the operation the existence of a distended gall bladder was verified, no stone was found in the gall bladder or bile ducts, but a massive nodular enlargement was felt in the head of the pancreas and was regarded as certainly malignant. The patient died two weeks later, and the necropsy revealed in the middle of the pancreatic mass, quite deep in the surface and about half an inch from the ampulla, a pancreatic stone the size of the tip of the little finger.

If I had incised at the time of the operation I might well have detected this stone, but I was strongly impressed with the belief that the thickening was a growth, and I am always chary of incising the pancreas without very good reason, because of the risk of escape of pancreatic secretion into the abdomen or through the wound, with troublesome digestion of skin, etc. This case is also of interest from the point of view of diagnosis, because it is one of the exceptional cases with deep and persistent jaundice and a largely distended gall bladder not due to malignant disease. If an incision is made in the head of the pancreas great respect should be entertained for the arterial supply through the pancreaticoduodenal vessels. I have seen one fatal duodenal fistula result from the division of these vessels in exploring for stone supposed to exist in a small dense induration in the head.

The last observation I permit myself to add with reference to the condition which occurs not infrequently in jaundiced patients and which is spoken of as catarrhal jaundice and is a result of plugging of the common duct by inspissated bile. I believe the condition which really explains the jaundice is inflammation of the head of the pancreas compressing the common bile duct.

## THE TREATMENT OF DIABETES MELLITUS.

ABSTRACT OF THREE LECTURES GIVEN AT THE  
LONDON HOSPITAL

BY

O. LEYTON, M.D., D.Sc., F.R.C.P.,  
PHYSICIAN TO THE LONDON HOSPITAL.

THE diagnosis and treatment of diabetes mellitus advance rapidly. At comparatively short intervals they need reconsideration. At the present time we recognize that there are some conditions which simulate diabetes mellitus fairly closely and nevertheless may be considered negligible. We also recognize that during the last few years great advances have been made in the original treatment of diabetes mellitus by restricted diet, and that the correct application of present-day methods will arrest the disease in the majority of patients.

No one has been able to frame a satisfactory definition of diabetes mellitus. This is not difficult to understand when we recognize that it, like many other diseases, is a certain deviation from the average and that there is no unanimity as to what is the minimum deviation which is to be termed disease. In order to take an intelligent view on this question an inquiry must be made into the variability of the quantity of dextrose in the urine and in the blood.

Sugar is present in the urine of normal fasting men even when they have not been submitted to any mental or physical strain: the quantity excreted in an hour is in the region of 20 mg., and is not recognizable by the commoner tests for sugar. The quantity of sugar in the urine rises after a meal containing bread and other carbohydrate food, but in all probability this is due to the excretion of unusable sugars and not of dextrose. The administration of 20 grams of dextrose to a fasting man does not lead to any increase in the sugar in the urine, but often 50 grams will do so, raising the excretion to 50 mg. an hour. This slight increase of sugar in the urine, an increase which is not recognizable with Benedict's ordinary qualitative test, has been termed "glycuresis" in contradistinction to "glycosuria." This latter term is reserved for the condition in which a positive result is obtained by one of the ordinary tests for sugar in the urine. The addition of 25 grams of dextrose to every meal may lead to 1.5 grams dextrose being excreted through the kidneys in twenty-four hours. Benedict takes the view that when that quantity is exceeded in the twenty-four hours it is evidence that there is pancreatic insufficiency. His view is far from universal. Some observers state that sugar may be given by the mouth in such quantities as to cause nausea without glycosuria occurring, whilst Woodyat, Sansum, and Wilder injected 63 grams intravenously for four hours (a total of 252 grams) without inducing glycosuria. There is obviously no consensus of opinion on the quantity of sugar causing an abnormal increase of sugar in the urine, although there is an agreement that glycosuria is no sudden event—all gradations occur, from definite glycosuria down to a urine containing 0.002 per cent. For convenience the assumption must be made that glycosuria is present when the urine, mixed with ten volumes of Benedict's qualitative test, reduces the copper on being boiled in a water-bath for six minutes.

The normal quantity of sugar in the blood is no more easily defined than the quantity of sugar in the urine. Every observer should record as many details as possible, although it is probable that some factors still unknown have an influence upon the sugar in the blood. Three main methods of estimating blood sugar are in general use:

**Modifications of Folin and Benedict's Test.**—This is based upon picric acid method, and when heated in alkaline picramic acid. The actual estimation

acid; the blood is deproteinized with tungstic acid, the formed copper solution, and the oxide hour with phosphomolybdic

**Maclean's Method.**—Blood is deproteinized with acid sodium sulphate and dialysed iron; a measured quantity of copper solution containing iodide and iodate is added, the mixture boiled and back-titrated with sodium thiosulphate. Starch is used as an indicator.

The last two methods give similar results, rather lower as a rule than that depending upon picric acid, owing perhaps to the purity of the picric acid not being above suspicion.

The last thousand estimations I have carried out have been with the Folin and Wu method, and 0.2 c.cm. of blood has been taken from the finger; these results influence my judgement, although most of my statements are based upon the observations of others.

The factors determining the sugar in the blood after the ingestion of dextrose are manifold; amongst them the following have been recognized—length of fast previous to administration, emotional condition, rapidity of absorption of dextrose, quantity of dextrose administered, dilution of dextrose.

The quantity of sugar in the blood of the normal fasting man is usually about 0.09 per cent. If 50 grams of dextrose, dissolved in 200 c.cm. of water, be given and the blood taken half an hour later, the percentage of sugar is found to vary from 0.13 to 0.22, but in the majority of cases within ninety minutes it falls below 0.09 per cent.—that is to say, a hypoglycaemia develops. This fall within a definite time and the hypoglycaemia are of greater value in distinguishing the abnormal from the normal than the actual maximum percentage of blood sugar found.

All people do not absorb dextrose at the same rate, and when the motility of the stomach is poor the absorption may be slow, the rise of sugar in the blood slow, and the fall slow; therefore the shape of the curve may not be conclusive; but as a rule even with slow absorption the curve falls because the storing mechanism when started is more than able to cope with the sugar absorbed.

## DEFINITION.

An attempt at a definition may be made now. Diabetes mellitus is a defect in the mechanism the function of which is to store and oxidize carbohydrate, and this makes itself evident by the sugar in the blood becoming excessive.

This sugar seems to be somewhat different from normal blood sugar, as Allen concluded from the fact that dextrose injected into diabetics acted as a diuretic, whilst when injected into normal animals it had no such effect. Quite recently it has been shown that the sugar in the blood of a diabetic possesses a different rotatory value from that in the blood of the normal.

The relation between glycosuria and hyperglycaemia presents many problems. It is true that when the sugar in the blood rises above 0.25 per cent. sugar appears in the urine, and this is not difficult to understand; but sometimes dextrose appears in the urine in comparatively large quantities whilst the sugar in the blood is less than 0.13 per cent. The amount in the blood which just leads to glycosuria is termed the renal threshold for sugar, and is found to vary greatly, not only in different individuals, but in the same individual at different times after food. Based upon my own observations, I should place the average threshold at 0.19 per cent.—the highest 0.23 per cent. and the lowest 0.075 per cent.; but other observers found the range much greater—John states from 0.33 per cent. down to 0.04 per cent.

The height of the threshold is not due to an inherent property in the kidney. Hamburger showed many years ago that the sugar threshold of a frog's kidney could be modified by altering the quantity of sodium bicarbonate in the perfusing fluid, whilst Clarke demonstrated that this was not due to any alteration in the shape of the mesh of the semipermeable membrane of the glomeruli, but to the tubules failing to absorb sugar in certain circumstances. The fall in this power of absorption of the tubules some hours after a meal suggests that the ingredients of the plasma control the threshold. Since we have records of many people who have had sugar in their urine without hyperglycaemia for more than twenty years we must conclude that often this condition is negligible. The fact that occasionally a case of glycosuria develops true diabetes mellitus only leads us to the conclusion that the peculiarity does not protect from diabetes mellitus. Perhaps an appropriate simile exists in the fact that alkaptonuria does not protect from carboluria, but makes the diagnosis a little less simple, just as a low threshold complicates the diagnosis of diabetes mellitus.

## DIAGNOSIS.

The differential diagnosis between glycosuria without hyperglycaemia and diabetes mellitus is as a rule quite simple, but in doubtful cases laborious. It is my duty, however, to emphasize the fact that no case of glycosuria should be considered negligible until the medical man responsible for its treatment is convinced that his patient is not suffering from diabetes mellitus. The restriction of diet does little harm to

a case of negligible glycosuria, whilst an unlimited diet does incalculable and irremediable damage to a true diabetic.

The method I adopt in doubtful cases is the following: The patient has a sample of blood taken and empties the bladder. He is then given a known quantity of dextrose, the amount depending upon the likelihood of his having diabetes mellitus—the less the probability the larger the dose. Blood samples are taken at intervals of ten minutes and urine samples at intervals of a quarter of an hour for two hours. In the majority of typical cases a striking phenomenon is noted—namely, that the percentage of sugar in the urine rises after the sugar in the blood has started falling. This great delay in the maximum glycosuria seems typical (Chart 1). The hypoglycaemia which follows within ninety

minutes of the ingestion of the sugar rules out diabetes mellitus (Chart 2). It is the border-line case which is difficult

(fall of blood sugar delayed, glycosuria almost coincident with hyperglycaemia, diuresis accompanies hyperglycaemia), and occasionally, as in the case illustrated, the only method of arriving at a conclusion is by leaving the patient upon an ordinary diet and re-examining after an interval of a few months.

Glycosuria with hyperglycaemia arises from other causes than pancreatic inefficiency; it may be due to hyperthyroidism, overactivity of the suprarenals, disease of the pituitary gland, irritation of parts of the central nervous system, and perhaps to certain changes in the liver.

The differential diagnosis may need the use of all the methods at our disposal. Slight hyperthyroidism rarely leads to glycosuria with hyperglycaemia; considerable overactivity of the thyroid increases the basal metabolism and is usually associated with tachycardia, fine tremor, and a moist skin, three signs which do not arise from pancreatic insufficiency. Overactivity of the suprarenal glands may arise from anxiety; usually an increased blood pressure can be demonstrated; this when present does not permit true diabetes being excluded. As far as I am aware, ketosis and a low respiratory quotient do not accompany glycosuria of suprarenal origin.

In disease of the pituitary gland the glycosuria is often intermittent; the relation between sugar tolerance and

changes in the gland is not easy to understand. In some cases of pituitary tumour the sugar tolerance is low, whilst the patient responds well to treatment by restricted diet; in others the sugar tolerance is above the normal. A radiograph of the skull assists diagnosis. The differential diagnosis between pancreatic and hepatic disease may be made by estimating the sugar in the blood after the injection of insulin, or some pancreatic extract which replaces the substance made by the islands of Langerhans. A fall in the sugar indicates that the hyperglycaemia was pancreatic in origin; no distinct change will point to the liver being at fault.

In the past Cammidge has found that the ratio of two substances in the blood—one dextrose, the other a substance which can be hydrolysed into a sugar—is not the same at varying times after food in hepatic and pancreatic disease. Space does not permit my giving details. The fact that insulin by itself does not change  $\alpha, \beta$  glucose into  $\gamma$  glucose without the presence of hepatic extract seems to point towards the possibility of the existence of hepatic glycosuria.<sup>2</sup>

Having arrived at the diagnosis of pancreatic diabetes the patient should be examined with great care to discover any focus of infection. The gums, alveoli, tonsils, antrum, lungs, skin, and urinary tract should receive special attention. Any focus should be dealt with immediately unless a general anaesthetic is an absolute necessity. Local anaesthetics and intraspinal anaesthesia do but little harm, but chloroform, ether, and nitrous oxide should be avoided, because they may, and often do, cause destruction of some of the cells of the pancreas which are still doing some work. In all probability nitrous oxide with 20 per cent. oxygen would prove of but little harm, but since real relaxation can be obtained only when the mixture is administered under pressure we must wait until a philanthropist will supply the funds for a theatre which will withstand an extra half-atmosphere pressure.

The treatment of the patient should not be delayed; often every day is of value. The object of the treatment is to reduce the sugar in the blood to 0.10 per cent. without producing a ketosis or increasing an already existing ketosis; then to find a diet which will not cause the sugar in the blood to rise above 0.15 per cent. at any time.

The only way to arrest the progress of the disease is by ceasing to overwork the pancreas. We have reason to believe that certain forms of glucose in the blood stimulate the pancreas, and if these be present in excess overstimulation which results in progressive deterioration is inevitable. It is true that not every case of diabetes mellitus can be arrested; some are too advanced when they come under treatment; the lives of these must depend upon a supply of insulin. Cases treated correctly may go downhill owing to events against which we do not know how to guard our patients. A patient which may have a second or even a third attack of diabetes mellitus; because he has had one or two he is not immune from further invasions. We are not acquainted with the nature of the toxin which destroys the cells of the islands; the fact that occasionally slight pyrexia accompanies the onset suggests that it may be of microbic origin, but this slight pyrexia is the exception rather than the rule.

The second attack may occur whilst the patient is on a diet which has prevented blood sugar rising above 0.15 per cent. during the previous months or even years; in all respects it simulates the first attack. The symptoms are sudden thirst, polyuria, and glycosuria; these are totally different from those occurring in the cases incorrectly treated when the alteration is insidious, the tolerance gradually diminishing and the glycosuria slowly becoming more frequent.

Another event against which we cannot guard our patients is infection: influenza, pneumonia, whooping-cough, chicken-pox, etc. I have seen all these lead to such deterioration in the pancreases of arrested cases that upon re-estimation the tolerance of the patient I have found that a decision had to be made between death from inanition or ketosis. It is of interest to note that often in these infections the return of glycosuria occurs before the signs and symptoms of the disease are manifest or before the temperature rises. This is not difficult to understand when we remember that the injection of a few million dead microbes into a diabetic will cause a temporary hyperglycaemia.

A third event which may cause advance of the disease is a general anaesthetic, and circumstances may arise which leave no choice—such as malignant disease requiring a large first lumbar segment.

## TREATMENT.

The treatment of the patient should depend upon his age, condition, duration of the disease, and severity of the symptoms. For the purpose of describing the treatment patients may be divided roughly into three groups: (1) Recent acute onset. (2) Acute onset some years ago, or chronic disease of onset. (3) Mild cases, obese but losing weight, often with signs of arteriosclerosis.

Patients belonging to Group 1 should be put to bed and placed upon a beef-tea diet straight away. The risk of ketosis is negligible in quite recent cases. The blood sugar should be estimated after forty-eight hours' fast even if glycosuria persists. I have met at least four cases of true diabetes mellitus with low renal thresholds; glycosuria persisted in these after the blood sugar was normal (0.10 per cent.), and they might have been fasted indefinitely if an attempt had been made to abolish the glycosuria.

If the blood sugar is normal the patient is given 10 grams of carbohydrate in the form of vegetables for two days, and on the third day the blood is taken at intervals after a meal containing 5 grams of carbohydrate given as white bread. If the blood sugar does not at any time rise above 0.14 per cent., the daily diet is raised to carbohydrate 15 grams, with the addition of 15 grams of protein and 15 grams of fat.

After an interval of two more days blood samples are taken following a meal of carbohydrate 10 grams, protein 10 grams, fat 10 grams (carbohydrate given as bread); if satisfactory, the daily diet is raised to carbohydrate, protein, fat, 30 grams of each, and after two days the effect of a meal of 15 grams of each is observed. Provided no hyperglycaemia follows, the diet is raised to carbohydrate, protein, fat, 45 grams of each, for the next two days; then a meal of 20 grams of each is given, and if that is well borne the daily diet is raised to 60 grams of each.

No advance is then made in carbohydrate or protein, but fat is increased 20 grams daily, until the patient is receiving 25 calories per kilogram body weight, provided no ketosis occurs. This allows a suitable diet to be found. The patient should have the blood examined every few days to see that the blood sugar does not rise above 0.15 per cent., and remain upon 25 calories per kilogram for at least a month. After that time the effect of slight increases in carbohydrate may be observed. Undernutrition for a considerable period is advisable, even if the blood sugar remains low, the rationale being that the maximum recovery of the pancreas will occur if it be given the minimum work with the best blood supply.

Fasting may rest the pancreas, but a very long fast probably interferes with its nutrition; we must attempt to steer a course between the Scylla of overwork and the Charybdis of starving the pancreas. The patient may be allowed up after the second week of treatment. Free purging with magnesium sulphate during the first few days of treatment is beneficial to the patient.

If the blood sugar be found to rise above 0.15 per cent. before so liberal a diet be attained an attempt must be made to decide which of the kinds of food is responsible. Now and then we come across patients who are able to take more carbohydrate than fat, although the reverse is the more common. Those who have not met these cases may feel inclined to attribute this to the fact that the energy value of fat is more than double that of carbohydrate, and that it is simply due to the general tolerance of the patient being very low; this is, however, not the explanation, because some can take more energy in the form of carbohydrate than in the form of fat.

This fact confirms the view I have taken for some years, that although the general build and main chemical changes in all men are similar, the differences in their metabolism are not less than the differences in their personal appearance.

The emaciated patient with ketosis must have preliminary treatment before fasting. The fat should be removed from his diet immediately, and after two days of very limited protein and carbohydrate fasting should be ordered for two days. If the blood sugar does not fall to normal in that time two days of a diet of carbohydrate 10 grams, protein 20 grams, should be given, and then the effect of two more fast days observed. Yet a third fast may be tried if the second does not accomplish the desired result. In case the third fast proves unsuccessful the patient should be carefully re-examined for some focus of infection; if none be found a meagre diet of carbohydrate 10 grams, protein 30 grams, fat 20 grams, may be given for fourteen days, and then another attempt should be made to reduce the patient's blood

to normal. When the blood sugar has been normal for twenty-four hours the effect of food is determined in the same way as in the essay on the recent cases. As a rule the tolerance is found to be very low.

The mild cases need not be fasted: a restricted diet reduces the blood sugar to normal. The obese patients are given very little fat until they have burnt the excess in their bodies. The diet is controlled by frequent estimations of the sugar in the blood.

It is an unfortunate fact that at present the work entailed is considerable, because the time after a meal at which the sugar in the blood rises to the maximum is not constant. Obviously it will depend not only upon the type of carbohydrate given, but also upon what food is given along with the carbohydrate. Samples should be taken every quarter of an hour, beginning half an hour after the meal, for one and a half hours. This need be done only when the final diet is being reached.

Perhaps if the blood sugar can only occasionally be estimated it is wiser to make an attempt to find the diet that will just allow the threshold being exceeded, and then arrange a permanent diet which is two-thirds that amount. For this purpose the daily examination of the urine for sugar is useless and most misleading. The urine must be passed at intervals after a meal which should contain five-twelfths of the daily diet. Each specimen should be examined separately. Often the twenty-four hour sample will not contain sufficient sugar to give a positive reaction, whilst several separate specimens show that the threshold has been exceeded for a short time after the meal.

Having determined the correct diet, the patient is told to test the urine from time to time, but on no account to increase the diet, even if there be no sugar. The object of the treatment is not to abolish glycosuria but to arrest the disease. Sherrill has recorded cases in which he has observed that patients whose tolerance has deteriorated whilst on a diet which prevented glycosuria may have the disease arrested by regulating the diet by the sugar content of their blood. I, too, have had many similar cases.

*Treatment by Insulin.*

How far insulin will modify the treatment of diabetes mellitus is not easily foretold. There is very little doubt that it will prolong the lives of those patients who have only a very small fraction of the islands of Langerhans functioning. The history of insulin is fairly well known; I regret that space will not permit me to give details, but only to express my admiration of the work of Banting, Macleod, and their fellow workers. The substance termed "insulin," obtained by fractional alcoholic precipitation, seems to be something other than a ferment, and does not give the protein reaction. That it supplies the substance which the diabetic does not make seems beyond doubt. The diabetic fails to store sugar, as shown by the blood sugar becoming excessive; he fails to burn sugar, as shown by his respiratory quotient being too low. The injection of insulin into a severe diabetic lowers his blood sugar and raises his respiratory quotient.

How it acts needs investigation, but it has been shown that the sugars in the blood of diabetics are not the same as those in the normal individual, and that the abnormal sugars can be converted into the normal by the action of insulin along with hepatic extract.

Insulin is not upon the market in Great Britain,\* although it is procurable in other countries. The dangers of its use are not, in my opinion, fully realized at the moment. An overdose may lead to convulsions, coma, and death; but, since the introduction of a little dextrose acts as a complete and rapid antidote, that danger seems to be almost negligible, provided that everyone into whose hands insulin finds its way is made acquainted with the facts. In my opinion the danger lies in the administration of limited insulin and unlimited food. The simile between the treatment of diabetes mellitus with insulin and of myxoedema with thyroid extract is inopportune. No doubt the activity of the thyroid waxes and wanes as necessity arises, and the individual taking thyroid, however carefully the dose be regulated, is not so well as he who has a normally active thyroid. The variations in the activity of the pancreas in all probability are many hundredfold the variations in the thyroid; the activity seems to be governed by the sugar in the blood, which in turn depends upon the carbohydrate in the food.

\* Since this was written insulin has been placed upon the market and one has had opportunity of confirming the beneficial effects recorded by others.

Man can live fairly comfortably on 30 grams of carbohydrate along with unlimited protein and fat. If a case of severe diabetes be given enough insulin to ensure his utilizing 30 grams of carbohydrate he will escape the symptoms of diabetes mellitus, but his blood sugar will be above 0.15 per cent. during the greater part of the twenty-four hours, which will cause overstimulation of the small amount of pancreas which he still possesses and gradual deterioration. The final stage will be total destruction of the pancreas; then the patient will have to rely for all the sugar-burning material on supplies from the outside. In case these fail, life would be extremely short. This is the danger which should be avoided by strictly correlating the diet with the amount of insulin available from the pancreas of the patient together with that injected.

## OBSERVATIONS ON THE INFLUENCE OF INSULIN ON NORMAL METABOLISM IN MAN.

BY

C. H. KELLAWAY, M.D., M.S., M.R.C.P.,

FOULERTON STUDENT OF THE ROYAL SOCIETY.

AND

T. A. HUGHES, M.B., B.Ch., M.R.C.P., MAJOR I.M.S.

(From the Medical Unit, University College Hospital Medical School.)

THE study of the respiratory exchange in diabetic patients and in depancreatized dogs by Banting and his co-workers<sup>1</sup> has shown that the injection of insulin, either alone or combined with the administration of sugar by the mouth, causes a pronounced rise in the respiratory quotient. This rise has been generally interpreted as indicating increased consumption of glucose, the ability to burn carbohydrate being temporarily restored by the action of insulin. Dudley, Laidlaw, Trevan, and Boock<sup>2</sup> have recently failed to find any direct evidence of such an action of insulin in normal mice and rabbits, the diminution of circulating sugar being attended by a profound fall in both oxygen consumption and output of carbon dioxide, although they observed in some experiments a marked rise in the respiratory quotient which evidently could not be attributed to increased combustion of glucose.

So far as we are aware, no observations on the influence of insulin on normal metabolism in man have been recorded, and it seemed worth while to record two such experiments, which Miss M—, a medical graduate, very kindly allowed us to make upon her. We made three series of observations, and on each occasion the subject had no food and only water to drink for the preceding fifteen hours, and during the experiment. She was kept at rest in a bed which was screened off in a corner of a ward. A number of six-minute samples of expired air were collected in a Douglas bag at approximately hourly intervals, some before and some after the injection of insulin. Before the collection of each sample the subject breathed for five minutes through the mouthpiece containing inspiratory and expiratory valves, in order to ensure respiratory equilibrium. Observations of the pulse and respirations were made during this period and during the collection of the sample. A half-hourly record of the rectal temperature was kept throughout the day of each experiment.

The insulin used in these experiments was made under Professor Drummond's direction in the Biochemical Department at University College, and was tested for us by Dr. Babkin. We have expressed the dose used in multiples of the amount required to reduce the blood sugar of a rabbit weighing 2 kilos sufficiently to cause convulsions. The injections were made subcutaneously, and changes in the blood sugar were followed, using Maclean's method for 0.2 c.cm. of blood.<sup>3</sup>

A preliminary experiment in which we took a series of eight samples of expired air, four before and four after the injection of two rabbit doses of insulin, gave the subject the necessary training in breathing and furnished an indication of the amount of insulin which could be used in our later experiments. The fall of blood sugar in four hours after this dose of insulin was from 0.123 per cent. to 0.108 per cent., and there were no significant changes in the metabolism. We give condensed protocols of our two subsequent series of observations.

In both these experiments there was a marked rise in the respiratory quotient associated with the fall in blood sugar

caused by insulin. In Experiment 2 the blood sugar fell from 0.125 per cent. to 0.080 per cent. in one and a quarter hours, and, allowing a quarter of an hour for insulin to be absorbed in sufficient amount to affect the blood sugar, there was a fall of 0.045 per cent. in an hour. If we assume, with Keith, Rowntree, and Geraghty,<sup>4</sup> that the blood volume in man is 85 c.cm. per kilo of body weight, this represents a loss of  $0.045 \times 76 \times 85 = 2.9$  grams of glucose. This is a conservative estimate of the amount of sugar lost from the blood, because the low level of blood sugar was maintained at 0.080 per cent. for the succeeding two hours, which suggests the attainment of an equilibrium between the sugar disposed of by insulin and that which is in all probability mobilized from the liver during the time of its action.

What is the fate of this sugar lost from the blood? Is it consumed, transformed to glycogen and stored in the liver and muscles, or is it transformed to some other complex, such as fat? If it is stored as glycogen, we are left without any

At 12.30 ten rabbit doses of insulin were administered. There was a definite increase in the ventilation rate one and a quarter hours later, but the patient showed no symptoms till 2.30 p.m., when she commenced to perspire freely. At 2.45 she complained that her voices were unduly loud and that she was feeling dizzy. The drowsiness increased, "coming and going in waves," as she said. The mental condition became very striking. The blood pressure was normal and there were no neurological signs. At 4 p.m. 50 grams of glucose were given and the symptoms rapidly disappeared.

Fig. 2—The effect of eight rabbit doses of insulin on the same subject as Fig. 1. Calories per hour calculated as in Fig. 1.

At 11.15 a.m. eight rabbit doses of insulin were given. There were no symptoms, though the pulse and respiration rate rose slightly, except a subjective sensation of warmth soon after the injection, and a tendency to perspire at about 2 p.m.

explanation of the pronounced rise in the respiratory quotient. We are therefore confined in our consideration to the first and last possibilities. Let us examine the first of these and assume that the glucose is consumed under the influence of insulin.

The combustion of 2.9 grams of glucose would require 2.158 litres of oxygen, and would result in the liberation of a corresponding amount of carbon dioxide, since 1 gram-molecule (= 180 grams) requires for its complete combustion 6 gram-molecules of oxygen, or  $6 \times 22.33$  litres at standard temperature and pressure, according to the equation—

If the glucose lost from the blood were burnt the rise in oxygen consumption per minute should average 36 c.cm. during the hour of the fall. Actually, the increased consumption of carbohydrate would raise the basal metabolic rate of a starving person and cause a still greater increase in the amount of oxygen used. In this experiment there was no significant rise in the amount of oxygen used, and this, together with the rise of over 30 c.cm. in the output of carbon dioxide a minute, suggests that the combustion of glucose plays only a minor part in the production of the high respiratory quotient, and that the principal factor in causing this change is the transformation of carbohydrate to some other complex, with economy of oxygen and liberation of excess of carbon dioxide. The metabolism in calories per hour is calculated in these experiments on the assumption that the rise in respiratory quotient is due to the com-

bustion of additional carbohydrate, allowing a larger production of heat from a given oxygen consumption at a higher respiratory quotient. Even on this assumption, which we believe to be unsound, the greatest increase in metabolism calculated from the observed oxygen consumption and respiratory quotient—namely, 1.3 calories an hour—does not correspond with that calculated from the combustion of the amount of sugar lost from the blood—namely,  $2.9 \times 4.1$  calories = 11.89 calories.

In Experiment 3, in which we gave a smaller dose of insulin, the results do not indicate so clearly the nature of the increase in respiratory quotient. The sugar lost from the blood in two and three-quarter hours was  $0.053 \times 76 \times 85 = 3.42$  grams. The amount of oxygen

necessary for the combustion of this amount of sugar is 2.530 litres, or an average of 24 c.cm. a minute. Although the observed increase in the oxygen consumption does not attain to this calculated value, it affords definite evidence of the combustion of glucose. The disproportion between the observed increase in oxygen used—that is, 2,120 c.cm. (g.p.)—and that in carbon dioxide given out—that is, 3,193 c.cm. in two and three-quarter hours—supports our contention that the rise in respiratory quotient is due in part at least to transformation of glucose into some complex poorer in oxygen, and that the metabolic rate as calculated from the oxygen used and the respiratory quotient is much above its real value.

## SOME PROBLEMS OF DIABETES MELLITUS.\*

BY

L. B. WINTER AND W. SMITH.

(From the Biochemical Laboratory, Cambridge.)

NEARLY forty years ago Mering and Minkowski showed that complete removal of the pancreas resulted in a condition of diabetes. Numerous attempts have since been made to prevent the diabetes following on depancreatization by injection of extracts of pancreas. No real success resulted until the great advance made by Banting and Best. It was found that if the acinous tissue of the pancreas was allowed to degenerate after tying of the duct, an aqueous extract of the gland would diminish the excretion of sugar when injected into depancreatized dogs. This tended to explain the failure of previous workers. Presumably the active principle of the islets of Langerhans, which they termed "insulin," was destroyed by some secretion of the acinous tissue.

The discovery, due to Collip,<sup>1</sup> that an alcoholic extract of normal pancreas is effective, has made possible an extensive trial of the effect of insulin on diabetes in man.<sup>2</sup> These workers have treated a large number of cases, with successful results. They establish beyond doubt that injection of insulin, in the majority of cases, stops the excretion of sugar and acetone, and enables the patient to utilize an increased amount of carbohydrate.

The action of the pancreas on carbohydrate metabolism has been the subject of much study. The work of Cohnheim suggested that the pancreatic secretion caused an increased consumption of glucose by the muscles. Levene and Mayer,<sup>3</sup> found, however, that the disappearance of glucose was due to the formation of a disaccharide, and that this formation took place only in concentrated solutions of glucose. If the solution was diluted the disaccharide was hydrolysed, and the reducing power showed that the glucose concentration was the same as at the beginning of the experiment. Though it is difficult to determine the precise bearing of these results on diabetes, they tend to show that the action of the pancreas is to activate some enzyme system—for the addition of pancreas or muscle extract alone to glucose was without effect; only when muscle and pancreas were acting together was any effect observed. Clark<sup>4</sup> showed that the consumption of sugar by the heart was increased when the perfusing fluid was also passed through the pancreas. In a later paper<sup>5</sup> he established the remarkable fact that perfusion of the pancreas

\* Since this was written there has appeared an article by Hewitt (*BRITISH MEDICAL JOURNAL*, April 7th, 1923, pp. 550-591) criticizing some of this work. We propose to reply in detail in the near future.

with a solution containing glucose caused the optical rotation to be diminished, whereas the copper reducing value remained unaltered. He suggested that the pancreas contained an enzyme which was responsible for converting dextrose into another form of sugar, which then could be utilized by the body.

The precursor of lactic acid in muscle has been investigated during recent years by Embden and his co-workers.<sup>6</sup> They have shown that liberation of phosphoric acid accompanies the setting free of lactic acid. We have shown that when muscle is put into rigor the increase of inorganic phosphate may be demonstrated histologically.<sup>7</sup> Embden has isolated from muscle an osazone which is identical with that of the hexose-diphosphoric acid compound obtained from yeast by Harden and Young. While it is uncertain whether the lactic acid precursor or "lactacidogen" is a hexose-phosphate, they consider that such a compound is certainly a component of the molecule which gives rise to lactic acid. Added hexose-phosphate was readily broken down by muscle juice with liberation of lactic and phosphoric acids; added glucose was not converted into lactic acid. Harden showed that the hexose-diphosphate which he obtained from yeast yielded fructose on hydrolysis. Robison<sup>8</sup> has recently isolated from the products of fermentation by yeast juice a hexose-monophosphoric acid compound which gives on hydrolysis a hexose with a lower rotatory power than glucose. The present evidence points to the possibility that a special sugar may be formed in muscle which may readily break down into lactic acid.

#### *The Problem of a Reactive Sugar.*

With the idea that diabetes might be due to decreased formation of a reactive sugar we began in 1921 an investigation into the nature of the normal blood sugar by a comparison of its copper reducing and polarimetric values. For a determination of the latter the blood filtrate must be clear and concentrated to a small bulk owing to the small sugar content of normal blood. It was soon apparent that precipitation of the proteins by the usual methods was insufficient by itself, for on concentration the fluid invariably became turbid, showing the presence of unprecipitated protein. The proteins were precipitated according to the method of Folin and Wu; the filtrate was evaporated to dryness by distillation *in vacuo* at 40° C. The sugar was then extracted with 85 per cent. alcohol; the alcohol was distilled off under reduced pressure and the sugar taken up in a small quantity of water. While this method does not give a pure sugar solution, nitrogen determinations showed that only minimal amounts of such substances as urea, creatinine, etc., were present and the biuret and protein colour tests were negative.

By this method<sup>9</sup> we find that the blood sugar of man and animals has a lower rotatory power than would be given by  $\alpha, \beta$  glucose in equilibrium, the copper reducing value being reckoned as glucose. The polarimeter readings gradually approach the copper value and usually reach it in three days. While the time which elapses between the drawing of the blood and the determination of the rotatory power of the sugar being made is at least three hours, the sugar is in weak acid solution during the whole of this time, and alteration is likely to be reduced to a minimum.

Examination of the blood sugar of diabetics shows that the sugar has a higher polarimetric value than that of  $\alpha, \beta$  glucose. Control experiments, however, showed that solutions of  $\alpha, \beta$  glucose treated in the same manner as the blood filtrates gave slightly higher polarimeter values than those deduced from the copper reducing power. A possible reason for this was advanced, and it was suggested that in diabetes the blood sugar is mainly  $\alpha, \beta$  glucose. In certain cases of diabetes the polarimetric value was so much higher than that which would be given by  $\alpha, \beta$  glucose that we suggested that disaccharides or other substances with a higher polarimeter to copper reducing ratio than glucose might be present. We have obtained further evidence in the support of this view which will be discussed later.

As we have previously stated,<sup>9</sup> the nature of the normal blood sugar must be left undecided, though we hope in the future to obtain more direct evidence of its chemical nature. The facts now available suggest that it is of a reactive nature. The rotatory power is initially low, but tends to increase. Decolorization of  $\text{KMnO}_4$  is at first rapid, and then becomes slower as the rotation increases. The fact that the blood sugar in such a solution as we have obtained decolorizes  $\text{KMnO}_4$  more quickly than a solution of glucose of similar

concentration is of no significance, since many substances especially phosphates, accelerate the oxidation of glucose. It is only when the rate changes from day to day that it is permissible to suggest that a reactive sugar is present. Hewitt and Pryde<sup>10</sup> have shown that a solution of  $\alpha, \beta$  glucose in equilibrium introduced into the intestine of anaesthetized rabbits undergoes a rapid downward mutarotation. On withdrawal from the intestine the rotation increases and rapidly reaches the copper reducing value. Simple filtration was employed to obtain a clear solution. Fluids in contact with living tissues are apt to become contaminated with protein and other substances, especially if the tissues are injured. The differences, however, in the rotations observed are very striking. It was stated that  $\text{KMnO}_4$  was decolorized more rapidly by the sugar solution on withdrawal from the intestine than by Ringer-Tyrode solution or washings from the intestine. This does not dispose of the possibility that there may have been in the sugar solution some substance derived from the intestine which catalytically accelerated oxidation of the sugar by  $\text{KMnO}_4$ . That the phenomenon was not observed with sugar solution withdrawn from the peritoneal cavity does not invalidate this criticism. Indications were obtained that stereochemical changes took place in sugar solutions held in the mouth for a few minutes; the changes were slight, and difficulty in filtering the solution was caused by the saliva. The authors suggest that  $\alpha, \beta$  glucose is converted into  $\gamma$  glucose preparatory to absorption by the intestine. The reaction of the fluid was stated to be slightly alkaline, and the sugar reached equilibrium about twenty minutes after withdrawal. We have found that the blood sugar does not reach equilibrium for two or three days in acid solution. The influence of the reaction of the fluid is being studied, but it must be remembered that if the precipitation is carefully carried out, all but a trace of the tungstic acid combines with the proteins.

Whatever the precise nature of the normal blood sugar may be, the hypothesis of a reactive sugar being formed in the body is gaining ground. In a recent paper Laquer<sup>11</sup> gives the results of an investigation into the problem of lactic acid formation in muscle. He finds that lactic acid arises from glycogen under conditions in which the muscle can form no lactic acid from glucose. He concludes, "Glucose is burnt by muscle not directly, but after conversion into a reactive form. This reactive sugar is produced directly by the breakdown of glycogen."

#### *The Action of Tissue Extracts.*

In an attempt to determine whether tissue extracts could effect a change in the rotatory powers of glucose or fructose *in vitro*, we first examined the blood itself. Hewitt and de Souza<sup>12</sup> and Cooper and Walker,<sup>13</sup> using different methods, had previously stated that an enzyme of this nature is not present in blood. We could find no alteration in the rotatory power of  $\alpha, \beta$  glucose when it had been incubated with defibrinated blood and extracted by the usual method. More recently we have repeated these experiments with the blood of rabbits which have been killed after large doses of insulin, sufficient to cause convulsions. In every case the polarimeter reading was slightly above that obtained from the copper value.

No change took place when extracts of intestinal mucous membrane were used, either with or without the addition of insulin. More successful results were obtained when an extract of liver was employed.<sup>14</sup> When a solution of glucose or fructose was incubated at 37° C. in a jacketed polarimeter tube (2 Dm.) in the presence of liver extract and insulin, the rotation was changed in a downward and upward direction respectively. The presence of insulin was necessary; but insulin or liver extract by themselves were not capable of effecting any change. The influence of inorganic salts on the system was tested; phosphates appeared to have an accelerating effect. The very small quantity of liver extract used precludes the possibility of sufficient glycogen being present to cause error in the determinations. The copper reducing power of the sugar at the end of the reaction was unaltered. The fact that the liver factor is destroyed by boiling, while insulin is thermostable in acid solution, suggests that the function of the latter is to act as a co-enzyme or activator of some enzyme in the liver.

#### *An Effect of Insulin on Diabetes.*

On the supposition that diabetes might be due to diminished formation of a reactive sugar, it seemed interesting to test whether the nature of the blood sugar of diabetics might be

altered after injections of insulin. In conjunction with Dr. Devcreux Forrest,<sup>15</sup> we have investigated this possibility. Six cases were examined—severe and moderately severe. A sample of blood was drawn before treatment and the ratio polarimetric to copper reducing value of the blood sugar was determined. In each case the polarimetric reading was considerably above the copper value. An injection of insulin was then given each day for two or three days, and a second sample of blood drawn. In one case no change was observed; in the others the ratio polarimetric to copper reducing value had been lowered, showing that the blood sugar was more like that of normal persons. We have observed a further very marked difference between the blood sugar of diabetic and normal persons. We find<sup>16</sup> that when the blood sugar of diabetics is subjected to short hydrolysis by weak acid a marked increase takes place in the polarimetric value. The copper reducing power remains almost unaltered. On longer hydrolysis by stronger acid the polarimeter and copper values agree for  $\alpha$ ,  $\beta$  glucose in equilibrium. This phenomenon does not occur with the blood sugar of normal persons. We have not determined what is the sugar complex in diabetic blood which is responsible for this increase of polarimeter reading on hydrolysis. The facts would suggest that a polysaccharide is present which is readily broken down into strongly dextro-rotatory components. In preparing osazones from diabetic blood, we have in certain cases observed crystals other than those of glucosazone. On examining the blood sugar of diabetics after injections of insulin, we find in the case of the patients who have benefited from the insulin, that on hydrolysis the polarimeter reading does not increase above the copper value. In cases which have not had their ratio polarimeter to copper value altered by the insulin, we find that the polarimeter reading does increase, showing that this abnormal sugar is still present.

Though much more work is necessary to provide a satisfactory explanation, these facts are of significance in emphasizing the difference between the normal blood sugar and that of diabetics, and in showing that in most cases the blood sugar of diabetics is more normal after injections of insulin.

#### Action of Adrenaline.

It is well known that injections of adrenaline into animals raise the blood sugar. We have made some experiments to determine the ratio polarimeter to copper reducing value of the blood sugar after the concentration has been raised by injection of adrenaline. Under these conditions the nature of the blood sugar is considerably altered. The initial polarimeter reading is usually higher than the copper value, and it increases on short hydrolysis. The mixture of sugars would appear, therefore, to be similar to that in diabetic blood before treatment with insulin. On preparing phenyl-osazones, crystalline forms other than those of glucosazone have been observed. The amount of adrenaline injected into each animal varied from 0.5 to 1 c.cm. of a 1 in 1,000 solution. While the concentration of adrenaline in the blood must be momentarily far greater than any likely to occur normally, even in pathological conditions, the fact that it will cause a derangement of sugar production in such a way as to simulate the blood sugar of diabetics may not be without significance.

#### Action of Yeast Extracts.

We have made some experiments to determine how far an extract of yeast will lower the blood sugar of normal animals and diminish the symptoms of diabetes in man. The results tend to show that a substance similar to insulin may be obtained from yeast.

The action of the yeast extract on the blood sugar of the fasting rabbit may be seen from the following examples:

Rabbit 1 (weight 2 kg.).			Rabbit 2 (weight 2.5 kg.).		
Time.	Blood sugar.		Time.	Blood sugar.	
10.20	...	0.15 %	11.45	...	0.11 %
10.45, yeast 0.63 mg. per gm. body weight injected	...	0.11 %	12.3, yeast 0.65 mg. per gm. body weight injected	...	0.08 %
12.0	...	0.05 %	2.45	...	0.05 %
2.15	...	0.05 %	5.0	...	0.05 %
3.45	...	0.05 %	6.0	...	0.05 %
5.45	...	0.07 %	7.0	...	0.05 %

The animal went into convulsions; 40 c.cm. of a 10 per cent. solution of glucose were injected subcutaneously. Complete recovery resulted.

Through the kindness of the consulting physicians and staff of Addenbrooke's Hospital, we have been able to test the effect of the yeast extract on diabetic cases. Two cases had

been rendered sugar-free by diet (Graham) before treatment with yeast extract. The others were given injections soon after admission to hospital. An unusually large quantity of protein is allowed by the Graham diet during the early days of treatment; but when the twenty-four hours' urine contained sugar, it was found that the urine passed up to seven hours after the injection was sugar-free, even in severe cases. Of the seven cases examined, five showed marked improvement. Only one injection was given each day, as we had previously found with pancreatic insulin that this was sufficient to cause definite improvement.

In three cases a sample of blood was drawn before treatment with yeast extract and the ratio polarimeter to copper value determined. All had a high ratio; in one case it was unusually high. One of the cases was sugar-free by diet; this, we had previously found, alters only the amount and not the nature of the blood sugar. After several days of treatment a second sample was drawn and the ratio redetermined. In all three cases the ratio had improved; in two the polarimeter reading was definitely below the copper value. In each case hydrolysis showed that no trace of polysaccharide was present. The results appear to be identical with those which we have previously obtained after injection of pancreatic insulin into diabetics. Two cases of long-standing disease showed no improvement from injection of yeast extract or pancreatic insulin. A possible reason for this is advanced in the discussion.

Table of Clinical Experiments.

	Polarimetric Readings on Successive Days.	Copper Value.
L. B. W., normal (100 c.cm. blood) ...	0.07, 0.11, 0.13, 0.14	0.11
L. B. W., after 100 grm. glucose 55 c.cm. blood)	0.4, 0.05, 0.03, 0.09	0.03
L. B. W., after 150 grm. fructose (100 c.cm. blood)	0.05, 0.03, 0.10, 0.13	0.16
Diabetic before insulin (55 c.cm. blood)	0.15, 0.12, 0.11, 0.10	0.03
Diabetic after insulin (85 c.cm. blood)	0.05, 0.03, 0.03	0.05
J. S., before yeast extract (50 c.cm. blood)	0.19, 0.18	0.13
J. S., after yeast (71 c.cm. blood) ...	0.13, 0.14	0.15
S., before yeast (50 c.cm. blood) ...	0.11, 0.09, 0.03	0.05
S., after yeast (65 c.cm. blood) ...	0.09, 0.11, 0.12	0.13
J. M., before yeast (30 c.cm. blood) ...	0.21, 0.15	0.01
J. M., after yeast (40 c.cm. blood) ...	0.17, 0.10, 0.10	0.10

The following are the blood sugar determinations (quantitative) on C. R., aged 11 years. This case received yeast extract only. On one day no injection was given. The blood sugar remained high on this day.

First Day.		Second Day.		Third Day.	
12.45	0.14%	12.30	0.13%	11.0	0.13%
1.0, 50 mg. yeast		12.45, 50 mg. yeast		12.0, 90 mg. yeast	
3.30	0.1%	3.30	0.09%	3.15	0.12%
7.0	0.05%	6.15	0.14%	5.30	0.16%
9.0	0.11%				
Fourth Day.		Fifth Day.		Sixth Day.	
12.0	0.22%	12.0	0.22%	12.0	0.11%
No injection		12.30, 100 mg. yeast		12.30, 100 mg. yeast	
3.0	0.20%	3.0	0.13%	3.15	0.08%
6.0	0.15%	6.0	0.10%	5.30, 10 gm. cane sugar by mouth	
				6.15	0.12%

During the first two days of treatment with yeast extract he was given 1 oz. bread a day above diet. During the remaining four days this was increased to 1½ oz. On the last day cane sugar was given as a precautionary measure. Since this he has been on an adult diet (full Graham), with addition of bread and, as a rule, also potatoes. He has remained sugar-free.

R. This case reacted neither to yeast extract nor to pancreatic insulin. The ratio polarimeter to copper reduction was unchanged. Before treatment: Polarimeter, 0.10; copper value, 0.07. After treatment: Polarimeter, 0.10; copper value, 0.07.

First Day.		Second Day.		Third Day.	
10.30	0.10%	11.0	0.14%	11.15	0.12%
(30 c.cm. blood drawn.)		11.70, 140 mg. yeast.		11.30, 140 mg. yeast.	
11.0, 140 mg. yeast.		3.45	0.12%	1.45	0.11%
3.0	0.10%	6.15	0.12%	6.0	0.12%
Fourth Day.		Fifth Day.

#### GENERAL DISCUSSION OF RESULTS.

Two theories of diabetes have been suggested. The first attributes the disease to overproduction of sugar, regarding the pancreas solely as an inhibitory mechanism. The second theory holds that the disease is due to progressive inability of the tissues to utilize sugar; and that in some way the internal secretion of the pancreas enables the tissue cells to grip the sugar and oxidize it. The deficient utilization of sugar in diabetes, as shown by the respiratory quotient and wasting of the tissues, is ascribed by supporters of the first theory to the toxic effect on the cells of the high concentration of sugar, the very excess of sugar offered impairing the power of the cells to oxidize it.

Evidence pointing to a reactive sugar being formed in the body lends powerful support to the second theory. The sugar which reaches the cells contains a lessened amount of a reactive type; the high blood sugar may be explained by regarding the sugar as a mixture of normal and abnormal types. The normal blood sugar is removed by the cells and oxidized, the abnormal cannot be burnt, and is excreted. As the disease progresses the proportion of normal blood sugar becomes smaller, and the continued call of the tissues for an oxidizable sugar causes the blood sugar concentration and the excretion in the urine to become greater.

In a theory of diabetes put forward by Ringer<sup>17</sup> the author suggests that failure to utilize fat and carbohydrate is due to failure to accomplish a glucosidic union between the two molecules, and that the excretion of acetone bodies and sugar may be explained by the fact that they have not been linked together prior to metabolism by the cell. This hypothesis fits in well with the view of a reactive sugar.

The difference in the nature of the blood sugar of normal and diabetic persons is against the overproduction theory; on this theory the diabetic blood sugar should differ from the normal only in quantity. Further, injection of insulin into diabetics alters the nature of the blood sugar, with certain exceptions shortly to be discussed.

That at least two factors are concerned in the change is probable from the experiments on the action of insulin and liver extract on glucose and fructose *in vitro*. The optical activity of the sugar solutions was altered with no change in the copper reducing value. This suggests that the differences observed could not have been due to oxidation of the sugar or removal by some other means. Further, after the maximum change was observed, the rotation tended to revert to its original value; probably some component of the system was being inactivated and destroyed. We hope to make a further investigation on this point with a view to determining the conditions of activity of the enzyme. These experiments afford no indication as to the purpose of the sugar which was formed. Is it a preliminary to the formation of glycogen, or, granting that  $\alpha, \beta$  glucose is formed from glycogen in the body, is it in process of converting this sugar into a reactive form for utilization?

The evidence at present available would suggest that glycogen may yield different sugars under different conditions. While the normal blood sugar has a low rotatory power, the blood sugar of animals after injection of adrenaline approaches that of the diabetic in its nature. In examining the blood sugar of man, we found in one subject, who had no diabetic history, that the sugar had a rotatory power corresponding to the copper value. Possibly nervous influences, the result of the operation of drawing the blood, had affected the normal breakdown of glycogen. Macleod and his co-workers have shown, by a study of the respiratory quotient, that injection of insulin causes an increased utilization of sugar. They have also shown that insulin causes considerable formation of glycogen in the liver of depancreatized dogs. It is possible that the normal blood sugar is a mixture of  $\alpha, \beta$

glucose and a reactive sugar, and that insulin shifts the equilibrium in the direction of increased formation of the reactive sugar, which is then stored or utilized, the latter depending on the need of the tissues for sugar.

When a large dose of insulin is given to an animal the blood sugar falls to a point incompatible with life—the nervous system is affected and convulsions ensue. Banting and Best have shown that these symptoms can be relieved by injection of glucose. We have recently found that rabbits which are in convulsions as a result of injection of insulin (three times minimum lethal dose) may be restored to a normal condition in a short time by injection of adrenaline. A probable explanation is that glycogen is broken down by the liver and sent into the blood.

	Time.	Blood Sugar.
Rabbit, weight 1,800 grams	9.45	0.12 per cent.
Insulin (pancreatic) 0.03 mg.	10.0	
per gram body weight	11.40	0.07 per cent.
Convulsions occurred	12.45	0.05 "
1 c.cm. 1 in 1,000 adrenaline given intravenously	12.50	
Animal normal	1.30	0.09 per cent.
	3.0	0.16 "

In the case of an animal which did not recover following administration of adrenaline, the liver was examined; it was found that a new growth had greatly diminished the amount of normal liver tissue. It is possible that in certain cases of diabetes impairment of some organ other than the pancreas may have occurred. Certain cases of diabetes we have found not to react readily to insulin from the pancreas or to an extract of yeast. Two showed no improvement whatever. Both had had the disease for many years. It is suggested that the liver may have been affected. On the view that the liver contains an enzyme which is concerned with the production of a reactive sugar, gradual inactivation of the enzyme may have taken place to a considerable degree; possibly consequent on deficient formation of the pancreatic hormone.

A point of difficulty arises when it is remembered that the muscles of the diabetic contain glycogen, the heart muscle especially being often abnormally loaded with it. The liver, on the other hand, is usually almost free of glycogen. It is possible that carbohydrate metabolism in muscle may be of a special kind, or, as the powers of the body to metabolize sugar become diminished, that the essential organs are kept supplied with what little reactive sugar is available, to the exclusion of the call of the less essential tissues. On the other hand, the abnormal glycogen content of the heart muscle may point to deficient power of utilization of this sugar. Possibly there may be more than one internal secretion of the pancreas.

Evidence is accumulating to show the delicate balance which exists between the various internal secretions of the body. On these lines may come the explanation of the gradual deficiency of the pancreatic hormone in diabetes. Owing to the very delicacy of the adjustment between the glands, caution must be observed in interpreting the results of injection of large doses of the secretion of any one of them. It is inadvisable, therefore, at the present stage, to theorize too precisely on the manner in which the pancreas influences the carbohydrate metabolism of the body.

#### Summary.

1. The normal blood sugar of man and animals has a lower rotatory power than  $\alpha, \beta$  glucose. It is probably of a reactive nature.
2. The blood sugar of diabetics is mainly  $\alpha, \beta$  glucose.
3. A more complex sugar is also present in diabetic blood.
4. In the majority of diabetic cases injection of insulin causes a change in the nature of the blood sugar. The complex sugar disappears and the ratio polarimeter to copper reducing value is altered.
5. Insulin and liver extract together alter the rotatory powers of  $\alpha, \beta$  glucose or *D*-fructose *in vitro*.
6. Injection of adrenaline into normal rabbits causes the blood sugar to be altered. It appears to become like that of diabetics.
7. An extract of yeast has an effect similar to that produced by insulin, when tested on animals and on diabetic persons.

8. Insulin convulsions in rabbits may be relieved, and the animals restored to normal, by injection of adrenaline.

## THE ADMINISTRATION OF INSULIN BY INUNCTION.

BY

S. V. TELFER, M.B., Ch.B., B.Sc.

(Institute of Physiology, University of Glasgow.)

DURING the course of recent experimental work in conjunction with Professor D. Noël Paton on the isolation and subsequent testing of insulin the possible methods of administering this preparation formed one of the subjects of consideration. The method of subcutaneous injection of sterilized aqueous solutions of known strength was employed in the determinations of "potency" of the insulin which was isolated from time to time in the laboratory. Hypodermic medication has also been employed habitually in the clinical use of this material. It is obvious, however, that if the drug is to be employed for long periods this method of administration might, in many cases, prove to be a serious drawback.

In considering the possible methods of administration, it occurred to me that the skin surface might be utilized for the absorption of the drug by inunction. The following experiments on rabbits were accordingly carried out, to ascertain primarily if the inunction of a paste in which insulin was incorporated would produce the effects obtained by direct injection of an insulin solution.

Simple ointments of varying strength were made by mixing weighed quantities of crude insulin, isolated from ox pancreas in the laboratory (by the method communicated by Dr. Dale of the National Institute for Medical Research) with small quantities of lanoline and with lard. The abdomen of each rabbit, which had been starved for seventeen hours, was shaved, care being taken to avoid injury to the skin surface, and the insulin paste gently rubbed in over the bare area.

TABLE I.—Inunction of Insulin in Rabbits.

	Weight of Crude Insulin used.	Blood Sugar.		Remarks.
		Time Intervals.	Glucose per cent.	
Experiment 1. Mar. 30, 1923.	0.3 gm. in 1 gms. hydrous lanoline	10.50 p.m. 12 noon 2.30 p.m. 5.0 p.m. 10.0 p.m.	0.152 0.059 0.045 0.056 0.084	Slight twitching of head at 2 p.m., but no convulsive movements.
Experiment 2. Apr. 4, 1923.	0.07 gm. in 2 gms. hydrous lanoline	11.5 a.m. 12.5 p.m. 2.50 p.m. 8.10 p.m.	0.103 0.091 0.031 0.11	No signs evident.
Experiment 3. Apr. 10, 1923.	0.3 gm. in 3 gms. "adepts preparatus"	11.35 a.m. 12.35 p.m. 2.53 p.m. 4.30 p.m. 8.20 p.m.	0.103 0.035 0.052 0.075 0.093	No convulsions.
Experiment 4. Apr. 10, 1923.	1 gm. in 5 gms. "adepts preparatus"	11.45 a.m. 12.45 p.m. 3.8 p.m. 4.10 p.m.	0.112 0.054 0.034 0.02	Animal somewhat collapsed at 3.30 p.m. Convulsive seizures at 4.10 p.m. Recovery. 1 gm. glucose injected. Animal ate green food, but at 6.40 p.m. convulsions occurred again. Recovery after injection of 2 gms. glucose.

TABLE II.—Subcutaneous Injection of Insulin in Rabbits.

	Weight of Crude Insulin injected.	Blood Sugar.		Remarks.
		Time Intervals.	Glucose per cent.	
Experiment 5. Mar. 1, 1923.	0.16 gm. (at 11.15 a.m.)	11.11 a.m. 11.45 a.m. 12.16 p.m. 12.46 p.m. 1.17 p.m. 2.30 p.m. 11.10 a.m.	0.107 0.093 0.077 0.051 0.038 0.013 0.094	Convulsions at 2.30 p.m. 1 gm. glucose injected. Convulsions at 3.1 p.m. 2 gms. glucose i.j. ctd.; recovery.
Experiment 6. Mar. 6, 1923.	0.075 gm. (at 11.25 a.m.)	11.20 a.m. 12 noon 1.0 p.m. 2.30 p.m.	0.162 0.075 0.054 0.051	No convulsions.
Experiment 7. Mar. 12, 1923.	0.067 gm. (at 11.15 a.m.)	11.12 a.m. 11.56 a.m. 12.50 p.m. 1.15 p.m.	0.177 0.073 0.053 0.041	Convulsions at 1.10 p.m. 1 gm. glucose injected; recovery.
Experiment 8. Mar. 16, 1923.	0.027 gm. (at 3.15 p.m.)	3.10 p.m. 4.20 p.m. 5.10 p.m.	0.133 0.018 0.051	No convulsions.

This procedure generally lasted about five minutes. The treated area was then covered with a piece of jaconet, held in position by a bandage. Samples of blood from the marginal vein of the ear were taken for estimations of blood sugar, immediately before and at intervals after the inunction of the paste. The results obtained are collected in Table I. For purposes of comparison the effects produced on the blood sugar of rabbits by subcutaneous injection of various quantities of crude insulin are given in Table II.

In the first experiment (No. 1, Table I) a relatively large amount of insulin was employed, to ascertain if any effects could be produced by inunction. As noted, there was a reduction of blood sugar to 0.045 per cent., though no convulsions were induced during this period. The hypoglycaemia was still pronounced twelve hours after administration. A much smaller amount of material was employed in Experiment 2. The fall in blood sugar was just observable. The hypodermic injection of the same quantity of insulin (Experiment 7, Table II) induced convulsions in another animal within two hours. In Experiment 3 the crude insulin was incorporated in lard. The inunction of the paste induced a very considerable fall in blood sugar within an hour, the period of hypoglycaemia lasting about ten hours. A large excess of insulin was employed in Experiment 4. Soon after inunction the animal became very lethargic, and within an hour its appearance suggested collapse, though there were no convulsions till 4.10 p.m., when glucose was injected subcutaneously. The animal remained in a collapsed condition for some time, but later seemed to be normal, and ate some green food. At 6.40 p.m. it was again in a strongly convulsed state; 2 grams of glucose were injected subcutaneously. At 10 p.m. it appeared to be recovering, but refused green food. On the following morning it had completely recovered and was actively running about. The reduction in the blood sugar was very pronounced in this experiment, and a considerable amount of insulin must have been rapidly absorbed through the skin.

An examination of the results obtained on the subcutaneous injection of crude insulin (Table II) shows that by this method of administration the maximum effects could be produced with very much smaller doses. In Experiment 8 the reduction of the blood sugar to 0.038 per cent. resulted about one hour after the injection of 0.027 gram, while in Experiment 7 convulsions occurred with the fall in blood sugar to 0.041 per cent. two hours after the injection of 0.067 gram.

In reviewing these results the chief conclusion appears to be that insulin can be introduced into the blood stream by means of inunction. This method of administration necessitates the use of much larger quantities of the drug than those required to produce comparable effects by subcutaneous injection. It is worthy of note, however, that in estimating the effects produced account must be taken chiefly of the duration of the hypoglycaemia. A sudden reduction, followed by an abrupt rise in the blood sugar, such as is indicated in Experiment 8, Table II, where a relatively small amount of the drug was injected, indicates a transient effect. The ideal method of utilization would appear to be indicated by a

prolonged period of hypoglycaemia maintained by slow absorption.

The results also suggest that advantage might be taken of this method to utilize crude insulin extracts. At the present time the cost of isolating the drug in a pure and active state for the purposes of hypodermic medication is such as to restrict seriously its application on a large scale. It is possible that more liberal use of cruder materials might with advantage be made by means of injection.

I have to thank Mr. Orr for performing the analyses of the blood.

The work was done under the Medical Research Council.

## A Clinical Lecture

ON

## SUBCUTANEOUS RUPTURE OF THE INTESTINE.

GIVEN AT GUY'S HOSPITAL ON MARCH 7TH, 1923,

BY

R. P. ROWLANDS, M.S., F.R.C.S.,

SURGEON TO GUY'S HOSPITAL.

CONTUSIONS, unlike bullet and other penetrating wounds, do not often cause multiple injuries of the bowel, but the individual lacerations of the intestine and mesentery are generally more severe. For instance, the small intestine is sometimes completely divided. Therefore it is clear that the hope of recovery without operation is more remote, but the operation itself is likely to be less tedious and troublesome.

### CAUSE.

The bowel is most frequently ruptured by a wheel passing over the abdomen, by a squeeze or a crush, a blow or a kick. It may be crushed against the spine or torn from its mesenteric attachments, especially at the junction of movable and fixed parts, such as the duodeno-jejunal junction. Sometimes the reduction of a strangulated hernia has led to rupture of the bowel; a man was admitted to Guy's Hospital recently who had ruptured his own intestine in this way. In the large majority of cases, as pointed out by Massie, the contusion is below the umbilicus; there may be, however, no sign of injury on the surface of the abdomen at first, but a bruise may appear some days later.

### SITE OF RUPTURE.

In an examination of 381 cases, published and unpublished, the site of rupture was as follows:

Duodenum	...	...	...	...	23 cases.
Jejunum	...	...	...	...	157 "
Ileum	...	...	...	...	158 "
Colon	...	...	...	...	43 "

In one-tenth of the cases there was more than one rupture; sometimes the large as well as the small intestine was torn.

### NATURE OF DAMAGE.

As a rule the laceration runs for less than an inch across the axis of the bowel, but occasionally the latter is completely divided or severely bruised. The mucous membrane always pouts; the bowel dilates above and below the rupture, and rapidly becomes inflamed and oedematous. In nearly one-tenth of the cases there are complications, such as rupture of the mesentery or of one or more of the other abdominal viscera. In one-quarter of the cases there is fracture of the spine or pelvis, and sometimes severe injuries to other parts, such as the chest and head. The frequency and severity of these complications contribute very largely to the mortality.

### SYMPTOMS AND SIGNS.

1. *Pain* is the most striking symptom: As a rule it comes on early and is very severe, being described by patients as "agonizing."

2. *Tenderness*.—This is at first local, near the site of the injury, but later it becomes general, as a result of peritonitis.

3. *Shock*.—This is nearly always severe. It occurs, and may even be fatal, very soon after the accident. In some cases it passes comparatively quickly.

4. *Vomiting* is almost always present, often constant and most persistent.

5. *Pulse and Temperature*.—The former is at first slow and weak from shock, then normal and deceptive; later increasingly rapid and weak as a result of peritonitis. Similarly the temperature is at first subnormal, then normal, and later raised.

6. *Rigidity*.—At first this may be local, but it soon becomes general. The abdomen may be flat at first, or even retracted, but later it becomes distended as a result of peritonitis, with effusion and tympanites.

7. *Dullness*.—There is usually shifting dullness in the flanks as a result of effusion. The liver dullness is often greatly diminished from free gas in the peritoneum.

8. *Transmission of Heart and Breath Sounds*.—The heart and breath sounds may be transmitted, through the gas and fluid, over the abdomen, far beyond the natural limits.

9. *Signs of Internal Haemorrhage*.—In many cases the patient is pale and restless as the result of haemorrhage, and examination of the blood confirms the evidence of this grave complication. The face is usually anxious, pale, cold and sweating, and is, in fact, a typical "abdominal facies."

Emphysema of the abdominal wall or of the loin generally implies rupture of the bowel in its extraperitoneal part. When it affects the right loin the ascending colon or duodenum is ruptured; on the left side, the descending colon. Later on, in such cases, a faecal abscess may form in the loin.

As a rule the minds of these patients are unusually active, and they often have a premonition of impending death.

### DIAGNOSIS.

The diagnosis depends a great deal upon an accurate history of a severe abdominal injury. Anyone who has sustained such an injury should be kept under direct observation for a few days, for although there may be no bad signs at first these may rapidly develop. It is of the gravest importance to admit such a case into hospital at once.

Severe pain, tenderness, rigidity, and persistent vomiting following an abdominal injury should make us open the abdomen without delay, although the pulse and temperature and general condition of the patient may be good. It is by operating in the early stages that the appalling mortality of these catastrophes can be reduced.

It is often difficult to distinguish this condition from rupture of the spleen, liver, or mesentery, in which signs of internal haemorrhage and shock are the most prominent. Presence of free gas in the peritoneum, as shown by a tympanitic note, diminution of the liver dullness, and rapid onset of peritonitis, are strong indications in favour of rupture of the bowel; but accurate diagnosis is not so important as a realization of the presence of grave intra-abdominal injury and the urgent need of an operation to set it right.

### TREATMENT.

Death is almost inevitable without early operation, therefore it should be carried out at the earliest possible moment, for mortality increases with delay. The following figures, taken from 376 operation cases collected by Siegel, illustrate this point:

	Mortality.
Operation within 4 hours	15.2 per cent.
" from 5 to 8 hours	41.4 "
" from 9 to 12 hours	63.6 "
" later	70.0 "

The mortality of this series was 51.6 per cent., and is very misleading, because fatalities are so often forgotten and not published.

### Operation.

While preparing for the operation every endeavour must be made to combat shock by warmth, saline or subcutaneous infusions, or, in some cases, by transfusion of blood. Whenever possible spinal anaesthesia or gas and oxygen is chosen.

The abdomen is opened in the middle line, preferably by displacement of the right rectus outwards. The jejunum, being the most likely part to be affected, is at once examined and the small intestine traced downwards to the caecum. In many cases, however, the injured coil comes forwards into the wound directly the abdomen is opened, and gas and liquid escape. If no perforation is found in the jejunum or ileum the duodenum is most carefully examined; in many cases lacerations of the duodenum have been overlooked at the time of operation and have only been found *post mortem*. Lastly, the caecum and colon are examined.

Unless a loop of intestine has been very severely damaged it is not necessary to resect. It is far safer to pare the edges of the laceration and to close it with two continuous sutures of fine linen thread. Linen thread closes wounds in these damaged tissues more effectively and permanently than fine catgut and does no harm. While the surgeon is closing the perforation gauze rolls are passed into the pelvis and flanks to absorb the effusion in these areas. This is a quicker and better method than washing out, and the peritoneum is left dry and less damaged. In late cases a stab wound is made about two inches above the pubis and a tube is inserted to drain the pelvis, but in early cases the peritoneum is completely closed.

#### MORTALITY.

The mortality of this condition is appalling, and is chiefly due to delay and errors of diagnosis. James Berry and Giuseppe<sup>1</sup> have done good service by collecting and analysing 132 cases of rupture of the intestine from contusion, from the records of ten London hospitals, previous to 1908. Of Berry's collection, 84 patients were operated upon, with 67 deaths—a mortality of 80 per cent.; but in 15 the ruptures were not found at the operation; 7 of these were in the duodenum. The surgical registrars of twelve London hospitals collected 44 cases occurring between 1908 and 1912.<sup>2</sup> In 12 of these there was no operation. Of 32 operated upon, 23 died (72 per cent.). Taking these two series together, there were 176 cases, with 116 operations, and a mortality of 77 per cent. It is interesting to note that 60 (or over one-third) of the patients were not submitted to operation. This was chiefly due to their grave condition on admission, owing to delay or the presence of complications.

It is certain that the best results are obtained by quick decision, early operation, and accurate and rapid work at the operation, followed by careful after-treatment.

#### CASE I.

Mrs. T. H., aged 43, had been up to London, and was walking from the station to her home, at 4 p.m. on September 4th, 1922. She was carrying a heavy suit-case, which had hard protected corners, when she was run into from behind by a cyclist. She was thrown violently forwards and doubled up over the case, one of the corners of which injured her in the right hypochondrium, and the cyclist fell on top of her. She crawled to the side of the road in terrible agony and scarcely able to breathe or speak. A doctor was fetched who, however, did not think anything very serious had occurred, and he took her home (four miles) in a taxi. She almost fainted before entering the taxi, but took some sal volatile which made her feel better. She could not sit up or lean back, and especially could not bear to be touched on the abdomen or trunk. Arrived at home she crawled upstairs on her hands and feet, holding her body rigid but shaking all over. She was given a cup of tea, but vomited at once. Dr. G.-J. was called in late that night and found her with a rigid abdomen and very tender in the right flank. Pulse and temperature were normal. She was vomiting a little, but brought up no blood. A diagnosis was made of "bruised ribs and abdominal wall." As the pain was still very great he, at the urgent request of the husband, gave an injection of morphine (1/4 grain), but the following morning it was as bad as ever, and, as he was unhappy about the patient, Dr. G.-J. got me to see her at noon. Although the abdomen did not move well on respiration, I did not think there was sufficient cause for operation, but by 8 p.m. she was much worse. The pulse was 124, and temperature 102°; the abdomen was getting more distended and she was very flushed; the liver dullness had almost disappeared, and the pain was so intense that the patient welcomed the idea of an anaesthetic as she longed for unconsciousness. A diagnosis was made of "ruptured viscus, bowel, or gall bladder," and an operation advised and carried out at once. From the moment of the accident the patient had an acute sense of impending death and the brain was more than usually active throughout, in spite of the pain suffered.

**Operation.**—On opening the abdomen through the right rectus gas at once escaped, also foul, bile-stained pus, of which there was a large amount in Morison's pouch. There was a large collection of thinner sero-pus in the pelvis. This was mopped away, and two rents, large enough to admit the tip of the finger, were found in front at the junction of the first and second parts of the duodenum. There was a narrow bridge between the two rents which I divided. There was no induration of the duodenum nor any evidences of chronic ulceration. Moreover, the mucous membrane pointed, which it never does for a perforated ulcer, because it is adherent at the edge of the ulcer. The large opening was then closed with fine linen thread in two layers, the line of suture being transverse to the duodenum, so that the lumen would not be narrowed. The omentum, above and below the duodenum, was then brought over the suture line. A tube was left in a stab wound just above the pubis and another in the abdominal wall just above the wound. The patient vomited a good deal during the next forty-eight hours, bringing up black vomit; the temperature kept up for a week, and there was considerable suppuration in the abdominal wound and some cystitis. She slowly regained strength, however, and made a complete recovery.

#### CASE II.

A man, aged about 21, in the Officers' Training Corps, at 9 p.m. on December 29th, 1915, was struck in the abdomen by the handle of a handcart. It hurt him very much, but he did not fall and later went home to Woolwich. He did not sleep at all that night, having dreadful pain in the abdomen and vomiting frequently. He was seen by Dr. Baird, who sent him up to Guy's Hospital the following day. On admission he looked ill and anxious; temperature 100°, pulse 110.

**Operation** (December 30th, 5 p.m.).—The abdomen was flat, completely fixed, and exquisitely tender, but it was quite resonant over the liver and in the flanks. He was unable to pass urine, but the bladder was not fully distended, only 6 ounces of clear, high-coloured urine being removed with a catheter. A diagnosis of ruptured small intestine was made, for the signs of peritonitis were much too severe for anything else. Pallor was not very marked. A very long incision was made to the right of the middle line. Pus and gas at once escaped, followed by brownish, very offensive fluid. There was lymph on the coils of small intestine, which I withdrew in order to find the perforation without delay. Ultimately I found a very large laceration, 2½ in. long, across the dilated, oedematous jejunum, high up. The perforation was lying far back in the left flank, near the spleen. I withdrew it, after separating some adhesions, pared the edges, and closed the opening with two continuous fine black threads. Meanwhile, gauze rolls had been draining away the fluid from the flanks and pelvis. There was general peritonitis. A tube containing a wick of gauze was inserted in the pelvis, through a stab wound above the pubis. The main wound was closed completely in layers. The patient was infused throughout the operation. He made a complete recovery.

### A CASE OF INTESTINAL STASIS.

BY

G. DUNDAS MAITLAND, M.B., B.S., F.R.C.S.,

MEDICAL OFFICER TO OUT-PATIENTS, ROYAL SURREY COUNTY HOSPITAL.

THE case I am about to describe seems to warrant publication more by the multiplicity than by the rarity of the abnormal features it presented. The patient was referred to me by Dr. Cowardin of Guildford with the provisional diagnosis of "colon disease," which was, perhaps, the happiest term that could have been chosen, for the whole of the colon was in a pathological state.

Mrs. W., aged 46, had always been an active woman, and gave a life history free from any abdominal trouble, inflammatory or otherwise, until about five years ago, when she began to be troubled with chronic constipation and colicky pain, which gradually became more persistent; for two years she had had constantly to resort to the use of laxatives, but was often quite constipated for periods of four or five days, generally followed by a few days of diarrhoea. Pain of a colicky nature had for a year been almost constantly present on the left side; it was most severe for about two hours prior to the morning evacuation, which was becoming more difficult.

Considerable quantities of mucus had been passed with the stools for two years, and for some time the stools had taken the form of small, hard, rounded nodules; tenesmus had become a marked feature. She was never sick or visibly distended and melaena had never been noticed. A barium enema was administered and its passage through the colon examined with the fluoroscopic screen. There was no noticeable delay at any point, the opaque material passing round to the caecum in the normal five minutes without any massaging, but there was noticed a very severe kinking of the ascending colon at a point about on the level with the iliac crest; at this point the column of barium was thinned out and, for a time, broken. The splenic flexure appeared in good position, but the hepatic was unusually low. A week later the patient entered a nursing home and a barium meal was administered by the mouth. Four hours later the stomach had emptied and the opaque meal was all collected in the terminal ileum; at eight hours the caecum had begun to fill; at twelve hours the whole of the opaque substance had passed into the caecum and ascending colon.

Fluoroscopic examination showed that the caecum was unusually large and that the ileo-caecal junction was well below the level of the brim of the true pelvis. The ascending colon appeared very short, the hepatic flexure being about the level of the iliac crest.

At twenty-six hours the bulk of the barium was still in the caecum and ascending colon; only a few small pellets of barium were seen in the transverse and upper part of the descending colon down to the level of the kink noticed on giving the opaque enema; but as these all threw small separate shadows, no definite evidence of obstruction at this point could be demonstrated.

The marked general stasis and proptosis of the caecum and ascending colon decided us to advise operation. Through a large paramedian incision the whole colon was explored, working from below upwards. The rectum was normal. The pelvic colon was greatly elongated (about two feet) and lay loose in the cavity of the true pelvis, to the walls of which it was attached by a long loose mesentery which allowed of its being withdrawn freely from the pelvic hollow. The kink seen in the first radiographic examination was a typical "Lane's last kink," being caused by a dense

band stretching from the brim of the true pelvis into the mesentery of the colon; at its attached end it is perhaps best described as resembling the blade of a razor set in the mesentery, the thick back portion being towards the lateral abdominal wall. As it approached the lateral surface of the bowel it became spread out to form a thin sheet, the fibres of which passed actually into the peritoneal covering of the lateral aspect of the colon. It had not contracted sufficiently to tie the bowel at all tightly to the pelvic brim, and there was no external evidence of constriction of the lumen at this point. The descending colon was throughout provided with a loose abnormal mesentery, three to four inches in length at the iliac end, and about two inches as it approached the splenic flexure, which was normally fixed in good high position. The transverse colon appeared normal but sagged rather low in the centre; this probably was partly due to the low position of the hepatic flexure. The ascending colon was greatly dilated; it also appeared to have an abnormal mesentery, but this was not easy to demonstrate because the anterior and external surfaces were invested with an extensive Jackson's membrane spreading from the colon to the lateral abdominal wall. In places this membrane was of the thin diaphanous type usually described, but in others it presented patches and bands of firm glistening fibrous tissue which were strong enough to resist digital separation. The caecum was more grossly dilated; it was entirely within the hollow of the true pelvis, and a large, thickened, chronically diseased appendix lay on the fundus of the urinary bladder.

The caecum was readily withdrawn from its pelvic bed, there being no adhesions in that cavity. A band stretched from the anterior surface of the caecum to the front of the terminal ileum, about two inches from their junction, but this did not appear to be causing any kinking of the latter. Lane's ileal kink was not present, nor were there any gall stones. The stomach was normal in size and high in position; it showed no sign of ulcer or other disease.

As the interest of this case lies entirely in the extensive pathological features present, there can be no purpose served by describing the operative procedures carried out. They were conservative in character, though I cannot help feeling that this was a case in which nothing short of a complete colectomy could be expected to yield any great degree of permanent benefit. I may add that this is one of the very few cases of this type in which I have felt thoroughly convinced that such a drastic operation would have been (in the hands of one accustomed to performing it) completely justified.

The points of special interest in this case appear to me to be: (1) the unduly long and mobile pelvic colon; (2) the Lane's "last" kink; (3) the descending mesocolon; (4) the proptosed dilated caecum and ascending colon with mesocolon; (5) the Jackson's membrane, and its remarkable density; (6) the inability of the caecum and ascending colon to propel their contents as shown by x rays.

In the performance of the operation I was greatly assisted by Dr. C. P. Lankester (Surgeon to the Royal Surrey County Hospital), who had carried out the radiographic examinations which had portrayed the actual conditions found at operation with such accuracy.

## TREATMENT OF STRANGULATED OBTURATOR HERNIA.

BY

A. RENDLE SHORT, M.D., B.S., F.R.C.S.,

SURGEON TO THE BRISTOL ROYAL INFIRMARY.

STRANGULATED obturator hernia must be regarded as a rare condition. The case here recorded is the only one that has occurred in the practice of the Bristol Royal Infirmary, which is the largest hospital in Bristol, in about twenty-five years. It might, however, fall to the lot of any surgeon, in town or country, to deal with the condition. Most of the described cases have occurred in old women. The diagnosis is usually acute intestinal obstruction, as it was in my case at the first time of strangulation, but occasionally there may be pain down the distribution of the obturator nerve, or a deep swelling beneath the origin of the adductor muscles, to suggest the correct diagnosis.

The best account of the anatomy and operative treatment of the condition with which I am acquainted is in Lejars's *Urgent Surgery*, vol. ii. Three types of obturator hernia are described.

1. The bowel may traverse the whole length of the canal, emerging from the anterior aspect, and spreading out in front of the obturator externus and under cover of the pectineus.

2. It may push through the obturator externus muscle, not through the canal with the artery and nerve, and so be encircled by muscle fasciculi.

3. It may burrow into the layers of the obturator foramen beneath the obturator externus muscle, so that that muscle covers it, as well as the pectineus, when an attempt is made to dissect down to it from the groin.

The artery and nerve bear no constant relation to the sac. Usually they are behind the neck and a little to its outer side, but cases have occurred in which the artery has formed a circle around the neck.

It is generally advised that when the condition is diagnosed the swelling should be cut down on from Scarpa's triangle by an incision an inch and a half to the inner side of the femoral artery, the pectineus muscle being either divided or retracted.

My patient, an old woman of 75, came up in March, 1921, complaining of symptoms of acute intestinal obstruction. She had been ill for four days. There was no pain, and no swelling over the obturator region. On opening the abdomen a knuckle of gut was found tightly strangulated in the obturator canal. I reduced it and buried a small gangrenous area by a purse-string suture, but did not attempt to close the canal as she was very ill.

She came up again, sent by Dr. Angell James, in January, 1923, with a recurrence of the condition, this time on the third day. Again there was no pain down the leg and no swelling, but in view of the previous history the diagnosis was obvious. I again opened the abdomen without much difficulty, pulled out the small intestine which was snared in the opening, and ascertained that it was not gangrenous. About half the diameter of the gut was nipped; it was a Richter hernia. The patient was then placed in the Trendelenburg position, and it was found that the hernial canal was about two inches long, of uniform calibre, and just admitted the finger. The position of the vessels and nerve was not identified. I made a small incision over the lower rib cartilage, excised a piece of cartilage corresponding in length and thickness to the capacity of the canal, and inserted it into the obturator canal; by means of a purse-string suture I drew the peritoneum together so as to close the canal over the piece of cartilage, which completely filled it. All this only took five minutes. She made an uninterrupted recovery in spite of her 77 years.

Herniotomy from the groin must surely be very difficult, especially in an aged patient acutely ill. If the bowel lies between the layers of the obturator muscle, it would be more difficult still. Then there is the grave uncertainty as to where to cut to free the strangulation without dividing the artery and nerve. If gangrene is found it will be necessary to open the abdomen to repair it. Difficult surgery is generally dangerous surgery.

It would appear, therefore, better practice, even when the condition is diagnosed, as it was on the second occasion in my patient, to perform laparotomy and use the Trendelenburg position. Perhaps the hernia will be reducible without cutting the neck of the sac; if it has to be cut the surgeon may be able to see and avoid the artery, and even if it be divided there will be no difficulty in securing it. The bowel can be examined for gangrene, and treated if necessary. The only risk is that dirty fluid from the sac may get into the peritoneal cavity; probably a little does so even if the hernia is reduced from without, and it can be guarded against by careful packing and mopping.

As my case shows, an attempt ought to be made, in favourable circumstances, to close the canal, or there will be recurrence. It would be easy to do so by a purse-string suture through the peritoneum, but it is doubtful if that will be effectual when, as in my case, there is an open canal, with firm walls, inviting the peritoneum to stretch and form another sac. The peritoneum is very loose at this point. To close the canal by suture of the obturator muscle is difficult; it will not yield easily and it has to be sewn to bone or periosteum. The nerve might very likely be included and give rise to persistent pain. When the size and shape of the canal is suitable, and the contents not noticeably septic, the introduction of a piece of rib cartilage seems to be quick, safe, and effectual. Cartilage needs a very small blood supply, and can readily unite with fibrous tissue to form a firm resistant mass.

THE late Mr. Joseph Constantine, shipowner, of Northallerton, has by his will bequeathed £1,000 each to the North Riding Infirmary and the Cottage Hospital, North Ormesby, and £500 to the Rutson Hospital, Northallerton.

THE trustees of the estate of Mrs. Constance Armstrong, who bequeathed a large part of her fortune to cancer institutions, have allocated £1,600 each to the Imperial Cancer Research Fund, the Cancer Hospital, Fulham Road, London, the Cancer Charity, Middlesex Hospital, the Liverpool Hospital for Cancer, and the Caird Cancer Ward of the Dundee Royal Infirmary; also £1,000 to be used on behalf of cancer cases at the Royal South Hants Hospital, and £1,500 for the same purpose at the Royal Victoria and Albert Hants Hospital, Boscumbe.

## Memoranda:

### MEDICAL, SURGICAL, OBSTETRICAL.

#### ACUTE OBSTRUCTION BY MECKEL'S DIVERTICULUM WITH SYMPTOMS RESEMBLING APPENDICITIS.

The following case seems to me worthy of record as showing that in acute abdominal conditions a mid-line incision must always be the safest; otherwise, as indeed in this particular case, serious lesions might easily be overlooked.

On September 13th, 1922, W. C., aged 16, was seized at 9 a.m. with severe abdominal pain causing vomiting; the pain lasted for an hour and then ceased. The boy returned to work, but as the pain returned in two hours he went home. The mother obtained medical advice, and the doctor, after seeing the patient twice within four hours, sent him into the hospital as a case of appendicitis for urgent operation. I saw the patient at 9 p.m.; the temperature was 101.4°, and the pulse 88. He had vomited twice, and his bowels had been naturally opened twice during the day. There was much tenderness and rigidity over the right iliac fossa, and for an area of 3 inches diameter about the umbilicus; the rest of the abdomen was fairly soft. At this time the patient did not appear to be suffering much pain, nor was his expression anxious. The symptoms and physical signs pointed to acute appendicitis in an early stage. In operating on women it is usual to open in the paramedian right or median line, having regard to possible complications (pyosalpinx, twisted ovary, etc.), as the incision can be easily enlarged. In this case, however, dealing with a boy, and being, moreover, fairly sure of the diagnosis, I used a "gridiron." On opening the peritoneum a good deal of clear fluid escaped. I pulled out about 3 inches of small bowel which was very blue and congested. Quickly realizing that appendicitis was not the trouble, I closed the first incision and opened in the mid-line. I found acute strangulation of the small bowel by a strong band of adhesions from a Meckel's diverticulum. This diverticulum had a base 1½ inches broad at its opening from the bowel, was 4 inches long, conical, and tapering to a point. From this point extended a band about 8 inches long, which had become attached to the mesentery in two places. Between the two attachments three coils of small bowel had pushed their way and become tightly constricted. Fortunately it was not yet gangrenous, and I was able to remove the adhesions, resect the base of the diverticulum, and sew up the hole in the bowel transversely without soiling the peritoneum. The wounds healed by first intention; the boy made an uninterrupted recovery, and left the hospital on October 6th.

JOHN W. HEERES, M.B., B.S. Lond.,  
Surgeon, the Royal Hospital, Richmond.

#### MENINGITIS DUE TO PFEIFFER'S BACILLUS.

I AM prompted to send the following report by two notes in the BRITISH MEDICAL JOURNAL of March 10th (p. 416, and *Epitome*, No. 210) on cases of meningitis due to Pfeiffer's bacillus.

On February 12th I was called to a girl child of 18 weeks, suffering from what was apparently a simple gastro-intestinal disturbance with vomiting, and slight diarrhoea with green curdy motions. Two or three days later the diarrhoea had given place to constipation, and there was noticeable a peculiar listlessness. The child did not appear very ill, but cried less, and was generally quieter, than is usual in such a case in an infant. Shortly after—I cannot state the exact date—I noticed that the anterior fontanelle was somewhat turgid, but examination revealed no other sign of meningitis.

On February 20th the parents requested a consultation with my colleague, Dr. C. P. Strong, and at this examination there was demonstrable a very slight rigidity of the hamstrings, but no other sign of meningitis. The next day there was no hint of Kernig's sign, but the bulging of the fontanelle was more noticeable, and I observed a slight transient divergent squint, though at the time I thought this was very probably nothing more than the strabismus one so frequently sees in a young baby.

I performed lumbar puncture at 11 a.m. I thick yellow pus—so thick that it was rough noted only pus cells and a few large lymphocytes; no micro-organisms were found, but the examination was somewhat cursory. I sent the pus to the Clinical Research Association, and received two reports—the first to the effect that a very few Gram-negative bacilli were seen in stained films, and the second that these organisms gave the cultural and morphological characteristics of Pfeiffer's influenza bacillus.

The child died on February 22nd—the eleventh day after it had become noticeably ill; it had been apparently almost unconscious for about thirty-six hours.

It is noteworthy that in this case of what was seemingly a primary infection of the meninges by Pfeiffer's bacillus—

1. The onset resembled in all particulars the gastro-intestinal disturbance frequently seen in a hand-fed baby whose meals are regulated largely by the mother's whim or its own cries.

2. The bulging fontanelle was the only persistent sign of meningitis; and, apart from a transient Kernig's sign and a still more transient squint, there were no signs of meningeal involvement. The complete absence of head retraction was particularly noticeable.

Boston, Lincolnshire.

E. N. BUTLER, M.B., B.Ch.

## Reports of Societies.

### CORONERS' INQUESTS: ANAESTHETIC DEATHS.

AN animated debate took place at a meeting of the Section of Anaesthetics of the Royal Society of Medicine on April 20th on the subject of coroners' inquests on deaths under anaesthesia. Dr. A. L. FLEMING was in the chair, and the meeting was attended by representatives of the Medico-Legal Society and the Coroners' Society.

Dr. J. H. CHALDECOTT, who opened the discussion, said that it had been laid down recently by a critic in the lay press that deaths under an anaesthetic belonged to the category of violent or unnatural deaths upon which a coroner was required, under the Act of 1887, to hold an inquest. The speaker maintained, on the other hand, that in view of the attitude of coroners towards other surgical deaths it was not obvious that all anaesthesia deaths were unnatural, and, further, that it would be to the public advantage if inquests were not held on all anaesthesia deaths as a matter of routine. Their work as anaesthetists left them nothing to conceal, and the discussion of this subject was not prompted in the slightest by antagonism to coroners. If it could be shown that the holding of these inquests as a matter of routine added to the safety of the community, it would be for the medical profession to endure in silence any strain or inconvenience which such inquiries imposed. But deaths which occurred from purely surgical complications, even in operations of expediency, were not made the subject of coroners' inquests—a course which he regarded as perfectly right and proper, but which left him wondering why coroners did not exercise the same discretion in the case of anaesthesia deaths. The reason why deaths from surgical shock were not made the subject of inquests was because it was believed that the surgeon performed the operation for the patient's good, and with the patient's consent, and that to undertake the operation was part of his duty as a qualified practitioner. But the same considerations applied to the administration of the anaesthetic.

The only advantage which the present system conferred on the public was the satisfaction which it gave to the friends of the deceased to have things cleared up; the same thing might apply to all deaths occurring under medical treatment when the relatives were dissatisfied, or when information had been given which led the coroner to suspect that there might have been negligence, carelessness, or irregularity. On the other hand, the public was disadvantaged by newspaper reports of inquests, which were read by people who did not realize that the fatalities represented an infinitesimal proportion of the cases in which anaesthetics were administered. The publicity thus given caused patients to postpone necessary operations; it added to their anxiety when the operation at length became inevitable; and it meant a further tax upon the nerves of the medical man in charge, especially if he were a man on the threshold of his career. The anomaly was that if the surgeon and anaesthetist shirked their duty and allowed the patient to die without operation the death would be classified as natural; if they strained every nerve to save the patient, and yet he died on the table, the death would be accounted violent and unnatural. Well might Shakespeare say:

"But is this law?"

Ay, marry, is't; crowner's quest law."

It was difficult to understand why, unless there was *prima facie* evidence of neglect or carelessness, such a death, even in operations of expediency, should be regarded as more unnatural than any sudden death under medical treatment. No wonder that the administration of anaesthetics was the least popular of a doctor's duties.

An aged man died during operation after having been under the anaesthetic for some time; the autopsy disclosed well marked fatty degeneration of the heart. In this case the *post-mortem* examination without a public inquest should have been quite sufficient, whereas the inquest led to a sensational report in the evening papers with the alarmist heading: "Operation Risk:

Heart Disease that Escapes Diagnosis." On the other hand, a death due to the fact that the afferent and efferent tubes of the chloroform apparatus had been transposed was an accidental death, and clearly a case in which an inquest was called for.

It was common knowledge that the mortality following surgical operations was diminishing. But would surgery have shown such steady progress had every surgical death been made the subject of a public inquiry? The effect would have been disastrous and would have hampered progress. Imagine the relative merits of two methods of operation being thrashed out in the coroner's court! Similarly the selection of a particular anaesthetic could not be judged by question and answer before such a tribunal. The impressions conveyed to the lay mind by discussions at inquests on the relative safety of chloroform and of ether were almost invariably misleading. The critical attitude of some coroners towards chloroform was already beginning to cramp the teaching of chloroform administration in the hospitals. An unqualified expression of opinion in court that ether was safe and chloroform dangerous was quite inaccurate; in the hands of some administrators and in the case of certain patients the position might be the very reverse. There could be only two reasons for such inquiries: (1) to find out whether blame attached to anyone for the death; (2) to elicit some clinical fact which might be of assistance in preventing future mortality. The first was the primary function of the coroner's court, but it need not be exercised unless there was ground for suspicion. For the second the coroner's court was the worst possible tribunal. As a positive contribution to the discussion, Dr. Chaldecott suggested that a committee should be set up, under a Government department, which would have power to call for all records—clinical, operative, and post-mortem—relating to deaths under anaesthesia. This committee, which would sit in private, would at the end of each year issue to the General Medical Council a report which would be published in the medical press. Alarmist reports in newspapers would be eliminated by entrusting the inquiry into anaesthesia deaths to such a body, and this very absence of publicity, as well as the scientific competence of the tribunal, would be a safeguard to the public. The interests of the public were really interwoven with those of the profession in this matter, and he believed the public would welcome the reform of the present system, which, however well adapted for inquiry into murders, suicides, accidents, and treasure trove, was quite unsuitable in the majority of cases for inquiry into deaths under anaesthetics.

Dr. A. L. FLEMING pointed out that coroners' inquests might work to the disadvantage of the public. The constant thought of such inquests might lead to the choice of an anaesthetic which, while perhaps more immediately safe, was not ultimately the best for the patient. The risk of death at the table might be slightly lessened at the cost of a higher mortality afterwards.

Dr. HAMILTON BEATTIE gave particulars of two typical cases. One was a case brought into the theatre almost in a moribund condition. On opening the peritoneum the patient collapsed, respiration ceased, and the pulse became imperceptible. Heart massage was applied and adrenaline administered direct into the heart muscle. The heart started again, but immediately after the operation the patient developed Jacksonian epilepsy, had a continuous series of fits, and died within two hours. The coroner did not see fit to inquire into that matter at all, yet that was a case in which an inquiry might have been useful to discover why the patient had been allowed to get into that condition before being referred to the hospital. The other case was one of hopelessly incurable carcinoma of the lower jaw on which the surgeon wished to operate with a view to increasing the patient's comfort and relieving an imminent rupture of the carotid artery. The patient lived only three hours after leaving the operating theatre, and in this case, unlike the other, there was an inquest which, so far as he could see, failed to serve any particular object. There was a necropsy which sufficiently showed the cause of death.

Dr. ZEBULON MENNELL said that there were two classes of deaths under anaesthesia: those due to the anaesthetic, and those due to the disease for which the operation was being performed. At St. Thomas's for the last seven years a subcommittee, appointed by the general staff committee, and consisting of a surgeon, a pathologist, and an anaesthetist, had investigated every death occurring in the hospital under an anaesthetic. The anaesthetist concerned had to answer certain definite questions on a form, which was sent to the members of the subcommittee, who met as soon as possible

to discuss the case. It was astonishing in how many of these cases the death was found to have had nothing to do with the anaesthetic, though there were some cases in which the anaesthetic played the principal part. One necessary precaution to take in all such inquiries was to conduct them in such a way as not to make the house-surgeons, the casualty officers, and the resident anaesthetists more nervous than they were already.

#### Coroners on the Existing Law.

Dr. EDWIN SMITH (coroner for North-East London) felt strongly that the anaesthetist did not as a rule receive appreciation from the public—nor always from the coroner's court—for the extraordinary responsibility and difficulty of his position. A coroner might or might not have an expert knowledge of anaesthetics, and might not be able to put the case fairly before the jury, if there was a jury. Coroners' juries were not always particularly intelligent; one jury returned the verdict "Death due to medical evidence!" But the coroner was bound to hold an inquest by the Coroners' Act, 1887. The comparison between deaths from surgical shock and deaths from chloroform anaesthesia was not a true analogy. If the patient died from inhaling chloroform or ether that was a death from poisoning and must be investigated under the present law. It was not always disadvantageous to have a public inquiry. Suspicious or indignant relatives often were satisfied by the time the inquiry ended, and the anaesthetist sustained his reputation. Investigation by a scientific committee would be useful in some respects, but he had not thought out all its practical bearings.

Dr. H. R. OSWALD (Coroner for Western District of London) said that coroners were by no means anxious to hold inquiries into deaths supposed to be from anaesthesia, but it was their interpretation of the present law that such inquiries must be held. The lines which Dr. Chaldecott had quoted from Shakespeare in derision of the "crown's quest" were put in the mouth of a clown. These inquiries on the whole were advantageous to the reputation of the medical profession and of anaesthetists in particular. If private inquiries only were held, people would have the uneasy feeling that something was being hushed up. He agreed that press reports of inquests would often be better suppressed. In 1922 in his own district 925 inquests were held, and in 25 cases the deaths had taken place under an anaesthetic. In not one of these cases was the anaesthetist to blame, but had it not been proved publicly that the anaesthetist had shown the utmost skill some people might have continued to regard him with grave misgiving. A public inquiry was a greater safeguard than an expert inquiry in camera.

Dr. JOSEPH BLOMFIELD said that the coroners had not cleared away the inconsistency that, while a death under an anaesthetic was regarded as unnatural because poison had been administered, a death resulting a few days later from the application of the knife was not so regarded.

Dr. OSWALD reminded the speaker that the late Mr. Troutbeck, coroner for Westminster, used to hold inquests on all operation deaths, and there was a great outcry about it.

Dr. BLOMFIELD said that it was equally undesirable to hold inquests on all patients who died after the administration of an anaesthetic. The complex nature of the deaths occurring during anaesthesia had already been pointed out; it was often difficult to decide to what exactly death was due, but the coroner's court was not the place in which such a complex scientific problem could be solved. Death might be partly caused by the anaesthetic and partly by the patient's condition or the nature of the operation, or it might be due to some surgical misadventure, or to such a thing as the sudden rupture of a small aneurysm in the neighbourhood of the heart. The coroner's court was not the place in which such things could be thrashed out.

Dr. M. I. FINCANE asked what death certificate could possibly be given in cases of this kind if an inquiry were not held. Was it not one reason for these inquiries that the profession had not arrived at any very definite conclusions with regard to the respective merits, the dosage and so forth, of anaesthetics? That was a matter of public interest. The coroner's court of which he had most experience was a model of scientific and legal inquiry, and the coroner himself was a distinguished lawyer and a medical man. There were many reasons why the present law should not be altered.

#### The Pathologist's Point of View.

Sir BERNARD SPILSBURY said that the anaesthetist had spoken under some misconception. The coroner was not

to act on any notice he received as to deaths occurring during anaesthesia, and unless he was satisfied by preliminary inquiry—as in the nature of the case he hardly could be—that the death was natural, he had to hold an inquest. The object of the inquest was to ascertain whether the deaths were or were not unnatural. In a proportion of cases the deaths were natural. The patients died from their disease, independently of the intervention of surgeon or anaesthetist. Sometimes the occurrence of a pulmonary embolism on operation caused instant death, and the coroner's verdict was "Death from natural causes." If the death was unnatural the conduct of the surgeon, his assistant, and the anaesthetist came under review. There was a class of cases in which death could not be entirely dissociated from the administration of the anaesthetic. The part which the anaesthetic played varied with the case. Sometimes the patient was moribund when the anaesthetic was administered. Sometimes the patient was suffering from acute general peritonitis, or in the last stage of intestinal obstruction, and the surgeon and anaesthetist might well hesitate over any intervention. In these cases the anaesthetic might and probably did play some part, although a minor part, in accelerating the patient's end. There were various classes of cases which might be eliminated from the scope of a coroner's inquiry, but, of course, until the inquiry took place the coroner could not discriminate. A certain number of deaths under anaesthetics occurred in subjects who were apparently in good general health. Here it was very difficult to say that an inquiry should not be held. Sometimes they occurred among children, apparently healthy, brought for some minor operation, such as for tonsils and adenoids. An immediate inquiry was called for in these cases. The effect of not holding an inquiry would be to have letters in the newspapers, presenting the facts perhaps in a perverted form. A private scientific inquiry might do much good and add to the common knowledge, but he was afraid it would never replace entirely the public inquiry in the coroner's court. The disadvantage of the coroner's inquest was not in the inquest itself, but in the newspaper publicity which followed and which often took the form of unfair comment. Some newspapers preferred to satisfy the craving for excitement rather than to serve the interests of truth. He suggested that perhaps the coroner himself might prevent this undesirable publicity by issuing a statement to the press in any exceptional case.

In the course of some further discussion Dr. H. P. CRAMPTON pointed out the difficulty in which the anaesthetist might be placed if, in speaking up in his own defence, he had ever to incriminate the surgeon. Dr. F. S. ROOP thought that the Society ought to make an effort to get the Coroners Act altered; all anaesthetic deaths should be inquired into by a small body of skilled and expert people. Mr. CECIL ROWSTREE discussed the relative responsibility for deaths under operation of the surgeon and the anaesthetist.

At the end of the meeting a letter was read from Dr. F. J. WALDO (Coroner for the City of London and Southwark) in which he said that he failed to see how a death caused by a toxic anaesthetic such as chloroform could be other than unnatural and violent, thereby coming under Part I, Section 3, of the Coroners Act, 1887. He repeated some recommendations which he made in an article in a medical journal fifteen years ago, the effect of which was to maintain or even strengthen the rôle of the coroner in this matter. A letter was also read from Mr. Isaac Bradley (Coroner for Birmingham) pointing out that as the law stood the coroner was bound to hold inquests in these cases, but he thought that the coroner should be given discretion to hold inquests or not, and that in many cases he could satisfy himself by private inquiry.

### THE SURGERY OF THE PROSTATE.

A MEETING of the Cardiff Medical Society was held on April 10th, with Dr. E. E. BRIDGLEY in the chair, when a paper, entitled "The surgery of the prostate," was read by Mr. T. E. HAMMOND.

Mr. Hammond said that the simple or senile enlargement of the prostate was probably due to a perversion of the normal evolution which occurred in the male sexual organs after the age of 45, and corresponded to the sero-cystic disease of the female breast. The trouble to which an enlarged prostate might give rise could be regarded from three points of view: (a) Changes in the tumour itself;

(b) secondary effects on the urinary apparatus; and (c) the symptoms and complications.

(a) Malignant disease might arise in the sexual organs after the age of 45, especially if any abnormal evolutionary condition was present. The enlarged prostate formed no exception, and about 16 per cent. of tumours removed as simple adenomata showed malignant changes.

(b) The obstruction to the outflow of urine led to dilatation of the bladder and later of the ureter and pelvis of the kidney. This gave rise to back-pressure nephritis with retention of urea in the blood, a raising of the blood pressure, and arterial changes. An impairment in the general health and the mental faculties soon followed. This interference with the function of the kidneys constituted a great danger, since uraemia was usually the cause of death.

(c) Difficult micturition was often annoying, and frequency, especially when combined with urgency, might be distressing. When present at night it disturbed sleep and when present during the day it might prevent the carrying out of social duties. The chief complications were acute retention and infection.

As regards treatment, urinary sedatives had a temporary effect on the symptoms, but did not prevent the insidious destruction of the kidney tissue. Extract of the prostate or of the endocrine glands was useless. X-rays and radium had their advocates, but it was difficult to understand why they should have an action on such a deeply situated organ as the prostate when they had failed in similar conditions found in the more superficial organ, the breast. The results claimed were due probably to a failure to recognize the irregular course which so many of those cases ran, for there might be complete remission of symptoms apart from any treatment.

Three methods of treatment were available—(1) the use of the catheter, (2) forage of the prostate, or (3) removal of the prostate.

1. Catheter life was painful, gave only slight relief, and at any time operation might become imperative. It should never be started with the idea of operating later if it failed, for infection of the urinary tract, one of the chief causes of the post-operative mortality, would have been set up. It should be reserved for cases where operation was refused or was contraindicated by some other disease.

2. Forage, the term applied to the formation of a channel through the prostate, had been revived lately through the introduction of the Brown-Bueger cysto-urethroscope and diathermy. It was only of slight value when the lateral lobes were enlarged; but when there was enlargement of the middle lobe alone and the obstruction was localized to the neck of the bladder, the functional result was often good.

3. Suprapubic prostatectomy gave a perfect functional result. The mortality rate was 8 per cent. for hospital patients and 3 per cent. for private patients; such figures could be attained only by regarding the actual operation as but a stage in the procedure and by considering the pre- and post-operative treatment as being equally important. The operation, a major one in men of 65, would always have some mortality; most of the deaths to-day were due to uraemia and the lighting up of a pre-existing infection of the urinary tract, two causes that could be prevented by earlier operation. Against this mortality must be weighed the inconvenience and dangers of the enlargement. The symptoms tended to become worse, and at any time retention and infection might set in.

The open operation as practised by Sir John Thomson Walker was the procedure of choice, but where the general health was not good Mr. Hammond performed the older method. When signs of renal inefficiency were present, revealed by the general condition or by the function tests (of which the best were the blood urea and the urea concentration tests), the prostate should be removed only after preliminary drainage of the bladder. Suprapubic prostatectomy should be reserved for the simple or so-called adenomatous enlargement; it should not be performed where the prostatic symptoms were due to some other affection of the gland, such as malignant or chronic inflammatory prostate.

### Instruments for High Microscopical Magnifications.

Dr. JAMES BEATTY gave a demonstration of new instruments for obtaining high microscopical magnifications. He demonstrated two eyepieces of his own invention which were infinitely variable in power within their upper and lower limits, but they could be usefully employed only if the capabilities of the microscope were thoroughly understood, as no microscope could show anything of smaller diameter than half a wave-length of the light used. The new eyepieces shown were meant to be used only on the critical image, and the merit claimed for them was that a microscopist possessing one or other of them and Nos. 2 and 4 eyepieces (and an extra No. 2 in the case of one of the new instruments) could obtain any magnification whatever producible by eyepiecing from about  $\times 9$  to about  $\times 40$ . By working with the critical image and varying the power of the eyepiece as required within the limits that the image would stand, much of the work at present done with an oil-immersion  $1/12$  in. could be done with a  $1/6$  in., thus avoiding the "messiness" of the oil.

## ABNORMAL FINDINGS IN BLOOD AND EXCRETA.

THE last pathological meeting of the session of the Liverpool Medical Institution was held on April 5th. After the exhibition of specimens and a short discussion Dr. E. CRONIN LOWE read a paper on the significance of abnormal findings in blood and excreta of chronic cases.

Dr. Cronin Lowe showed schemes of general bacteriological and pathological examinations employed in the investigation of obscure cases of various kinds, including bacterial examinations of the various respiratory passages, intestinal canal, and urine. Blood examinations should be cytological, biological, and biochemical, blood urea, uric acid, alkalinity, alkali reserve, and chloride contents being most essential, and to a lesser degree calcium, lipid, and creatinine estimations. Gastro-analysis, alveolar air analysis, with a full faecal and urinary analysis in certain cases, also played an important part in working out the metabolic efficiency or evidence of infection. In the blood examinations the methods of Maclean, Myers, and Fine were chiefly followed. A series of illustrative cases showed that in addition to definite nephritic types and typical glycosuric and diabetic cases there existed a large number of chronic conditions, clinically grouped under many different diagnoses, which showed more or less abnormality either as regards renal or pancreatic function, or both. Maclean's urea concentration test and, in certain cases, the comparative estimation of uric acid in blood and urine, was of value in the diagnosis of early nephritic changes. In cases of intestinal toxæmia Dr. Lowe suggested that the variations in blood and urine of the diastase and sugar contents were related to the degree of hepatic or pancreatic disturbance due to intestinal infection through the portal or lymphatic systems. Such findings were often obtainable in cases that clinically gave no evidence of pathological changes in the digestive complex represented by stomach, liver, biliary passages, and pancreas, thus proving early functional derangement and enabling prophylactic treatment to be commenced before gross pathological damage had been inflicted. Dr. Lowe indicated the value of successive blood sugar estimations after a definite meal in the detection of foci of infection in the body, and this method might be used in controlling treatment. Finally, he insisted that in any chronic case the important point was the presence or absence of an effective resistance. As it was very probable that natural immunity was largely associated with a normal metabolism and endocrine response to infection, the improvement of a deranged metabolism would certainly make for the more speedy recovery of an infected case. In this fact lay the special value of these somewhat extensive pathological examinations.

Discussing the paper, Dr. COOPE spoke of the great need for further work in correlating these tests with the clinical deductions it was permissible to make; Dr. DINGWALL FORDYCE said that pending further work the judgement of clinical experience was still supreme; and Dr. PEMBERTON gave his experience of the variations in gastric hydrochloric acid in cases other than those of gastric origin.

A MEETING of the Bath Clinical Society was held on April 6th, with Mr. W. G. MUMFORD, the President, in the chair, when a discussion was held on indigestion, its varieties and treatment. The discussion was opened by Dr. C. S. FLEMING, from the point of view of the general practitioner. He dealt with the problem of pain, which was so often complained of by patients and so difficult to explain, and also discussed the efficacy of diets and the administration of alkalis. Dr. F. G. THOMSON continued from the standpoint of the physician; he defined the term "indigestion" as a condition involving pain, eructation of gas or sour fluid, and vomiting, and discussed the treatment both by general means and drugs. He pointed out the association of dyspeptic symptoms with oral sepsis, pulmonary tuberculosis, and cardiac disease. Mr. FRASER, who spoke from the standpoint of the surgeon, remarked on the failure to diagnose cancer of the stomach in the early stages. He then dealt with the unreliability of the various methods of diagnosis of the various surgical conditions showing symptoms of dyspepsia. The discussion was continued by Dr. EDE, Dr. MARSH, Dr. MITCHELL, who dealt with duodenal ulcers; Dr. HEATHCOTE, Dr. R. G. GORDON, who dealt with dyspepsia of psychogenic origin; Mr. NIXON, Dr. COATES, and Mr. C. H. TERRY.

## BRITISH CONGRESS OF OBSTETRICS AND GYNAECOLOGY.

### MEETING IN EDINBURGH.

THE fourth British Congress of Obstetrics and Gynaecology was held in Edinburgh at the end of last week. On the first day, April 19th, both the morning and afternoon sessions were given to a discussion on intrinsic dysmenorrhœa. The meeting was held in the hall of the Royal College of Surgeons, and the chair was occupied by Dr. LAMOND LACKIE, President of the Edinburgh Obstetrical Society.

#### INTRINSIC DYSMENORRHOEA.

Professor BLAIR BELL (Liverpool), who opened the discussion, defined intrinsic dysmenorrhœa as the pain due to some inherent abnormality in the structure of the organs of menstruation or in the physiological processes connected with that function. "Extrinsic dysmenorrhœa," on the other hand, denoted the menstrual pain due to the presence of acquired pathological lesions in or in the neighbourhood of the pelvic genital organs.

Dr. Blair Bell analysed 1,000 cases of intrinsic dysmenorrhœa (400 private and 600 hospital); as few of the patients had sought advice because of dysmenorrhœa the records were only of value for the purpose of studying the pathology of the condition. The average age at the time of consultation was 33 and 35½ years respectively; in 46 per cent. and 43.5 per cent. respectively the onset of the dysmenorrhœa was primary, and in 5 per cent. and 6 per cent. secondary.

#### Nature and Frequency.

In intrinsic dysmenorrhœa the pain might be pre-menstrual or intra-menstrual, or both; very rarely was it post-menstrual. The pre-menstrual variety was due either to painful ovulation or to engorgement of an underdeveloped fibrotic uterus. It was rarely severe, was aching in character, and might extend to the sacral region. The intra-menstrual variety was due to uterine colic caused by irregular waves of contraction in an underdeveloped uterus, or to the colic produced during expulsion of intrauterine clots. As there was no standard to measure the severity of pain, individual tolerance was liable to influence any statistical study. He had found intrinsic dysmenorrhœa three times as frequent as extrinsic (50 per cent., as compared with 17 per cent.). Secondary intrinsic dysmenorrhœa was very rare.

#### Period of Onset; Classification of Cases.

Primary dysmenorrhœa might be defined as menstrual pain coincidental with the onset of menstruation; but as girls usually menstruated without pain on the first few occasions it was more convenient to include all cases in which the pain commenced during the first two years after puberty. Among 274 private patients the onset was primary in 67 per cent. and secondary in 7.5 per cent.; among 379 hospital patients it was primary in 69 per cent. and secondary in 9.5 per cent. There were no cases of extrinsic dysmenorrhœa. He classified cases of intrinsic dysmenorrhœa into those showing—

1. Morphological anomalies—namely, (a) underdevelopment of the uterus with normal shape; (b) under or full development with or without underdeveloped ovaries, with a conical cervix and phallostoma; (c) under or fully developed uterus with acute flexions (cochleate uterus); and (d) those showing gross malformations such as double uterus, atresia of cervix or vagina, or accessory occluded uterine cavities.

2. Physiological abnormalities, such as intrauterine clotting of menstrual blood, and excessive exfoliation of the endometrium—membranous dysmenorrhœa.

The importance of pregnancy as a curative factor had been overestimated; only half of his private cases and about one-third of his hospital cases had been cured in this way, though the hypertrophy of the muscle fibres during pregnancy leading to the full development of the uterus played an important part in the cure of certain cases.

#### Clinical Aspects.

A slight degree of underdevelopment of the uterus was probably the most usual causal factor in intrinsic dysmenorrhœa. The ovarian hormone might be capable of stimulating menstruation from an incompletely developed uterus. The length of the uterine cavity measured with the sound was in most cases practically normal. The body, however, might be underdeveloped and the length chiefly due to the cervix; it

the body were of normal size and menstruation scanty it pointed to underdevelopment of the ovaries. In such cases the prognosis was not good. With full development of the ovaries and a moderate degree of underdevelopment of the uterus the outlook was fairly good if the patient were under 20 years old; if over 25 it was only occasionally possible to effect improvement by medicinal means. An attempt should be made to stimulate development of ovaries and uterus by giving 5 grains of whole ovary substance after food three times a day, and 5 grains thyroid substance (B. W. and Co.) at night. If the ovaries were well developed and menstruation normal or excessive thyroid alone should be given. Operative treatment was rarely indicated in this class of case. Derangement of the internal secretions, chiefly of thyroid and pituitary, in early life led to imperfect development of the genitalia. If the disturbance was of minor degree the underdevelopment might not be marked and dysmenorrhoea occurred; if the disturbance was serious amenorrhoea was the usual result. The dysmenorrhoea was therefore the indirect result of thyroid and pituitary insufficiency through the latter causing underdevelopment of the genital organs.

In the uterus with conical cervix and pinhole os dysmenorrhoea was frequently absent. Though the pinhole os might be a bar to conception it was probably only associated with dysmenorrhoea when the uterus was poorly developed. Such cases should be treated by dilatation and posterior division of the cervix, and the administration of thyroid and ovarian substance.

#### *Acute Congenital Flexions (Cochleate Uterus).*

The anterior cochleate uterus was very common, whereas the posterior variety was extremely rare. In the former there was a large quantity of fibrous tissue and in the angle of flexion this tissue was disposed in an intricate interlacing fashion which prevented the anterior wall from developing *pari passu* with the posterior wall, in which the fibrous tissue lay in straight bundles. As a result the posterior wall grew round the anterior and produced this malformation. Dysmenorrhoea in these cases was particularly severe, partly because of the state of underdevelopment with fibrosis and partly because of the interference with the normal peristaltic wave of contraction at the angle of flexion. If the uterus in these cases was well developed dilatation with posterior division of the cervix to increase the possibility of pregnancy was usually sufficient. If it failed anterior hysterotomy should be done. If, however, the uterus was underdeveloped dilatation only relieved partly and temporarily and relapse was inevitable. Anterior hysterotomy should be carried out and followed by thyroid substance. The operation of anterior hysterotomy was described as follows:

The cervix is drawn down with silk threads and the vaginal mucosa with the bladder are separated from the front of the cervix. The anterior wall of the cervix and os internum are divided with scissors, opening the cavity of the uterus. The circular fibres of the cervix retract and the longitudinal fibres are united by interrupted sutures. The flap of mucosa is then replaced and fixed with a few sutures.

Professor Blair Bell deprecated the empirical performance of dilatation, which as a rule only relieved temporarily, and especially dilatation to the extent of division, in which case the laceration of the internal os usually extended into the broad ligament and healed with the formation of scar tissue, which left the patient worse than before. It was much better and safer for the surgeon to look at what he was doing and cut.

#### *Intrauterine Clotting.*

In 1911 he had shown that menstrual blood contained no fibrin ferment; it had been extracted in the passage through the endometrium. His conclusions had been questioned by Whitehouse and others, who contended that the absence of fibrin ferment was due to thrombolytin secreted by the cervical mucosa. When, however, the uterus was removed during menstruation it was not usual to find a clot in the uterine cavity and the blood in a haematometra was unclotted, while amputation of the cervix did not lead to clotting. He was convinced that intrauterine clotting was abnormal and might lead to dysmenorrhoea. In these cases there was free menstruation and often menorrhagia, and the onset of pain coincided with the passage of clots during the menstrual period. He believed the explanation of the clotting to be that, on account of the menorrhagia, the blood passed too quickly through the endometrium to abstract the fibrin ferment. The blood might escape so quickly into the vagina that it did not clot in the uterus; in these cases there was no

dysmenorrhoea, which only occurred if there was intrauterine clotting. Calcium lactate increased the tone of the uterine muscle and decreased the menstrual flow. If it failed dilatation and curettage should be performed in order to remove the thickened endometrium, often present on account of excessive ovarian stimulation. Most cases of secondary intrinsic dysmenorrhoea were due to intrauterine clotting.

#### *Exfoliative or Membranous Dysmenorrhoea.*

Excessive exfoliation of the endometrium did not often give rise to the severe dysmenorrhoea usually ascribed to it. When pain was present it was due to the association of intrauterine clots with membranes which together formed a compact cast. Histologically the cast showed a well defined pre-menstrual decidual reaction of the stroma cells. The menstrual flow was usually profuse, and, the blood being unable to break through the dense decidual barrier, the membrane was stripped off. Treatment should be directed to the control of the menorrhagia usually present and to limitation of decidual reaction. Theoretically calcium salts should restrain the menorrhagia and control the inhibition of fluid by the stroma cells, but in practice this or any other treatment was rarely successful.

#### DISCUSSION.

##### *Results of Operation.*

Dr. R. W. JOHNSTONE (Edinburgh) communicated the results of operation on 575 cases in the practice of Edinburgh operators, of Professor Kynoch of Dundee, and of Mr. Leith Murray of Liverpool. The operation which was practically always performed was dilatation, followed in most cases by curettage. The results were—50 per cent. permanent cures, 33 per cent. relieved, and 17 per cent. total failures. With regard to other methods of treatment, one other operator as well as Dr. Johnstone himself employed stem pessaries, and were both enthusiastic about the results. He preferred the Wylie drain with a small hole in the base, through which a silkworm gut suture could be passed, thus fixing it to the lip of the cervix. If possible, and if the case was perfectly clean, he preferred to keep the stem in for several weeks. Plastic operations found favour with comparatively few, though sometimes the Dudley operation had succeeded where previous dilatation had failed. It was debatable whether the benefit was due to the actual splitting of the cervix or to the latter allowing more complete dilatation of the internal os. No one seemed to have a good word for the Pozzi operation.

Dr. J. E. GEMMELL (Liverpool) defined intrinsic dysmenorrhoea as a functional derangement due to uterine colic produced by a faulty contraction wave in a uterus that was maldeveloped, underdeveloped, and mildly infected. The most frequent pathological complex was probably a functional disturbance in the bipolar action of the uterus, which in the presence of maldevelopment produced abnormal spasm of the internal os; it might be the result of some loss of nervous control acting centrally or to a failure between the longitudinal and circular fibres. As to operative measures, he favoured dilatation of the cervix, to the point of fracture of the circular fibres of the internal os, with curettage, and packing the uterus tightly with gauze, which was left in for forty-eight hours. His results from 350 hospital cases of severe dysmenorrhoea were 44 per cent. permanent cures, 10 per cent. temporary cures (three months to seven years), 30 per cent. relieved, and 16 per cent. total failures.

##### *Effect of Pregnancy.*

Dr. HERBERT SPENCER was not in a position to dispute Dr. Blair Bell's statement that only half the cases were cured by pregnancy. In his experience a large number were not cured but were relieved. He doubted whether any patient was so completely cured by dilatation as to have no pain whatever during menstruation. He did not agree that conical cervix and pinhole os did not cause dysmenorrhoea. He had seen excellent results from Pozzi's operation, and this showed that these conditions did cause pain. He thought the operation of anterior hysterectomy was severe and difficult in a virgin, and saw no advantage in it over the use of the hysterotomy by which the internal os was divided from the inside, or over a so-called "dilatation" by which the internal os was lacerated. No virgin could be dilated beyond 18 mm. without laceration. He had used laminaria tents in a large number of cases, but had now abandoned the method, as one patient so treated got an attack of pelvic peritonitis.

Mr. CHRISTOPHER MARTIN (Birmingham) thought that girls should be brought up on more rational lines; especially should they take more exercise and avoid the use of corsets.

Pregnancy, in his experience, did cure the vast majority of cases when due to uterine causes. The classification of dysmenorrhoeas into intrinsic and extrinsic was not the best. The cases should be classed as intra- and extra-uterine. Appendicitis in childhood was a factor which often gave rise to lesions leading to dysmenorrhoea. Dilatation, with extensive division of the posterior lip of the cervix and suturing the mucosa of the cervical canal to that of the vaginal surface, gave satisfactory results. Anterior hysterotomy would be very difficult to do in a virgin. Drugs were of little use; morphine should be avoided, and alcohol should not be allowed, as he had known cases in which it had led to habitual drunkenness.

#### *The Cochleate Uterus.*

Professor DONALD (Manchester) did not agree with Professor Blair Bell regarding the cause of dysmenorrhoea in the cochleate uterus. In his experience the cervix was small and the body elongated. The pain was probably due to an abnormal endometrium. When curetting the endometrium was often found. Dilatation and curettage gave good results, 82 per cent. being cured or greatly relieved; results were better in cases of acute retroflexion than of acute antelexion. He dilated up to 19 to 20 mm. and used a flushing curette. The intrauterine stem was very satisfactory but required careful observation. It acted by causing atrophy of the endometrium by continual pressure. He did not use tents as it seemed unnecessary.

#### *Results of Treatment.*

Mr. BECKWITH WHITEHOUSE (Birmingham) had included in cases of intrinsic dysmenorrhoea only those in which the pain was so severe as totally to incapacitate the patient and render operation imperative. The number of cases attending the Birmingham General Hospital for relief of menstrual pain had doubled in the last five years. This might be due to psychological causes and part of the aftermath of war. Of 39 patients who had replied to his questionnaire, 10 reported themselves as cured, 22 had been partially relieved, the relief lasting from two months to four years; 7 had no relief at all; dilatation and curettage had been performed in 23 cases, with cure of pain in 6, partial relief in 12, and failure in 5. Division of the posterior lip of the cervix, with curettage, had been done in 6 cases, 2 of which had been cured and 4 relieved for a short time only. Abortion did not seem to relieve the pain, but only a pregnancy that proceeded to term. Marriage relieved the pain in 6 cases out of 14, increased it in 2, and in 6 had no influence. He considered that the passage of clots had very little if any influence on menstrual pain; 50 per cent. of all women habitually passed clots from the uterus into the vagina during menstruation, yet 50 per cent. of women did not suffer from dysmenorrhoea. He did not agree that the arguments set forth by Professor Bell in any way refuted his theories. The composition of the menstrual discharge in the human species could be accounted for on a much simpler hypothesis than attributing to the endometrium any special power of extracting fibrin ferment or fibrinogen. Mr. Whitehouse considered that his theory had the advantage of correlating the facts as observed in the human species with those resulting from investigations in comparative physiology.

Professor R. J. JOHNSTONE (Belfast) said that 90 per cent. of women suffered from more or less discomfort at menstruation, but it should only be called "dysmenorrhoea" if the pain were sufficient to disable the patient even for a short time. He was glad that Professor Blair Bell had swept off the old classification into spasmodic and congestive, and that he had taken pinhole os, conical cervix, and retroversion out of the list of causes, as their association was merely accidental. Childbirth, in his experience, had a greater curative effect than Professor Bell had said. Did he aim at complete disappearance of the pain, or merely at so reducing it that the patient could carry on her occupation with comfort, which was a sufficient test of cure? He hoped that Professor Bell would think as well of his operation of anterior hysterotomy ten years hence as he did now. As regards treatment, the internal os should be dilated and the uterus thoroughly curetted, although he was not in favour of dilating to a very high extent. It was impossible to dilate to over 1 cm. without causing division. He left in an intrauterine pack for three days in order to cause better dilatation of the cervix. He did not use the stem pessary, but had found tents exceedingly useful, and thought their use led to a larger

percentage of cures. He had not found it necessary to use an anaesthetic in order to remove them. They could be withdrawn on the third day without difficulty.

[At this stage the Congress adjourned for lunch, which had been provided by the Edinburgh Obstetrical Society at the North British Station Hotel. The discussion was resumed at 2.30 p.m.]

#### *Prevention and Treatment.*

Dr. T. WATTS EDEN (London) referred to the importance of the "relativity of pain," and said that we should have some standard as to what constituted dysmenorrhoea. The best test was the disablement of the patient from carrying on her ordinary avocation. In his opinion the number of cases of severe dysmenorrhoea was very small. He had had cases watched by keeping them in hospital over one or two menstrual periods. The sister in charge reported on the cases as severe, very severe, etc., and the number of cases suffering from what could be called "severe pain" was extremely small, and very rarely indeed was the pain so severe as to be called "excruciating." All dysmenorrhoeas should really be called intrinsic, which meant "intrinsic to the menstrual process," not merely to the uterus. The uterus, ovary, endocrine, and nervous systems all played a part in the process of menstruation, and dysmenorrhoea might arise from any of these. Matthews Duncan defined dysmenorrhoea as a "disease of the nature of a neurosis in which the spasmodic contractions of the uterus caused great pain." He regarded neuroses as an important factor in causation, and Dr. Eden agreed. The time might come when the cochleate (small ante- or retro-flexed) uterus would be relegated to the same scrap-heap as the pinhole os and the conical cervix. In his experience this type of uterus was exceedingly rare, whereas the antelexed or the ante- and retroflexed uterus was common; but in most cases no local pathological condition could be discovered in the uterus, so that the cause must be outside it and possibly outside the pelvis. Professor Blair Bell had gauged the degree of underdevelopment of the ovary by the amount of the menstrual flow, but other factors were important—such as nutritional condition, occupation, anaemia, nervous disturbances, etc.—and therefore it was not justifiable to say that habitual scanty menstruation meant underdeveloped ovaries and vice versa. We had much to learn regarding the action of the endocrines in menstruation. Dr. Eden said that he had done anterior hysterotomy on twelve occasions and had found it the most difficult operation he had ever tackled, and the result had been no better than those obtained by dilatation. Better attention to the proper physiological development of girls was important in the prevention of dysmenorrhoea. Much benefit would be obtained by attention to general hygiene, attention to bowels, etc., at the time of puberty. Girls should be prepared for the onset of menstruation by careful hygienic measures. There was much need for co-ordinated research on a large scale, especially amongst schoolgirls, regarding the influence of habit of life, amount of work, study, etc., upon the production of dysmenorrhoea. As regards medicinal treatment, he strongly recommended atropine 1/100 grain by the mouth three times daily, given before the period was due, and continued during it till the pain was over. It regularized the functional activity of the unstriated muscle all over the body, including that of the uterus.

Dr. J. S. FAIRBAIRN (London) emphasized the important part played by functional disturbances and by suggestion in the causation of dysmenorrhoea. Civilization prevented reproduction following menstruation as it normally should. Menstruation was talked of as "being poorly," and this suggested illness to the young girl at puberty and later. In St. Thomas's Hospital it had been found that nurses on entering upon their training tended to regard themselves as ill and unfit for duty at the menstrual period, as they had been encouraged to do at home; but after they had found this was not customary they were able to carry on perfectly well. The introduction of anaesthetics had, he believed, diminished the capacity for bearing pain. He thought this psychological element was of far more importance than slight variations in the shape of the uterus, such as those on which Dr. Blair Bell had laid so much stress. Besides, it often appeared that girls, previously healthy, first showed evidence of dysmenorrhoea after an illness or after first coming to town or school. In such cases the shape of the uterus could not have changed. As to treatment, he thought that the suggestive effect of the operation was of more importance than the particular type of operation carried out. He

chiefly dilatation or "divulsion," which did much the same as the anterior hysterotomy described by Dr. Blair Bell.

Dr. HAIG FERGUSON (Edinburgh) believed that practically all cases of severe primary dysmenorrhoea not relieved by general treatment by antispasmodics were associated with underdeveloped uterus (uterus pubescens), generally associated with acute flexions—the so-called cochleate or horse-shoe uterus. The longer the condition lasted the more unlikely was it to be cured. Therefore, in order to get good results, early treatment was desirable. He was inclined to think that underdevelopment of the uterus could be prevented by careful attention to girls at puberty. They should not be pressed too hard, either mentally or physically; women were not well fitted for continuous work; they needed intervals for rest and recuperation, and this was of the greatest importance during the developmental period of their lives. Marriage not followed by pregnancy frequently aggravated the pain. As to treatment, he strongly believed in splitting the cervix in certain cases as an aid to dilatation, not that the splitting in itself was of any great value, but because it enabled thorough dilatation of the internal os to be accomplished without injury. The cervix was afterwards repaired as in Dudley's operation. He dilated with bougies up to No. 12 Hegar, and at the same time stretched the uterine cavity with a Sims three-branded dilator without using the screw. He generally curetted at the same time, but did not think it was always necessary.

Dr. GIBBON FITZGIBBON (Dublin) had long since given up the Dudley operation. He had obtained the best results from dilatation up to a point where there was still resistance and about 2 mm. beyond—about 14 mm. altogether—which resulted in rupture of the circular fibres of the internal os. He thought that pregnancy cured in the great majority of cases of severe disabling spasmodic dysmenorrhoea. Regulation of the general health combined with general tonic treatment should be given a trial before resort was had to operation. He did not think that anterior hysterotomy was desirable.

Professor B. P. WATSON (Edinburgh) laid emphasis upon the importance of putting right any wrong hygienic conditions. There was often a general vasomotor disturbance present, and the pain was of a heavy dragging rather than a spasmodic type. Derangements of the ductless glands were important in causing the condition. In actual severe cases the pain was muscular, and might arise either from irregular contractions of the uterine muscle or from spasm of the muscle surrounding the internal os. Normally the uterus should act in a bipolar fashion, the internal os relaxing when the body contracted. If polarity was absent there was simultaneous contraction of the body and of the internal os. This might account for the sterility, as the internal os failed to relax during spasm. All these cases could be cured by overcoming the spasm of the internal os. He supplemented full dilatation by the glass stem pessary or by packing the uterus with gauze, which was left in for four to five days. Cases in which the pain was due to defective uterine muscle were not cured by divulsion of the cervix, but should be treated by means of thyroid and other general measures. He had found atropine useful.

Dr. BETHEL SOLOVONS (Dublin) said that co-education helped in the normal development of the genital organs. He was surprised to hear that posterior division of the cervix was still done. He had found that it often left a scarred cervix with discharge pouring from it which resulted in lasting sterility. He used metal dilators and tents; the latter often cured where simple dilatation failed.

The CHAIRMAN (Dr. Lamond Lackie, Edinburgh), after summing up the discussion, said that he practically always used a glass stem pessary. It was important to dilate a week or ten days before the period. If there was no pain at the following period the stem was left *in situ* until just before the next period was due. If there was pain at the first period it was removed at once. The results from this method were, he considered, much better than if dilatation alone were used. He thought the operation of anterior hysterotomy was difficult and too severe.

Professor BLAIR BELL, replying to the discussion, said that the operation of anterior hysterotomy was very easily carried out in some cases. He had been doing it since 1905. The circular fibres around the internal os retracted and the longitudinal fibres stood out clearly and could easily be brought together. He defined a cure as *no pain whatsoever*. All others he classed as "improved." In cases of sterility with pinhole os he divided the cervix posteriorly and sutured the

mucous membranes together. Pozzi's operation he had given up as it led to eversion of the mucosa with erosion and discharge.

#### DINNER.

In the evening a dinner was held in the Hall of the Royal College of Physicians. A varied programme of music, vocal and orchestral, was provided, a special feature being the "pipin" in o' the haggis" with due ceremonial, and to the evident astonishment of certain members of the Congress from south of the Tweed. The toast of the King was given by the chairman, Dr. LAMOND LACKIE; that of the visiting societies was proposed by Dr. HAIG FERGUSON, and responded to by Dr. WATTS EDEN and Professor R. J. JOHNSTONE; the Edinburgh Obstetrical Society was proposed by Professor HERBERT SPENCER, and replied to by the President (Dr. LACKIE). A specially interesting feature of the evening was the presence of Dr. BYRON BRANWELL, who entertained the members with some "obstetrical reminiscences." On the motion of Dr. J. S. FAIRBAIRN it was resolved to send the greetings of the Congress to Professor Sir Halliday Croom, who had hoped to be present but had been prevented by indisposition.

(To be continued.)

## Reviews.

### THE MEDICAL ANNUAL.<sup>1</sup>

The appearance of a fresh number of the *Medical Annual* is always an event to be looked forward to, for the summary of the achievements of the year that is past serves as a stimulus to greater efforts in the year that lies before us. And yet, though the impression on the whole is distinctly encouraging, one cannot but experience a feeling of melancholy when, after reading through 500 pages of closely printed matter devoted to the progress in the treatment of disease, one realizes how little is the real advance made, how empirical still are many of our best remedies, how abysmal our ignorance of the etiology of certain groups of pathological affections, and how loose yet is that rapprochement between medicine and science which alone can render possible the perfect comprehension of the ailments of the human body. It is good to be dissatisfied—yes, but it is with our own efforts that we are dissatisfied, not with the *Medical Annual*, which serves as an excellent and inoffensive record of our failure. It tells of strivings of workers at home and abroad to develop fresh methods of diagnosis, sounder indications for prognosis, and more reliable ways for combating the action of noxious agents. Of all these strivings, how many will bear fruit? How many are on the wrong road altogether, are working in a cul-de-sac, are pursuing a phantom, a will-o'-the-wisp, a vain, elusive object whose very existence is merely subjective? These are feelings—involuntary and uncloaked—which arise within us as we peruse a record alike both of man's failings and of his successes.

But it would leave a wrong impression on the mind of the reader if we led him to think that there is nothing of interest or instruction in the volume. On the contrary, there is much of both—so much, in fact, that it is difficult to turn to a single section without finding a tale of endeavour and of some progress in the territory concerned. It would be useless to attempt to review it in the usual way; there is too much, and that too widely diffused over too many subjects, to permit us to convey any adequate idea of the whole. However, we may mention the article on basal metabolism, and the information it contains on a method of examination which is probably destined to play a considerable part in the investigation of the future, and also that on arterial tension by two French workers, describing a new mode of measurement of blood pressure by auscultation. The section on the cerebro-spinal fluid will well repay perusal, and the account of the therapeutic value of puncture of the cisterna magna adopted by certain American workers in preference to the more usual lumbar puncture should be noted. The article on insulin is perhaps not quite up to what one might have expected, considering the importance of this new product of physiology. Part is devoted to the pharmacological assay of the hormone, and part to the clinical results obtained, but very little as to indications

<sup>1</sup> The *Medical Annual*. Forty-first year, 1923. Bristol: John Wright and Sons, Ltd.; London: Simpkin, Marshall, Hamilton, Kent, and Co., Ltd. 1923. (Demy 8vo, pp. xevi+630; 101 figures, 45 plates. 2s. net.)

for its use or its actual method of exhibition. There is a very fair review of the treatment of gastric ulcer from a surgical aspect, suitably relieved by an expression of the author's personal opinions on the subject. The discussion of x-ray diagnosis fills several pages, and relates to examination of the intestinal and urinary tracts, lungs, heart, and bones; amongst the accompanying plates there are two very excellent ones of the spine and pelvis as shown by the Potter-Bucky diaphragm. Tropical medicine is well covered by Rogers, and in this connexion it is gratifying to read of Noguchi's success in the treatment of yellow fever by a serum prepared against the *Leptospira icteroides*.

There is much more that we should like to say about the book, but we have said enough to commend it to those not acquainted with previous issues. It is a collection of writings on a wide variety of subjects which should make a wide appeal to every type of medical man; each will find for himself those topics which exert for him that peculiarly individual appeal inseparable from so diverse a thing as human nature.

### A STORY OF DRUGS.

*The Story of Drugs*,<sup>2</sup> by H. C. FULLER, gives a readable account of the processes involved in the preparation of drugs. The collection of wild herbs and the growth of herbs in drug farms are fully described, and a large amount of information is given concerning the trade in crude drugs. The processes involved in the preparation of medicaments on the large scale are also described, with numerous illustrations. In short the book will give the reader a very fair notion of where drugs come from, how they are collected, transported, and how they are prepared for use in medicines.

Interlarded with this general information we were, however, surprised to find a defence of the so-called patent medicine trade in general, and laudatory references to a variety of nostrums, some of which have been convicted for "misbranding" in the law courts of the United States. A certain amount of rather interesting information is supplied regarding this trade in the United States. The capital invested in this industry in 1914 was, it is stated, more than seventy-one million dollars, and in 1919 was probably over one hundred million dollars. The significance of these figures is emphasized by the further statement that in 1914 the capital engaged in manufacturing drugs and chemicals for the legitimate drug trade was only forty-six million dollars. Eighty per cent. of this powerful secret or patent medicine trade is organized in the Proprietary Association of America, and this association in 1915 published an interesting set of requirements to which all products sold by their members were required to conform. The following are some of the chief rules:

"(1) The preparation must be of such character as may reasonably be expected to bring about the results for which it is recommended. . . . Statements regarding therapeutic effects must neither be obviously unreasonable nor demonstrably false. . . .

"(5) The preparation must not be advertised or recommended as a cure for diseases or conditions which are generally recognized as incurable by the simple administration of drugs.

"(6) The package, either as to wrapper, label, or accompanying literature, shall contain no statement in conflict with the misbranding provisions of the Federal Food and Drugs Act."

The last quoted rule contains, of course, the explanation of all the others. In this country the Government makes no attempt whatever to protect the public from quack medicine vendors, but in America any nostrums offending against the above quoted rules would be liable to be declared misbranded and the proprietor to be fined and forbidden the use of the United States postal service.

In order to obtain an idea as to how strictly the Proprietary Association puts its rules into force we looked up in *Nostrums and Quackery*<sup>3</sup> the history of some of the firms selected for special mention by Mr. Fuller in his book.

Dr. Schenck's Pulmonic Syrup, a seventy-year-old remedy for consumption, the secret of which came from the Shawano tribe of Indians, was found to be a wintergreen-flavoured mixture of saccharin syrups, 96.4 per cent. of the solids consisting of sugars. Mrs. Lydia E. Pinkham's vegetable compound for women was found, when analysed for the British Medical Association,<sup>4</sup> to

contain 19.3 per cent. of alcohol and 0.5 per cent. of solid substances. Swift's Sure Specific was sold until 1919 as a cure for "blood poison," and some years previously the claim was made that it would cure cancer; at present it is chiefly recommended for rheumatism, catarrh, malaria, and skin diseases.

These are some of the quack remedies selected by the author for special laudatory mention, and he further makes the general statement that "legitimate proprietary remedies, as they are now offered to the public, are in the main products representing the highest type of the pharmacist's art."

It is very hard to classify Mr. Fuller's book. If it were published by the Proprietary Association of America we should say that it was a piece of very skillful advertising; but why the editor of the Century Books of Useful Science should publish this sort of stuff we find it rather difficult to understand.

### EPIDEMIOLOGY AND PUBLIC HEALTH.

EPIDEMIOLOGISTS have from time to time adopted various classifications of infectious diseases, and that selected by Dr. VICTOR C. VAUGHAN in his book, *Epidemiology and Public Health*,<sup>5</sup> has a great deal to recommend it. He divides the infections into (1) respiratory, (2) alimentary, (3) parenteral, (4) venereal, and (5) local. The first volume of his work is devoted exclusively to respiratory infections. In the second volume he proposes to deal with the remaining infections, and the third volume will be devoted to administrative action having for its object the reduction of these diseases. In the volume now under review each disease is very fully considered. The history, prevalence (seasonal or otherwise), pathology, symptoms, behaviour, mode of transmission, and control are fully and accurately described, so that a very complete picture is placed before the reader. In a work written by American authors and for American readers the references to incidence, morbidity, etc., are naturally from American sources.

In the chapter on whooping-cough an account is given of a method for controlling this disease put into operation in 1913 by the health officer of Chicago. During the first fortnight of the disease the affected child was kept in the house or allowed access to the yard if not used by other children. During the next three weeks the patient was allowed, if accompanied by an attendant, to go into the streets, provided there was fastened on the sleeve of the outer garment a yellow band two inches wide bearing the inscription, "Whooping-cough," in black letters. The use of public conveyances and entry to places of assembly was prohibited. A table (XXXV) giving the number of cases and deaths from the disease in Chicago in the years 1911 to 1918 does not show any falling off in incidence or in the number of deaths as a result of this procedure. The authors suggest that the death rate from whooping-cough might be lowered if children, but only those in good health, after passing their sixth year, were to be intentionally submitted to infection.

Nearly one-sixth of the volume is devoted to tuberculosis, with respect to which the authors hold very definite views, though these are quite in accord with present-day opinions. Although by no means minimizing the necessity for increased activity in preventing infection they emphasize the importance of preventing the development of latent into open tuberculosis. The eradication of tuberculosis, they say, is bound up with the control of other diseases, with improved housing, with better feeding, with education, with the abolition of poverty, and with the slow evolution of the race. The chapter dealing with influenza contains a mass of extremely valuable information concerning the epidemic of 1918-19. From the tables and charts a very clear idea can be obtained of the extent of the outbreak in America. The book is intended to be not only a textbook but a reference work; the index to the contents is quite inadequate and the book the index to the contents is quite inadequate and the bibliographies at the end of each chapter present many noticeable omissions. There is no reference, for example, to Dr. J. C. McVail's writings on small-pox or vaccination or to Sir German Sims Woodhead's contributions to the literature of tuberculosis prevention. These are matters which might have been noticed if it were not for the painstaking thoroughness of the authors evident on other parts of the volume.

## SURGICAL ANATOMY.

THE *Textbook of Surgical Anatomy*, written by Dr. W. F. CAMPBELL of New York, is now in its third edition.<sup>6</sup> We have examined this book with some care because of its evident popularity on the other side of the Atlantic, and we are frankly disappointed in it.

A good book on surgical anatomy must have as its basis a very wide and detailed knowledge of anatomical structure. We note, however, the statement that "the anterior, the middle, and the posterior cerebral arteries, forming three great trunks, inosculate freely in the pia mater and supply the brain. The smaller cerebral arteries neither give nor receive anastomotic branches but form a terminal circulation." The latter sentence is quite correct, but it is incorrect to say that the three great trunks inosculate freely. The "rule" for mapping the fissure of Rolando on pages 56-57 is incorrect. Laryngotomy is referred to as "tracheotomy" on page 180, but is correctly designated three pages later. Few will agree with Fig. 110, which shows the lung contracted and shrivelled in the presence of a pleural effusion, and on page 228 the apex beat is stated to be "at the upper border of the fifth left costal cartilage," which means, if it means anything, that it is in the fourth intercostal space. We note further that the reader is recommended to try to milk a stone in the common bile duct into the duodenum or crush it *in situ*. In Fig. 189 the letter "D" is used to mark the kidney and also the common bile duct. The anterior layer of the perirenal fascia is shown as passing across the middle line to become continuous with its fellow of the opposite side. Though this disposition of Gerota's fascia is commonly given in textbooks, it is incorrect, for the fascia is interrupted in the mid-line by the primitive mesentery. If the other arrangement were that which really existed perinephritic pus might be expected to track across to the opposite side, but in fact it does not.

The book is well printed and clearly illustrated, although anatomical drawings on top of photographs of the living are never, to our view, satisfactory.

## ST. BARTHOLOMEW'S HOSPITAL REPORTS.

THE first quarterly instalment of this year's volume of *St. Bartholomew's Hospital Reports*<sup>7</sup> opens with an interesting historical article, the previously unpublished journal of a visit to Paris in 1664 by Edward Browne, the eldest son of the famous Sir Thomas and sometime physician to St. Bartholomew's Hospital and President of the Royal College of Physicians. The text is reproduced with the original and to the modern eye quaint spelling—for example, "parancleutisis in ascite"—and gives glimpses of some of the contemporary leaders of the Paris school, such as Guy Patin, whom he regarded as "the maddest fellow for a professor that ever I heard speake, but I was much disappointed in my expectation of understanding all hee said by reason hee used the French tongue so much." The journal is introduced by a short account of the author by Mr. Geoffrey Keynes, the secretary of the Editorial Committee and an authority on Sir Thomas Browne. In his article on the correlation of the clinical manifestations and serological types in pneumococcal infections Dr. R. R. Armstrong continues the work which, as Ernest Hart Memorial scholar, he reported in our issue of February 19th, 1921 (pp. 259-262), and now gives the results of the serological classification of 200 strains obtained from every recognizable clinical manifestation due to a pneumococcus during the years 1920-22. Out of 76 cases of lobar pneumonia 41.5 per cent. were due to type and subtypes I, and 41.3 per cent. to type and subtypes II; this substantially agrees with the original American observations, except that the numerical incidence of type III is lower than in the American figures. The remainder of this instalment of the *Reports* is occupied by five lectures given early in 1922 in a course on diseases of the liver; Sir Humphry Rolleston leads off with a general review of the physiology of the biliary secretion, and perhaps rather encroaches on the domain of Sir F. W. Andrewes, who follows with a lucid account of jaundice and its different types. Professor F. R. Fraser deals with enlargement of the liver as a symptom of disease, and illustrates his subject by an analysis of 32 cases. In discussing

jaundice in children Dr. J. H. Thursfield divides the subject into jaundice in infants under 2 years of age and in older children. Like Dr. E. A. Cockayne in 1912 he believes that catarrhal jaundice and acute yellow atrophy belong to the same category, and are both manifestations, though in different degrees, of an at present unknown infection. In the last lecture Dr. T. H. G. Shore gives a good summary of the pathology of acute degenerations of the liver.

## NOTES ON BOOKS.

WE have received a copy of *The Progress Book*,<sup>8</sup> a little illustrated register for recording the stages of the mental and physical development of the child from birth to the 21st year of life. It has been revised and enlarged for Mellin's Food Company by J. J. PILLEY, Ph.D. On a small scale it represents the kind of medical annuals of the individual which has more than once been advocated by the pioneers of the Infant Welfare movement as desirable for every child in the State—a continuous record of health. It comprises weight charts and other details usually afforded in the case papers of the welfare centre and of the school medical service. Such a record would be useful to members of the medical profession, who usually have to rely for information with respect to past health and illnesses on the often inaccurate and always incomplete anamnesis of the mothers or the patients themselves. Among other details are spaces or papers for preserving photographs and for registering increments in weight, the dates of eruption of the teeth, illnesses, and other important events in the life history of the child. The medical profession for their own convenience should encourage parents to keep registers of this kind.

Dr. OSCAR PFISTER, who is the author of a number of well known works on psycho-analysis, has now written a volume entitled, *Some Applications of Psycho-Analysis*.<sup>9</sup> The book deals with psycho-analysis as a psychological method, and with its relation to art, philosophy, child life, war and peace, and missionary work. The longest and most important chapter is that devoted to a discussion of psycho-analysis and philosophy. The author, who is a pastor in Zürich, concludes his consideration of this problem by expressing the hope that Freud's psycho-analysis, although like the philosophy of Socrates it has not created any new system, will give an impulse to fruitful spiritual movements and revolutions.

The desultory reader, especially if he be one of those who when they hear a new book praised read an old one, already owes much to Messrs. Dent, but will admit his debt to have grown heavier when he has made acquaintance with a volume of the *Bedside Library*.<sup>10</sup> Perhaps the word "heavier" is not quite happy, for the volumes are light, but "larger" would be no better, for they are small. A bookmark has been provided, thoughtfully, for the first patient for whom we prescribed the *Life and Death of Socrates* fell asleep at the second page. *The Life and Death of Sir John Falstaff* is more stimulating; two old Shakespeare students had the happy idea of putting together in some sort of chronological order the scenes from the *Merry Wives*, *Henry IV* (1 and 2), and *Henry V* in which the Knight appears. To some of us Falstaff is the most wonderful of all Shakespeare's creations, so alive is he, so very human, so frail in morals, so mighty in body, so witty in excuse, so sententious and so flippant. The compilation is well done, and is embellished by Sir George Radford's essay, reprinted with Mr. Birrell's permission from his *Obiter Dicta*. The publishers will on application supply a list of the volumes, which if in one sense they be dear and not cheap, in another are cheap and not dear.

Messrs. MILLS and POYSER have produced a practical handbook<sup>11</sup> dealing with the administration and management of the property of lunatics, which is clearly written and conveniently arranged. Within the compass of forty pages an account is given of the circumstances under which the property of a lunatic can be dealt with and a full description of the procedure involved. The book should be of great use to the legal practitioners and receivers for whom it has been written.

## THE NEW ANATOMY BUILDING AT UNIVERSITY COLLEGE, LONDON.

BY

PROFESSOR G. ELLIOT SMITH, M.D., Litt.D.,  
F.R.C.P., F.R.S.

THE erection of the new building for the Department of Anatomy, which also provides an extension for the Department of Physiology, completes the scheme for the development of the building for the Faculty of Medical Sciences which had long been contemplated. The proposal was first definitely formulated on the initiative of Professor Starling in 1907, and on July 24th of that year the scheme was approved by the Senate of the University and "a committee was appointed to co-operate with the architect, Professor Simpson, F.R.I.B.A., in preparing plans for an Institute of Medical Sciences (including Anatomy, Physiology, and Pharmacology), with a view to the immediate erection of a portion thereof for the Department of Physiology."

The necessary funds for this portion having become available through the generosity of a number of donors, amongst whom may be mentioned Sir W. Gwynne Evans, Professor H. R. Plimmer, the late Dr. L. Mond, and Mr. Thomas Webb, the work on the new institute was begun in March, 1908. The building was completed by May 1st, 1909, and on June 18th it was formally opened by the Right Hon. R. B. (now Lord) Haldane, Secretary of State for War, in the presence of a distinguished company. From the outset the new institute, under the inspiring guidance of Professor Starling, ably seconded by Professor (now Sir William) Bayliss, attracted students and research workers from all over the world, and to such an extent that it soon became apparent that the available accommodation was not equal to the demand made upon it. The erection of the second portion of the projected Institute of Medical Sciences—namely, that to accommodate the department of pharmacology—was rendered possible by the generosity of the late Mr. Andrew Carnegie.

The pharmacology building, which adjoins the Institute of Physiology on the east side, was completed in the summer of 1912, in accordance with plans drawn up by Professor A. R. Cushman, at that time Professor of Pharmacology in the college, and was formally opened on December 4th of that year by Sir Thomas Barlow, President of the Royal College of Physicians.

A site facing Gower Street, adjoining the western end of the Institute of Physiology, was allocated for the third portion of the institute, that to accommodate the department of anatomy, hitherto most inadequately housed, partly in the north wing of the main building of the college, and partly in low buildings at the back of the Birkbeck block. Before funds were forthcoming for the completion of the scheme the great war intervened and seemed to destroy all prospect of immediate fulfilment of this aim. But the college did not abandon hope, for when a new Professor of Anatomy was appointed in 1919 reference was made in the terms of his appointment to the intention of the college to provide a new building for anatomy as soon as the means for doing so became available. Nevertheless, not even the most sanguine member of the college could have anticipated that this confidence was destined to be justified so soon as it was.

If the war seemed to have destroyed any chance of the immediate fulfilment of our plans, it was also responsible for bringing us into closer and more sympathetic relations with the academic institutions and medical men of the United States of America. The Rockefeller Foundation was eager to give some striking expression of American friendship to the British Empire, and was also anxious to enlist the help of British medicine in its great schemes for "the promotion of the well-being of mankind throughout the world."

The Rockefeller Foundation has long recognized how much the well-being of mankind is dependent on the advancement of medical knowledge and on the training of men who can spread the benefits of this knowledge among their fellow creatures, and to this end has spent large sums, not only in the United States, but also in South America and in China, for the establishment of medical schools in which research and the education of medical men should go hand in hand.

At the end of 1919 two representatives of the Rockefeller Foundation—Dr. Wickliffe Rose, general director of the International Health Board, and Dr. Richard M. Pearce, adviser in

medical education to the Foundation—came to Europe to inquire into the methods, problems, and needs of medical education in this country and on the Continent. While in London they were informed of the new developments in medical education which had taken place in this city under the stimulus and with the financial help of the Board of Education. This development consisted in the establishment at several of the medical schools of clinical "units" in medicine, surgery, and gynaecology, which were staffed by whole-time teachers, so that these subjects could be treated like the cognate scientific subjects, the professor being able to devote all his working hours to teaching and research without being obliged to undertake private practice. This innovation especially excited the interest of the representatives of the Rockefeller Foundation since the Foundation had already played a large part in the encouragement and endowment of this system of medical education in America.

The essential feature in this system is the close co-operation between all departments concerned in the medical curriculum. It is recognized that medicine and surgery cannot advance except in association with and assisted by the other departments hitherto regarded as more purely scientific—in particular, pathology, anatomy, physiology, and biochemistry.

At University College Drs. Rose and Pearce found a hospital which had been founded for the express purpose of medical education. They found also active and well equipped institutes for the study of some branches of medical science and definite plans for the completion of a whole scheme of medical education as soon as the necessary funds were available. Thus in the college there was fair provision for physiology, pharmacology, and biochemistry, but no proper facilities for teaching and research in anatomy, embryology, and histology. In the clinical subjects of the curriculum, while medicine and surgery were represented by whole-time professors at University College Hospital Medical School, there was a lack of beds devoted entirely to the work of these units, and the accommodation for research into the chemistry of disease was deficient; there was no adequate provision for scientific investigation and teaching of midwifery and the diseases of women. Plans for the remedying of these gaps in the scheme were ready; the only thing necessary for the realization of the scheme was money. The representatives of the Rockefeller Foundation were impressed with the possibilities of the scheme for the creation of a complete and scientifically equipped school of medicine which had been worked out by the college and hospital medical school and reported favourably thereon to the Rockefeller Foundation. As a result of their report the Foundation decided not only to place at the disposal of University College sufficient funds for the realization of the scheme that was formulated in 1907, but also to provide the additional endowment required to maintain the increase in staff which the scheme entailed. At the same time the Rockefeller Foundation made an even larger gift to University College Hospital Medical School for the promotion of the work of the clinical units.

It is singularly appropriate that the attempt to institute radical reforms in the teaching of anatomy and in the provision of facilities for real research should be made in University College. Paradoxical as it may appear, the reforming zeal of Professor Sharpey at this college twenty years ago had as one of its ultimate results the coupling of anatomical effort in England, and it is proper that the college which created a physiology so vigorous as to take itself the more vital and progressive parts of anatomy should be the institution to right this ancient wrong by restoring to anatomy the opportunities for teaching and research in histology and practical embryology, and for the experimental study of the factors that influence growth and development.

The structure of the nervous system, its development, history and the connexions displayed by degeneration and experiment, are all subjects which should be studied as one connected whole in the department of anatomy; and if the complexities of the nervous system are to have any real functional significance of the arrangements must be described and the effects of damage to the nervous system must be studied not with any pretence of teaching the student clinical medicine but in order to give him some satisfying explanation of a complex and otherwise unintelligible mechanism. It is necessary, then, in any properly equipped institute of anatomy, to provide a neurological department fully equipped

with sets of slides of adult human and embryonic material and of the brains of other vertebrates, and with laboratories for the experimental study of the results of degeneration.

It is an essential part of the work of a department of anatomy that it should carry on experimental investigations of the factors which influence growth and development and of the causation of anomalies and monstrosities. Such researches have led to results of very great importance from the insight they afford into the underlying principles of development as well as in explaining the causation of pathological conditions. The equipment of laboratories for such experimental work is therefore a necessary part of the scheme.

The knowledge of the structure of the living body that can be acquired by the use of the  $x$  rays is becoming increasingly important in the study of anatomy. At present a student is called upon to interpret radiograms long after he has left the department of anatomy, and when his practical familiarity with the arrangement of the structures he is endeavouring to disentangle has grown dim. Obviously the proper time to acquire an understanding of  $x$ -ray appearances is when the student is actually studying the things of which the  $x$  rays cast shadows. But such studies also teach him his anatomy, and are a valuable means of instruction. Moreover, the equipment of a department of radiology opens up a most promising field of anatomical research, which is bound to become increasingly fruitful year by year as the technique of radiography is improved.

The completion of the building for the three closely allied sciences of anatomy, physiology, and pharmacology represents far more than the mere provision of accommodation and equipment for teaching and research in anatomy and of an extension of the physiological laboratories. It is the expression of a far-reaching scheme of co-operation—involving on the one hand the closer correlation of teaching and research in anatomy, physiology, and pharmacology, and on the other the linking up of the work done in the Faculty of Medical Sciences in the college with that done in the Medical School of University College Hospital. Moreover, the new building is a permanent symbol of the bond of sympathy that unites us in a common aim with the medical schools of America and with the Rockefeller Foundation, our great benefactor.

By housing the departments of anatomy (with histology and embryology), physiology, biochemistry, and pharmacology in one institute, with a library and staff room in common, the way has been prepared for a closer co-operation between teaching and research in these subjects than has been possible hitherto. The new anatomy building is linked by means of a tunnel passing under Gower Street with the medical school of University College Hospital, and it is anticipated that this physical avenue of communication will facilitate a freer intercourse between the workers upon the two sides of Gower Street, to their mutual benefit.

The extension of the department of physiology affords ample provision for teaching and research in experimental physiology, and makes it possible for Professor Starling to remain in the college as Foulerton Research Professor of the Royal Society, even though he relinquishes the Jodrell Chair of Physiology and the directorship of the institute which he created.

The Rockefeller endowment has made it possible not only to create a University Chair of Biochemistry but also to increase the accommodation allotted to this subject. It has thus become feasible to effect a reorganization in the teaching of this new and important branch of chemistry, and to provide for the needs, not only of the students of medicine, but also for the training of biochemists, for whom there is a constant demand in research and industry. For these a definite curriculum has been devised based on the fact that a biochemist should be above all a well trained chemist, as well as possessing a scientific knowledge of general biology or of biological subjects. On this foundation is built one or two years' work in the biochemistry department, selected students being given facilities to carry out original investigations during the latter part of the course.

As announced last week, their Majesties the King and Queen have graciously consented to visit the buildings on May 31st, when the foundation stones of the new obstetric block and of the nurses' home connected with University College Hospital will be laid and the new Institute of Anatomy formally opened.

## RECENT ADVANCES IN MEDICAL EDUCATION IN ENGLAND.

SECOND MEMORANDUM BY SIR GEORGE NEWMAN.

[FIRST NOTICE.]

IN 1918 the Board of Education published a Memorandum entitled "Some Notes on Medical Education in England," by Sir George Newman, K.C.B., M.D., Chief Medical Officer of the Board. He is now also Chief Medical Officer of the Ministry of Health, and it is that Ministry which has issued a new Memorandum.<sup>1</sup> It is a document of much importance, and no phase of education in medicine seems to have been omitted. We propose this week to begin an account of its scope and contents, leaving comment to a subsequent occasion.

The Memorandum follows broadly the subjects of the medical curriculum in the sequence in which they are ordinarily taken at the schools, but it has a brief historical introduction dealing especially with the work of the General Medical Council in its developments from 1858 to 1922, and with the institution in 1908 of Treasury grants to universities and medical schools, through the Board of Education in England, and directly by Parliament for Scotland and Ireland. The seven points to which special attention is given in assessing grants are: (1) the number of students, (2) the content and scope of each subject taught, (3) the educational staff, (4) equipment and clinical facilities, (5) the standard and character of teaching, (6) the correlation of subjects and interrelation of laboratory and clinical work, and (7) research work. A University Grants Committee was appointed to take the place of the Board of Education as from 1919, and grants are paid to practically all the fifteen universities in Great Britain.

In dealing with the preliminary sciences the opinion is expressed that chemistry, physics, and biology are fundamental. The centre of knowledge is for ever shifting and "we are in need of a closer association between physics and chemistry on the one hand and biology and medicine on the other." The author expounds the General Medical Council's policy, which is that the elements of these subjects should be taught at the secondary or public schools to the standard of the preliminary examination. Their applications to medicine are to be taught during the medical curriculum, which is so far lightened. Many excellent courses of this nature are now, it is said, established under the regulations, but Sir George Newman urges: "In such advanced courses one primary consideration should be paramount—namely, that proper provision should be made for the concurrent study of English language, literature, and history." More than 250 secondary schools now give advanced courses, but not nearly so many in biology as in chemistry and physics. Six examples of the courses of instruction are quoted from reports by H.M. inspectors. The medical schools will have to supplement any insufficiencies of the secondary schools. Biology is regarded as of special importance—"it is the basis of sociology." The author holds that zoology and botany must continue to be taught separately. It is urged, again, that the teaching of the principles of chemistry should not be allowed to suffer by giving the student too much inorganic chemistry. Finally, as to the preliminary sciences: "When the student enters upon the professional part of his course these subjects must be deeply integrated into physiology, pharmacology, and pathology, and practically applied in his clinical studies."

### Anatomy.

"Anatomy is the foundation of the Science and Art of Medicine": so begins the chapter on that subject. But it became a restricted subject "neither biological in setting nor physiological in purpose." The student was overburdened with detail and could pass examinations only by "cramming." The anatomy was that of the dead and not of the living body—not like that of the Greeks, who learned from athletes in action; it was divorced alike from biology and clinical study. But there was a renaissance in both respects; Harvey was a biologist and John Hunter and the Monroes were surgeons or teachers of surgery. The purpose and meaning of anatomy can only be learned at the same time as its structure.

<sup>1</sup> *Recent Advances in Medical Education in England*. A Memorandum addressed to the Minister of Health by Sir George Newman, K.C.B., M.D., Hon. D.C.L., F.R.C.P., Chief Medical Officer of the Ministry of Health and of the Board of Education, Crown Nominee to the General Medical Council. London: H.M. Stationery Office, Imperial House, King's-way, W.C.2. 1923. 1s. 3d. net.

Anatomy has come back into its inheritance through orthopaedics. Teaching and examination must have regard to the needs of the practitioner, and the General Medical Council recommends that the final examination should include questions on the applications of anatomy and physiology to practical medicine. The knowledge must be accurate and the student must be encouraged to take broad views but not vague views.

#### *Physiology.*

In dealing with the teaching of physiology, which has undergone such enormous expansion, it is pointed out that there are three desiderata: a knowledge of the normal action of the healthy body and its variations; a knowledge of disturbing factors and how to investigate them; and the application of the principles to medicine. Lecturing, which has been overdone, has now been much reduced, and the student needs less if he has been well grounded in biology, physics, and chemistry. From animal physiology in general the student must pass to mammalian physiology and then to human physiology in particular. An important aspect of the subject, emphasized by war experience but essential also for civil industry, is the total efficiency and vital capacity of man, his ability to resist and recover from strain. The student should learn how wide are variations within the normal bodily functions, and to distinguish variation from disease. The science is being taught more adequately than formerly and the teaching is being continued throughout the curriculum—"students are learning to think of disease as disordered physiology." A Scottish branch subcommittee of the General Medical Council has suggested the lines which should be followed in bringing physiology to the student on medicine in respect of circulation, the nervous system, metabolism, the endocrine organs, reproduction and development, and the physiology of childhood. In some schools the student in his second year is being brought to the hospital to study cases illustrative of physiological principles or methods. "An all-round equipment in physiology is perhaps the greatest single need of the medical student." The teaching must be practical, there must be no watertight compartments, no divorce of physiology from pathology and clinical medicine and surgery, and the spirit of research should be cultivated by the personal work and observation of every student.

#### *Pharmacology and Therapeutics.*

It is good for all concerned that every teacher be filled with the importance of his own subject, and the next chapter of the Memorandum begins with a quotation from Professor W. E. Dixon of Cambridge, who writes that "To state that the future of medicine lies in pharmacology may sound fanciful, but it is certain that the most hopeful of all signs of the progress of Medicine of to-day is to be found in the progress of the science of treatment." In recent years the orientation of therapeutics has been changed, first by experimental observations on the active principles of drugs and their effect on animals; secondly, by speculations relating to the chemical structure of the molecule, and the processes of absorption, surface tension and solution; thirdly, by the discovery of the importance of internal secretions—drugs within the economy and extractable for use; and, lastly, by new knowledge of the defensive substances within the body and by the revolutionary developments in serology and immunology. In Great Britain synthetic chemistry has not been widely developed and we have had to rely on Continental laboratories for new anaesthetics, hypnotics (which, it may be interpolated, bring with them their own dangers), vaso-dilators, antipyretics, diuretics, synthetic purgatives, etc. As a remedy the establishment in this country of an Institute of Experimental Therapeutics is urged, to comprise all branches of pharmacology, chemical, experimental, and clinical. Pharmacology "must be explored in conjunction with physiology, with pathology, and above all with therapeutics." The Memorandum after this admonition proceeds to discuss seven aspects of the subject: (1) Vaccines and serology, (2) organotherapy, (3) heliotherapy, (4) electrotherapeutics and radium, (5) mechano-therapeutics, (6) anaesthetics, and (7) psychotherapy. There are also some concluding observations on practical methods of teaching.

Though the percentage of successful vaccinations against small-pox is under the present system 99.4 in the hands of Public Vaccinators, yet Sir George Newman holds that the training of the medical student has become perfunctory and that steps should be taken for its amendment. Knowledge of acquired immunity in general has resulted in a new and powerful means both of diagnosis and therapeutics in respect of typhoid, food poisoning, dysentery, pneumonia, diphtheria,

syphilis, tuberculosis, and other bacterial infections. Another result is the preparation of vaccines and antitoxins for prophylaxis and treatment, whether the means be living or dead cultures, and whether the vaccines be polyvalent or autogenous. Neither the practitioner nor the student can be an expert in such matters, but there should be elementary instruction in the principles of immunity, the methods of preparation of vaccines and serums, the diseases for which they are available, the principles for selection of stock, the time, method, site and doses, the action and reaction, ill effects and risks, and instruction also in the convincing evidence of their value in small-pox, rabies, diphtheria, and typhoid fevers.

Organotherapy is represented by the value of thyroid extract, adrenaline and pituitrin, as means of treatment based upon the principle of compensating defect by extracts from internal secretions. Heliotherapy should also be taught and illustrated by its success in the tuberculosis of children, and generally in the open-air life. Sir George Newman supports the recommendation of the General Medical Council that radiology should be systematically taught, including the differential reading of radiograms. Under mechano-therapeutics come massage and remedial exercises, of which the methods and value should be known to practitioners, though the work needs particular training and experience. Swedish exercises at schools have become universal since the school medical service began. In anaesthetics the General Medical Council recommends that every student have a course of instruction, including experience of their administration in at least ten cases. As to psychotherapy, Sir George Newman writes aptly that "some forms of treatment of mental disease have overflowed their boundaries and invaded the realm of internal medicine." In nervous disorders "its methods are analysis, suggestion, persuasion, or reinstatement of disordered function," but it is not yet a science, and much depends on the "personality" of patient and physician. It is important, however, that the student receive instruction in elementary psychology, perhaps as part of physiology.

The consideration of practical methods of teaching, both in pharmacology or the scientific study of drugs, and in therapeutics or the art of treatment, is prefaced by the observation that practical pharmacy has disappeared from the scheme of training. In Edinburgh there are now two whole time professors, one for either subject, the therapeutics professor being also professor of clinical medicine; attached to the wards is a therapeutic laboratory. At other schools—Sheffield, Oxford, Cambridge, and Aberdeen—there are also special arrangements.

#### *Pathology and Elementary Bacteriology.*

Pathology, it is observed, has developed from a mere means of throwing light on treatment to be an independent science with ramifications into all branches of medicine and surgery, so that practical medicine has become diagnosis, pathology, and treatment, and practical surgery, diagnosis, pathology, and application of the mechanical arts; "the integration has been so intimate that the science has become woven into the warp and woof of the whole texture of medical practice." It began as morbid anatomy, next came morbid histology, then bacteriology, and now there has emerged the pathological physiologist, who studies "disease in the living cell rather than the dead," function rather than structure, to be learned in the wards as well as in the post-mortem room. Stated otherwise it is "the science of morbid processes." It should include elementary bacteriology, morbid anatomy and histology, general and special pathology and their chemistry, experimental pathology, and clinical pathology, all in a setting of comparative pathology. The subject should be spread over two or three years of the curriculum, beginning with elementary bacteriology and pathological chemistry. The professor should be pathologist to the hospital of the medical school, and the hospital should have attached to it an institute to bring together all branches of pathological work; each student should collect material and carry out its examination, should also do several autopsies and compare the results with the clinical phenomena. Conference of all concerned with a case would likewise be held. Each school should have an organization for pathology complete in accommodation and equipment, and there should be co-operation between physiologist, pathologist, bacteriologist and clinician. For absolute completeness a school of comparative pathology—vegetable, animal, and human—is needed, and such a school should be connected with hospital wards and laboratories.

(To be continued.)

## COLLOIDAL PREPARATIONS.

## THE EXAMINATION OF COLLOIDAL SOLUTIONS.

BY

SIR WILLIAM J. POPE, K.B.E., F.R.S., D.Sc., LL.D.,  
PROFESSOR OF CHEMISTRY, UNIVERSITY OF CAMBRIDGE.

A RECENT paper by Professor A. J. Clark (BRITISH MEDICAL JOURNAL, 1923, i, p. 273) contains a discussion of the customary methods for distinguishing colloidal solutions from those of crystalloids and details the results of the examination of a number of colloidal preparations found in commerce. It is stated that the work was carried out at the expense of the British Medical Association, and it may therefore be presumed to carry with it the authority and approbation of this important body; this latter circumstance makes it particularly unfortunate that many, if not most, of the experimental results recorded in the paper are erroneous and misleading, and that, in consequence, the conclusions drawn are unjustified.

The refutation of an error is always a more lengthy process than is its original statement; without discussing detail by detail the sequence of mistakes made in the paper under discussion it will suffice, and the interests of brevity will be served, if Professor Clark's conclusions concerning but one from among the many preparations with which he has dealt are shown to be unfounded.

The solution known as "colloidal ferrum Crookes" contains 0.05 per cent. of iron as a colloidal ferric compound, with about 0.5 per cent. of gelatin and about 3.5 per cent. of glucose, as may be ascertained by any competent analyst; it passes through filter paper without leaving a precipitate, and is faintly alkaline in reaction owing to the presence of a small proportion of sodium hydroxide. Presumably everyone is aware that ferric salts are precipitated by sodium hydroxide unless retained in colloidal solution by some protective substance. The fact that sugars retain ferric iron in colloidal solution was recorded by Thomas Graham in his famous first paper on colloids (*Philosophical Transactions of the Royal Society*, 1861, 151, 183), and has been the subject of much later experimental study. The simple and direct proof that such solutions contain the iron in the form of colloidally suspended particles, which can be seen in the ultramicroscope, is so complete that the colloidal character of these preparations has never before been impugned.

But Professor Clark disregards the effect of the gelatin and the glucose and does not note the alkalinity of the solution, the factors which directly prove the colloidal condition of the iron in the preparation. He observes that the ferric compound passes through a collodion filter and thence concludes that the iron cannot be in a colloidal condition, oblivious of the fact that colloidal filters are in common use for separating fine and coarse colloidal suspensions, the finer readily traversing the filter.

Professor Clark remarks that extravagant statements concerning colloidal preparations have been often recorded, and that much of the "scientific" literature on the subject is uncritical; this is regrettably true so far as the medical literature is concerned, and makes it the more desirable that the British Medical Association and Professor Clark should discountenance the methods of the past and confine themselves to the publication of properly ascertained facts with their logical conclusions. The dangers of not doing so have been eloquently depicted by Dr. H. H. Dale (*Journ. Soc. Chem. Ind.*, 1920, 39, 211 R).

## OBSERVATIONS ON THE ABOVE ARTICLE.

BY

A. J. CLARK, M.D., F.R.C.P.,  
PROFESSOR OF PHARMACOLOGY, UNIVERSITY COLLEGE, LONDON.

I HAVE read the above article by Sir William Pope with surprise. He states of my paper "that many, if not most, of the experimental results recorded in the paper are erroneous and misleading." He does not, however, produce any evidence to show that a single experimental fact stated in my paper is incorrect. It is, of course, contrary to every tradition of scientific controversy to make a sweeping charge like this

without establishing it to the hilt. This is, however, a minor question.

Sir William Pope concentrates his attention on my findings as regards collosol ferrum, and says:

"The solution known as 'colloidal ferrum Crookes' contains 0.05 per cent. of iron as a colloidal ferric compound, with about 0.5 per cent. of gelatin and about 3.5 per cent. of glucose, as may be ascertained by any competent analyst; it passes through filter paper without leaving a precipitate, and is faintly alkaline in reaction owing to the presence of a small proportion of sodium hydroxide. . . . But Professor Clark disregards the effect of the gelatin and the glucose and does not note the alkalinity of the solution, the factors which directly prove the colloidal condition of the iron in the preparation." (The italics are mine.)

Messrs. Crookes, as far as I am aware, have no preparation called "colloidal ferrum Crookes." The substance I investigated was "collosol ferrum Crookes," and I presume that Sir William Pope is referring to this, otherwise his remarks are pointless.

The two statements italicized in the above quotation relate to matters of elementary chemistry. I cannot confirm either of them.

During the past year I have tested six separate bottles of collosol ferrum Crookes bought over a period from January, 1922, until April, 1923; some were bought from retail and some from wholesale chemists. In every instance the solution was acid. To-day (April 19th) I opened two new bottles of collosol ferrum; one bottle had been recently obtained from a wholesale chemist and the other came to-day from Messrs. Crookes's establishment in Chenies Street; the contents of both bottles were acid: the acidity corresponded approximately to N/200 and N/500 acid respectively. Having made these observations and measured the degree of acidity I cannot quarrel with Sir William Pope's statement that I do "not note the alkalinity of the solution."

Collosol ferrum gives all the reactions characteristic of a dilute solution of a ferrous salt—namely, a deep blue colour with potassium ferricyanide which develops immediately, a paler blue colour with potassium ferrocyanide which develops slowly, and no colour with ammonium sulphocyanide. These reactions are totally different from those given either by an ordinary solution of a ferric salt or by a solution of colloidal iron.

As regards precipitate, five out of the six specimens which I have examined left a heavy precipitate when filtered through a filter paper. One of the two bottles examined to-day yields 0.08 per cent. of precipitate on filtration; the other bottle, obtained fresh to-day from Messrs. Crookes, gives no precipitate.

As regards colloidal condition, I showed in my paper that the iron in collosol ferrum, when tested by dialysis, ultrafiltration, or diffusion, behaved exactly as if in true solution. Sir William Pope argues that the iron in "colloidal ferrum" must be colloidal because it is in the ferric state and the solution is alkaline. The iron, however, is in the ferrous state and the solution is acid.

So far as I understand Sir William Pope, the only other evidence he adduces is that the solution shows colloidal particles on ultramicroscopic examination and contains gelatin and sugar. If my interpretation of Sir William Pope's statement be correct, I will leave it to chemists with experience of colloidal chemistry to say what they think of the argument that iron in a solution must be colloidal if the solution contains particles visible under the ultramicroscope, and also contains gelatin and sugar.

Sir William Pope, however, really bases his argument on the alkaline reaction of the fluid. When a person in his position bases an important argument on an elementary fact like this, and one finds that the statement is wholly incorrect as regards six separate samples of the substance under investigation, discussion becomes very difficult.

In the above circumstances it seems unnecessary to notice Sir William Pope's unkind remarks about my methods of research. In my paper I dealt with collosol ferrum Crookes as sold to the medical profession. Sir William Pope has publicly ridiculed me for failing to notice that it is alkaline. I say that it is acid, and that anyone who is in doubt can determine this point for himself with a piece of litmus paper.

## British Medical Journal.

SATURDAY, APRIL 28TH, 1923.

## PITUITARY SECRETION.

ALTHOUGH extracts of the posterior lobe of the pituitary gland are now widely used in obstetrics and in surgery, knowledge of the functions of this gland is still very fragmentary. This is in large measure due to the extreme difficulty of removing the posterior lobe of the pituitary without injuring the anterior lobe or the adjacent portions of the brain. The known actions of pituitary extract are extremely diverse, and this is understandable since the gland is known to yield several active principles. Abel and Rouiller<sup>1</sup> showed that at least two substances were present, one which raised and another which depressed blood pressure. Dudley,<sup>2</sup> in a recent paper, has shown that the substance which raises blood pressure is probably distinct from the substance which causes constriction of the uterus.

Very little evidence has been brought forward to indicate the nature of the relation between the pituitary gland and the genital organs, but Professor W. E. Dixon, in a recent paper,<sup>3</sup> has thrown some light on this question. He has made a series of experiments which lead him to conclude, first that secretion of the pituitary gland is delivered into the cerebro-spinal fluid, and secondly, that this process of secretion can be stimulated by injection into the circulation of either pituitary extract or of ovarian extract. It seems clear, he says, "that ovarian conditions determine the secretion of the pituitary and thus react indirectly on the uterine tonus. Pituitrin is very largely employed in medicine to contract the uterus: its employment would seem to be so far rational that it is the drug manufactured by the body for this specific purpose."

The facts established concerning the functions of the posterior lobe of the pituitary indicate that they are curiously scattered. The internal secretion of this gland appears to be essential to the normal function of the kidney, for injury to the lobe is often associated with diabetes insipidus mellitus, and in a large proportion of cases of this disease the excessive urinary secretion can be inhibited by the administration of pituitary extract. Furthermore, Starling and Verney have recently shown that the isolated kidney secretes very dilute urine, but that the addition of pituitary extract to the perfused blood causes an increase in the concentration of the chlorides. The pituitary is also one of the glands that control the concentration of blood sugar. Pituitary deficiency is associated with increased carbohydrate tolerance, and according to Burn<sup>4</sup> pituitary extract has a stabilizing effect on the blood sugar concentration, for on the one hand it inhibits the hyperglycaemia produced by adrenaline or by ether anaesthesia, and on the other hand it inhibits the fall of blood sugar produced by the administration of insulin.

There seems, therefore, to be a fair amount of evidence that the posterior lobe of the pituitary gland secretes *in vivo* a uterine stimulant and also a substance essential for normal urinary secretion.

This gland contains in addition substances which can raise blood pressure, which can lower blood pressure, and which affect blood sugar concentration. There is evidence that at least three separate substances are concerned in these manifold activities. We have, however, at present

no evidence as to whether these curiously diverse activities are correlated in any way; as far as our present knowledge goes, the association of the different active principles in one gland may be purely accidental.

## VETERINARY LITERATURE DURING THE EIGHTEENTH CENTURY.

THE first instalment of the history of veterinary literature by Major-General Sir Frederick Smith, late Director-General of the Army Veterinary Service, is published in the current issue of the *Veterinary Journal*. He has no difficulty in showing that during the eighteenth century the practitioners of animal medicine were in a state of deplorable ignorance of the pathology and treatment of disease. The books written during the earlier part of this period claimed to give to country gentlemen and farmers sufficient instruction to enable them to be independent of the services of the farrier and cow-leech or cattle doctor—the two classes of men engaged in veterinary practice—and usually promised secret receipts for the cure of the common distempers incident to horses and oxen. Under the titles "Every Man his own Farrier," "The Gentleman Farrier," or some variant of these, they appeared with painful regularity, the writers all dipping for information into the same well of ignorance, and copying without apology from the books of their predecessors. Whereas in the medical profession during the same period there were three classes of practitioner—the physician, the surgeon, and the apothecary; and of the first named it might be said that, though commonly more dependent on ancient tradition than modern science, he was usually a scholar—the lowest and most ignorant in the land were considered suited to follow the veterinary calling; the farrier and cow-leech were, indeed, entirely without education, and dependent as a rule on a book of "cures."

The comprehensive review of the veterinary literature during the early part of the eighteenth century provided by Sir Frederick Smith indicates the grievous suffering which must have been inflicted on animals by the "experts" of that time, of which the following may be given as examples. One author says that "suppression of urine is overcome by passing into the urethra a whale-bone, at the end of which is a knob covered with muslin; the whole is to be thrust into the bladder. If no urine follows, this is diagnostic of disease of the kidneys." The same authority recommends in the treatment of colic a remedy consisting of "four or five hundred wood-lice, dried and powdered, given in a draught." Stiff legs "are to be treated by cutting the nerves of the forelegs, which will be found in the breast." (What was removed was a piece of tendon, which was drawn out at the wound and then divided.) However, Sir Frederick Smith concludes that on the whole the veterinary pharmacopoeia was cleaner than the medical pharmacopoeia, for "in the Dispensatory of the Royal College of Physicians of this period the following are shown among the animal parts employed in medicine: fat of all animals, including that of man, bezoar, cystic calculus (human), flesh of the viper, horn of rhinoceros and unicorn, tooth of elephant and horse, slough of snake, liver of eel, biliary calculus of a jaw of pike, penis of tortoise and stag, huckle bone of hare. There is also shown, as a therapeutic agent, the moss from human skulls!"

The medical profession rendered conspicuous service to veterinary practice during the eighteenth century, both because physicians were called upon to assist the State when cattle plague appeared in this country, and because certain surgeons, from a love of animal or from an eye to business, took an active interest in the treatment of diseases of animals. It was fortunate that

<sup>1</sup> *Journ. of Pharm. and Exper. Ther.*, 20, 45, 1922.<sup>2</sup> *Ibid.*, 21, 103, 1923.<sup>3</sup> *Journ. of Physiol.*, 57, p. 128, March 21st, 1923.<sup>4</sup> *Ibid.*, 57, *Proc. Phys. Soc.*, 38, 1923.

when, in 1714, cattle plague was prevalent, Thomas Bates, F.R.S., surgeon to H.M. Household, was called upon to report upon a disease of cattle affecting dairy stock at Islington and to decide whether it was contagious. He soon convinced himself that the disease was spread not only by the affected cattle but by the attendants, and "he recommended that the entire herd should be destroyed, the owners compensated, the dead cremated, the cowhouses disinfected and left empty for three months." Thus he succeeded in eradicating cattle plague by methods almost identical with those in use to-day. Sir Frederick Smith says that the work of the physicians was marred by their nervous apprehension of loss of dignity in their profession by being engaged in the study of a disease of animals, and they nearly all apologized for debasing their profession, their only consolation being that they had exhibited a good public spirit in time of national peril. On the other hand, a number of surgeons, for whom the social sacrifice was not so serious, came forward and closely identified themselves with veterinary work, and many of them wrote books on the subject, some from actual practical knowledge, others from theoretical acquaintance or conceit. Even the surgeons were anxious about their reputations, for one of them remarks in one of his books that, as a result of "employing his pen so low as to write about horses," he has "now and then had a little dirt" thrown at him. The first school of veterinary science was opened in this country in 1791, and towards the end of the century the medical profession rendered valuable help to their veterinary colleagues through the work of John Hunter, Henry Cline, Sir Astley Cooper, and Dr. Fordyce, while from the ranks of the medical profession during the last years of the eighteenth century were recruited Bracey Clark, William Moorcroft, Delabere Blaine, and Edward Coleman, whose names will live as long as the veterinary profession exists.

## TREATMENT OF DIABETES BY INSULIN AND ITS RISKS.

WE publish this week at page 737 a general summary of the clinical experiences of workers in certain hospitals—eight in number—in England and Scotland who during the last few months have been able to treat certain selected cases of diabetes with insulin prepared under the directions of the Medical Research Council in the laboratories of the medical schools attached to each hospital; recently insulin prepared by commercial firms has also been used by these workers.

As we announced last week (p. 695), insulin is now being prepared on a commercial scale in this country, and the supply has been augmented by consignments from a firm of American manufacturers. It can now be purchased by hospitals and individual medical practitioners who will undertake to fulfil certain conditions. Insulin can only be employed with safety when its effects are tested by repeated examination of the amount of sugar in the blood, and an undertaking to make this estimation systematically is perhaps the most important condition imposed. So far, at each hospital, two or three patients suffering from severe diabetes have been selected and the effects of insulin upon them very closely studied week by week. Except in cases which have already reached the stage of coma, all the patients treated have shown admirable improvement, just as was described by the Canadian workers. The amount of sugar in the blood has fallen rapidly as a temporary result of each injection, and the utilization of fats has been favourably influenced to a very marked degree. The patients have increased steadily in weight and have experienced a sense of greater warmth and energy. Among the precautions found necessary is that

the insulin should be given in relation to the meals and be withheld during periods of abstinence from food. The untoward results of an excessive dose of insulin have been for the most part avoided owing to the care taken to test its effect on the blood and to give it in proper relation to meals. In severe cases very large doses may have to be given, and it is advised that such patients should be treated, for the present at any rate, in institutions, where the diet can be closely controlled and the blood sugar frequently determined. It is possible that in cases under this close observation a smaller dose may prove effective if carbohydrates are excluded. The very striking effect of insulin in diabetic patients who have passed into a condition of coma was observed in several instances; in one, which is recorded at length, a man admitted to hospital on the verge of diabetic coma, just conscious but with extreme air hunger, treatment with insulin was followed by such improvement in his general condition that for the next three weeks he had no glycosuria.

The efficiency of insulin in lowering the amount of sugar in the blood is so great that too large a reduction may be brought about, and a condition of collapse attended by convulsions may then ensue; it is remedied by giving glucose and causing the patient to drink large quantities of fluid; but its occurrence ought to be prevented, and this is one of the many problems which require further investigation. It has long been known that a diabetic patient subjected to an operation may suddenly pass into a condition of coma, and the experience so far obtained tends to show that insulin in this emergency has little effect. The risk is to be avoided by careful preparation of the patient before the operation; dietetic control and the administration of insulin in suitable doses being used together to free the urine from ketones and sugar.

## THE CAMBRIDGE CHAIR OF ANIMAL PATHOLOGY.

THE University of Cambridge is about to make a new departure of considerable interest and importance. As announced recently in our columns, it has accepted an offer made by the Ministry of Agriculture and Fisheries of a capital sum of £30,000 to found a Professorship of Animal Pathology. The Senate has approved regulations for the professorship which fix the stipend at £1,200 per annum, and define the duties of the office as the advancement of the knowledge of the diseases of animals by teaching and research. A board of electors will shortly be nominated, and it is anticipated that the first appointment will be made during the present term, which ends about the middle of June. The professor will be connected with the Special Board for Agriculture and Forestry, and will have his headquarters in an extension of the School of Agriculture, which practically joins the new biochemical laboratory which is being built and presented to the University for Professor Hopkins by Sir William Dunn's Trustees. Professor Langley's laboratory, the Molteno Institute of Parasitology under Professor Nattall, and the low temperature research station under Mr. W. B. Hardy, are all within a stone's throw, and the Medical School is only just across Downing Street. The professor is to hold office in the first case for five years, at the end of which period he will be eligible for reappointment. His first duty will be to prepare plans for his headquarters laboratory at the School of Agriculture; for a branch laboratory, paddocks, animal houses, etc., at the field laboratories; and for staff and for equipment. For these purposes the Ministry of Agriculture has intimated that it will consider estimates up to about £70,000 for the period ending March 31st, 1927. After this date the maintenance of the research institute, of which the professor will be director, must depend either on the provision of further funds by Parliament or on private benefactions. In view of the value of the live-stock industry to the country, the collapse of the

institute in 1927 for lack of funds cannot be contemplated, provided, of course, that the professor and his staff show signs of making good. Although the regulations mention teaching among the professor's duties, it is anticipated that, for the present at any rate, his whole time will be devoted to research, which it is hoped will not be confined to purely laboratory studies. The funds available for the next four years will make it possible to include in the equipment a travelling laboratory for the study of outbreaks of disease in any district where they may occur. A motor ambulance and a compensation fund could also be provided so that certain animals could be transferred to Cambridge for more intensive study. It is thought that the application of such methods may throw light on many disorders of sheep and swine. As the market price of such animals is comparatively small they seldom repay individual attention by the veterinary practitioner. They would, however, amply repay preventive measures founded on accurate study of the outbreaks of diseases to which they are liable. Although the professor will be most directly connected with the School of Agriculture, the financial control of his institute being in the hands of the Special Board for Agriculture and Forestry, Sir Clifford Allbutt's well known advocacy of the joint study of human and animal disease will ensure for him the hearty co operation of the Medical School.

#### THE CALCUTTA SCHOOL OF TROPICAL MEDICINE AND HYGIENE.

This institution was formally opened in February, 1922, although the first classes and research work were commenced about three months earlier; it was not until June, 1922, that the special hospital with over a hundred beds for tropical diseases was in full working order. In the first annual report, that for 1922, the Director, Lieut.-Colonel W. D. Megaw, I.M.S., in addition to giving an interesting account of the post-graduate teaching and hospital work, summarizes in fifty large printed pages the researches of the fifteen professors and whole-time research workers in charge of different sections of the laboratories; he gives a list containing twenty-five published papers and twenty-five submitted for publication: a truly remarkable record for the first year's work. After paying a tribute to the founder, Sir Leonard Rogers, in which he says that the institution is "the most remarkable legacy which has ever been bequeathed by a European to India," the teaching work is described: a six months' course is held in the cold weather months for the school diploma; outside examiners are appointed, and only 19 out of 28 candidates were passed, the standard being very high; a three months' course for a school certificate begins on July 15th, but there were 80 applicants, the numbers in each class limited to 50, including the D.P.H. candidates, who have a nine months' course, with field demonstrations and additional practical teaching in the public health laboratory of Bengal within the school buildings. The lectures are illustrated by numerous lantern slides, epidiascope projections, and cinematograph films, while the clinical material is abundant; over 600 cases of kala-azar, for example, were treated in the hospital and out-patient department in one year. Every patient admitted is investigated by the bacteriological, protozoological, helminthological, serological, and other laboratory departments, the notes being indexed by a whole-time registrar, so that any point under investigation can easily be analysed at short notice. The Calcutta Medical College museum contains some 6,000 specimens and several hundred coloured drawings; the numbers are being added to daily by the whole-time artists and photographers of the college and the new school, but it is already a unique collection of tropical specimens, and in addition a pictorial collection on the lines of the Wellcome Museum of Tropical Diseases is being rapidly arranged on the ample wall space of the entrance hall, stairs, and landings. Altogether the tropical school affords unequalled advantages for a highly practical post-graduate teaching in tropical medicine and hygiene of the most complete kind. The medical staff now numbers thirty-six, including eight

whole-time professors and three part-time lecturers, three whole-time assistant professors, four medical officers of the hospital, seven additional whole-time research workers, three of whom are Indian research scholars in charge of investigations, and five assistant research workers; the heads of the seven additional research laboratories over and above the staff of professors are engaged in investigations on kala-azar, ankylostomiasis, the dysenteries, leprosy, filariasis, beri-beri, and diabetes respectively; all of them also teach in the school in their specialties, while distinguished outside medical men are invited to lecture from time to time. Additional professors of helminthology and biochemistry will, it is expected, be appointed shortly, and money is already in the hands of the Endowment Fund for the construction and equipment of a new leprosy institute opposite the school; this fund, which also finances the seven research laboratories just mentioned, had an income of £8,000 last year and a balance at the end of the year, including investments, of £45,000; almost the whole has been raised by public subscription—a fine testimony to the esteem in which the institution is held in India. A particularly valuable feature of the research work is the cordial co-operation among the staff; a large proportion of the papers are the joint work of two or more departments showing team work at its best. This happy result is mainly due to a system suggested by the founder of having monthly meetings of all the investigators, at which each reports on his previous month's work and his future plans; any difficulties encountered there receive the attention of the whole staff for their elucidation, so that the administrative head can say that he regards himself rather as a "President" than as a "Director" of the school. It is impossible to read this report without realizing how much the splendid start the school has made is due to the wise and tactful administration of Colonel Megaw, backed up, as he himself points out, by a very able and enthusiastic staff. He makes special acknowledgement of his indebtedness to Major Knowles for his splendid work in completing the organization of the laboratories and hospital after Colonel Rogers went home on sick leave shortly before coming under the age retirement rule. Sir Leonard Rogers has every reason to be proud of the good work of his successors, in the selection of whom he was particularly fortunate. How far the work of the Calcutta School will be crippled, if the proposals of the Retrenchment Committee to scrap no less than twelve out of about thirty members of the bacteriological department and to reduce very seriously the medical research funds are carried out, it is impossible at present to judge.

#### CONGRESS OF THE HISTORY OF SCIENCE.

The fifth International Congress of the History of Science met in Brussels on April 8th, and the official opening took place on Monday afternoon, in the presence of the King of the Belgians, in the Hall of the Palais des Académies. There was a large attendance of delegates and members. The History of Medicine formed a subsection, located at the Hôtel Ravenstein. The attendance of members interested in the subject was disappointing, but some interesting papers were read. Among these may be mentioned that by Dr. Wickersheimer (Strasbourg) on "The accusations of poisoning directed against Jews and lepers in the fourteenth century, and their relation to the plague epidemics." At the time of the Black Death the Jews were accused of spreading the disease by poisoning the water in the wells. This statement is to be found in many history books and in 1348 such an accusation was said to have cost thousands of Jews and lepers their lives. Another interesting paper was communicated by Dr. van Scherrenberg (Antwerp) on "Itinerant oculists in the Belgian provinces in the seventeenth and eighteenth centuries." He reminded his hearers that in the Middle Ages ophthalmia was the chosen field of the ignorant practitioner. The study of the eye from an anatomical and physiological point of view had developed to an appreciable degree during the seventeenth

and eighteenth centuries, but its practical use as applied to the treatment of patients had not yet made itself felt. It dawned on the itinerant surgeons of the day that human sufferings, judiciously exploited, might become a source of revenue to them. Printing, which had proved so powerful an agent in the dissemination of new theories, would provide them with an easy means of introducing themselves favourably to the uneducated masses. This propaganda was first carried on by means of short tracts in which the merits of these charlatans were set out in lyrical terms, and at the close of the seventeenth century the first medical advertisements appeared. In the year 1686 an anonymous "Venetian" extolled in the *Courrier véritable des Pays-Bas* the virtues of his balsam for curing fractures. These first advertisers professed to cure cataract, deafness, and the stone, to operate for hernia, to sell wonderful cures for all and every ill, and to supply false teeth and artificial eyes. A paper was read by M. Oscar van Schoor (Antwerp) on "The history of the pill." He said that the pill was one of the oldest pharmaceutical preparations, being mentioned by Hippocrates, Galen, Pliny, and Celsus. The old authors gave little detail with regard to the method of making up the pillular mass and its division into doses. Towards the end of the seventeenth century references were made to the "signet," an instrument for dividing the pillular mass into equal parts; this was the precursor of the modern pill-machine, first described by "Baumé" in his *Éléments de Pharmacie*. The method of gilding or silvering the pills, or by sprinkling them with fragrant powders to help in their preservation, was common in the fifteenth century. In ancient pharmacy, the pills were kept in a mass and were only divided up into doses as required. M. Sevilla of Paris contributed a paper on "Some aspects of Greek veterinary medicine and the posology of opium and a few active 'simples' inscribed in the therapy of horses affected by pulmonary diseases." He made a critical analysis of the therapeutical formulæ written by various Greek veterinary surgeons of the later period in Greek history, on the pulmonary diseases of the horse. He dealt in succession with the internal use of opium and henbane, asafoetida, gum ammoniacum, turpentine resin, sulphur, and sulphuret of arsenic in the treatment of horses suffering from bronchitis, pneumonia, pulmonary emphysema, and asthma. These agents were known even at an earlier period and were used by those who specialized in the treatment of sick horses. Professor Marc Bloch (Strasbourg) contributed a paper on "A confusion of beliefs: Concerning the kings of France, Saint Marcoul, and seventh sons as healers of scrofula." He said that three kinds of miracle-workers were believed to have the power of curing scrofula in France in the old days: kings, one saint (St. Marcoul), and seventh sons—that is, the youngest of seven boys, without girls intervening. Each of these powers, or supposed powers, had its origin in a different belief. The people soon established a common centre for these thaumaturgical powers in spite of their widely different origin. In the fourteenth century the kings of France were accustomed after their coronation to go and perform their devotions at the principal shrine of St. Marcoul, situated at the priory of Corbeny in the diocese of Laon, and they came gradually to consider this saint as the "intercessor" to whom they owed their supernatural gift. Thus saint and king became almost inseparable in iconography; and as to seventh sons, from the seventeenth century at any rate, a mysterious relationship was supposed to exist between them and the royal dynasty. These superstitions existed well into the middle of the nineteenth century.

#### ACADEMIC DRESS IN SCOTLAND.

An interesting question has been raised in a report issued by the Aberdeen University General Council's Business Committee on the subject of academic gowns and hoods. The matter at present affects the M.A. hoods of Aberdeen and Edinburgh Universities, but it has an indirect bearing upon

the academic insignia of all British degrees. It appears that the governors of Gordon's Technical College, Aberdeen, proposed that holders of a diploma of the School of Art in that city should be granted the privilege of wearing a black gown with hood of black lined with white silk (the M.A. hood of Aberdeen and Edinburgh, and incidentally also of Cambridge). A subcommittee appointed by the Aberdeen University Council has gone fully into the matter and consulted the Universities of Oxford, Cambridge, and London as to any precedent for such assumption of academic dress by non-academic bodies. It appears that certain institutions, which are not universities, are entitled by charter or otherwise to adopt academic dress—for example, the College of Organists and the Royal College of Science. It is stated that the origin of academic robes is to be found in the early connexion between the Universities and the Church of the Middle Ages. While the unauthorized use of naval and military uniform is forbidden by special enactment, no such legislation exists with regard to academic or ecclesiastical dress. Tailors, it is said, have been largely the arbiters of style in this matter, and following their own fancy, or the fancies of their customers, they have throughout the centuries been constantly modifying the dress. A good example of this is found, the report states, in our own day at Aberdeen. The undergraduate gown worn by men was fixed by the *Senatus Academicus* in 1860 on the fusion of King's and Marischal Colleges; but when women were admitted to the university certain changes were made in the gown as adopted by women, consisting in lapels, purple epaulettes, and a red fassel on the trencher. This departure, according to the report, was entirely an idea of the robe-makers or of the first woman undergraduate who ordered a gown. The committee thinks it doubtful whether the universities have any legal redress in the matter, seeing that the various designs of hoods are not copyright, and have not been registered under the Trade Marks Act; but it is suggested that some joint action should be taken by the various universities in the matter. The subject, while of considerable practical importance, has its amusing side. If by a play upon words a school of art confers on holders of its diploma the gown and hood of Masters of Arts, there would appear to be possible justification for a pharmacist, for example, dispensing medicines habited in medical gown and hood.

#### A SPECIAL COURSE OF MEDICAL HYDROLOGY.

As briefly announced in our columns last week (p. 703), a course of lectures on medical hydrology for medical practitioners and senior students, supplemented by demonstrations in London and by clinical instruction at Harrogate, has been arranged by the University of London Extension Board in co-operation with a joint committee of the International Society of Medical Hydrology and the Balneological Section of the Royal Society of Medicine. The course will begin on Tuesday, May 29th, and end on Saturday, June 2nd. The University of London will grant a certificate of attendance to those who have attended the whole course, taking both theoretical and practical work. Unless otherwise stated, the following lectures will be delivered at the University of London, South Kensington. On the morning of May 29th Dr. Leonard Hill will lecture on the physiology of cold, light, and heat, and Dr. R. Fortescue Fox on the qualities and actions of medicinal waters. On the afternoon of the same day there will be a demonstration of different forms of baths in the Hydrological Department, Special Surgical Hospital, Ducane Road, Shepherd's Bush, by Mr. H. S. Souttar, Dr. J. Campbell McClure, and Dr. Arthur S. Herbert. On May 30th Dr. R. Fortescue Fox will lecture on the action and uses of baths, Dr. Wilfrid Edgecombe on the treatment of cardio-vascular affections by waters and baths, and Dr. Charles W. Buckley on the hydrological treatment of rheumatism, gout, infective arthritis, and fibrositis. On the same day Dr. Leonard Hill will give demonstrations at the National Institute for Medical Research, Hampstead, on the recording kata-thermometer and other methods of controlling open-air treatment, on methods

of investigating the local action of baths, and on the wind tunnel and moving platform for studying the effect of the cooling power of air during exercise. On May 31st Dr. R. Fortescue Fox will lecture on the applications of hydrology to incipient and chronic disease, and Dr. Rupert Waterhouse on the treatment of nervous disorders by waters and baths. A study tour to Harrogate will begin on May 31st, when members of the course will leave by train from King's Cross at 1.40 p.m.; hospitality will be provided by the medical practitioners of Harrogate. On the evening of arrival a dinner and conference will be held. Next day an address will be given by Dr. J. Campbell McClure and a paper on the Harrogate waters will be read by Dr. David Brown. Demonstrations and short lectures on various bath procedures will be given at the Royal Baths by Dr. Geoffrey Holmes, Dr. Kerr Pringle, Dr. William Bain, Dr. E. Solly, and Dr. J. Liddell. There will also be a clinical demonstration of cases at the Royal Bath Hospital, and a demonstration at the pathological laboratory by Dr. Sinclair Miller and Dr. F. B. Smith. The members of the course will return to London on Saturday, June 2nd. Applications to join the course should be made, and the fee of three guineas paid before May 21st, to Dr. W. Edgecombe, University Extension Department, University of London, Imperial Institute Road, South Kensington, S.W.7.

#### SIR HENRY GRAY.

The profession in the North of Scotland and, indeed, throughout Great Britain will receive with very mixed feelings the announcement that Sir Henry M. W. Gray, K.B.E., C.B., surgeon to the Aberdeen Royal Infirmary, has accepted the appointment of chief of the surgical staff of the Royal Victoria Hospital, Montreal. On the one hand they will congratulate Canada on having obtained his services, and Sir Henry Gray himself on the wide scope which the great McGill Medical School and the splendidly appointed Victoria Hospital will offer him; but on the other they will regret that Scotland and Aberdeen should lose a teacher of such well deserved popularity and a surgeon of so much originality and skill. He was for several years consulting surgeon with the British armies in France, and was afterwards one of the surgeons who most actively seconded the work of Sir Robert Jones as Inspector of Military Orthopaedics during and after the war. In both capacities he added many more to the host of friends he had already won.

#### THE CASSEL HOSPITAL FOR FUNCTIONAL NERVOUS DISORDERS.

The Hospital for Functional Nervous Diseases, founded and endowed by the late Sir Ernest Cassel, two years ago began to receive patients suffering from the affections commonly, if not academically, spoken of as neurasthenia, nervous breakdown, and nervous prostration, who belong to the educated classes but are unable to pay the charges of nursing homes. Both the site of the hospital—Swaylands, near Penshurst in Kent—and the arrangements are admirably suited for this purpose, and the medical director, Dr. T. A. Ross, has an expert knowledge of the mental disorders of the patients who are treated in these attractive surroundings. The first medical report, just issued, shows that there are in addition two medical officers, one of whom is a woman, and that the resident secretary, Major H. B. T. Hume, is indefatigable in providing amusements and distractions, such as dancing, concerts, plays, and outdoor games, for the patients. The period under review is from May 23rd to December 31st, 1921, and deals with 144 admissions and 109 discharges, 20 of the latter being unsuitable for treatment at Swaylands, either because they had organic disease or because their mental disorder was of too pronounced a character to be dealt with in the hospital. At first sight the date of the subject-matter of the report may seem rather remote. The reason is that it was considered impossible to make an estimate of the results of the treatment until the patient had left

the hospital, and had been submitted to the strain of ordinary life for at least six months. Of the 75 patients whose subsequent condition has been ascertained 26 consider that they are quite well, and 23 report that they are very much improved; of the latter some were in the hospital for a short time only, and it should be noted that although patients occasionally lose all their symptoms in a few weeks, such a recovery is apt not to be permanent, and in most instances a residence of two months is advisable. The report contains interesting analyses of the individual cases; among the nineteen patients who did not derive any benefit from the treatment, five came with the idea that one month was all that was necessary to obtain a cure, and did not remain more than five weeks, and six others were after a time found to be unsuitable and were discharged.

#### THE ROYAL MEDICAL BENEVOLENT FUND.

The annual meeting of the Royal Medical Benevolent Fund will be held at the Royal College of Physicians, London, on Monday, May 7th, at 4 p.m. The meeting will be addressed by Sir Thomas Barlow, President of the Fund, the Archbishop of Canterbury, Lord Sumner, and Sir Humphry Rolleston, President of the Royal College of Physicians. The number of new applications for help received by the Fund increases year by year, and in 1922 was nearly double that in the previous year. The Committee of the Fund makes it a rule not to refuse any application from an eligible applicant whose income is less than £80 a year. Owing to the increased number of applicants and the larger grants made necessary by the fall in the value of money, the Fund incurred a deficit of £1,754 last year, and if it is to continue its work increased support in the form of annual subscriptions is urgently needed. The maximum grant to any case in any year is £25. The cases, as those who read the reports in our columns from time to time know, are often most pitiable, and the limited amount the Fund has at its command is something of a reproach to the profession.

#### THE EDINBURGH CONGRESS.

The fourth British Congress of Obstetrics and Gynaecology, held in Edinburgh at the end of last week, was well attended and highly successful. The whole of the two sessions on the first day was occupied by a very spirited discussion on intrinsic dysmenorrhoea, which is reported elsewhere in this issue. The second day was given up to the reading of short papers and the exhibition of specimens; we hope to publish next week an account of these proceedings. On Saturday morning operations were witnessed at the three gynaecological wards of the Edinburgh Royal Infirmary, and in the afternoon the members relaxed the bow by playing golf or making short motor excursions to the beautiful surroundings of Edinburgh. The next congress is to be held in London in 1925 at the invitation of the Obstetric and Gynaecological Section of the Royal Society of Medicine. The chief subject of discussion on that occasion will be the cause and prevention of death from puerperal septicaemia.

The annual dinner of the Indian Medical Service will be held at the Trocadero on Wednesday, June 20th. Tickets and all particulars may be obtained from the joint honorary secretary, Colonel J. J. Pratt, I.M.S. (ret.), 63, Addison Road, Kensington, W.14.

The Oliver-Sharpey lectures will be delivered before the Royal College of Physicians of London by Dr. H. H. Dale, F.R.S., on Tuesday, May 1st, and Thursday, May 3rd, at 5 o'clock on each day. The subject is the activity of the capillary blood vessels and its relation to certain forms of toxæmia.

PROFESSOR G. H. F. NUTTALL, M.D., and Sir W. J. P. have been appointed to represent the University of Cambridge at the ceremonies connected with the centenary of the birth of Pasteur which will be held at Paris and Strashourg in May.

## SOME CLINICAL RESULTS OF THE USE OF INSULIN.

### A REPORT TO THE MEDICAL RESEARCH COUNCIL.

LAST week (April 21st) a brief statement was published in the *BRITISH MEDICAL JOURNAL* (p. 695) of the conditions under which insulin could now be purchased for use in Great Britain; and at the same time reference was made to an earlier paper in the *BRITISH MEDICAL JOURNAL* (January 6th, 1923, p. 8) in which the original Canadian workers had given an account of their clinical experience in the insulin treatment of about fifty cases of diabetes mellitus. The present statement is only a general summary of the clinical experience of workers in certain hospitals in England and Scotland who have already had the advantage of using insulin prepared, under the directions of the Medical Research Council, in the laboratories of the medical schools attached to each hospital.

Latterly samples of insulin prepared by commercial firms have also been used for these clinical investigations, and the results have been found to be identical with those obtained with the products of the various research laboratories. The clinical workers have nowhere attempted the quick treatment of a large number of diabetics. At each hospital they have tended rather to select two or three severe cases of this disease and to study very closely the influence of insulin upon the patients week by week, following out the changes in blood sugar, in respiratory exchange, and in general metabolism, all in great detail with reference to a dietary controlled by precise measurement. The ultimate results of these investigations may throw light upon the metabolic derangements underlying the phenomena of diabetes, and individual papers relating to this work at the various research centres will doubtless appear in course of time. But other physicians wishing to begin the treatment of patients with the insulin that is now available from commercial sources may find some help in an account that presents the general experiences of those who have hitherto been using the product in this country.

### NATURE OF TESTS AND GENERAL RESULTS.

Insulin has been used clinically at eight different hospitals for a period of study of about three months at each. The total number of diabetics treated has been small, less than fifty, and it included only seven examples of coma. Except in the cases of coma the patients have all shown admirable improvement just as was described by the Canadian workers. The blood sugar falls rapidly as the temporary result of each injection, and sugar may be prevented from appearing in the urine even on a diet so generous as to be three or four fold as great as that which the patient could previously tolerate. There is a steady increase of weight together with a sense of greater warmth and energy. The phenomena usually ascribed to deficient metabolism of fats are especially influenced. Acetone vanishes from the breath and aceto-acetic acid from the urine; lipaemia disappears; acidosis and dyspnoea are at once controlled.

It is, however, necessary to insist, by way of caution, that these immediately satisfactory results have been obtained only with insulin. Some other commercial extracts of the pancreas that may at present be bought in the market, for hypodermic or other forms of administration, were tested and found to be totally inert in respect of any power to produce the least fall of blood sugar, even in a rabbit.

No substitute has yet been found for the hypodermic method of giving insulin. The injections have to be repeated at least once each day. They can control all the ordinary phenomena of diabetes, but the effect of each injection is only transient. As yet there is no satisfactory evidence—time has hardly allowed of that—to show that diabetes in its most serious forms can be completely cured by insulin. It may be that the great majority of severe cases cannot hope for more than prolongation of life, with greater strength and ampler dietary, but only at the cost of continuous treatment with insulin.

### INSULIN AND ITS ADMINISTRATION.

The insulin is procured by alcoholic extraction of pancreas from the abattoirs. By a complicated alcoholic fractionation, and other processes of fractional precipitation, the active con-

stituent is obtained in a state of relative purity, and is put up in sterile watery solution with a trace of antiseptic added. Ampoules of solution should be kept in the cold wherever possible. The injection should be made with a fine needle, preferably under the skin of the upper arm. A slight tingling or discomfort may be caused for a few minutes, but no prolonged effects of local irritation or reaction have occurred, and the same place may be used again and again for injections.

The unit dose is not measured by reference to the weight of substance taken into solution, but by determining the volume of final solution required to reduce the blood sugar of a 2-kilo rabbit under standard conditions to about 0.04 per cent., at which level convulsions appear. Three units, as at present defined, produce this effect in a rabbit; or the units may be calculated by observations on mice under similar standard conditions. The average single dose for an adult patient is 10 new style units, but the administration should always be guided by thought in units rather than in the so-called doses.

In a healthy subject, starved previously for fifteen hours and remaining without food, 30 units will cause a fall of blood sugar commencing in less than half an hour and progressing for about three hours. The fall may be from the normal level of about 0.12 per cent. or 0.1 per cent. down to 0.05 per cent., near which level definite and serious features of sugar deficiency are likely to appear. A larger dose of insulin is required to produce this critical fall in the healthy human being, where the liver is full of stored glycogen, than in an emaciated diabetic. In the latter a rapid fall in blood sugar and the development of hypoglycaemic features do occur much more readily. The similarly produced insulin hypoglycaemia in a rabbit is attended by convulsions, coma, and muscular flaccidity. The rabbit remains apparently moribund, and without treatment may die in an hour or two; but the intravenous injection of glucose solution at this stage will in a couple of minutes restore an unconscious and convulsed animal into an apparently normal creature that will probably begin at once to nibble food again. Subcutaneous injection of glucose solution is equally effective, though ten or fifteen minutes are then needed for recovery. The parallel phenomena of insulin hypoglycaemia in the human patient are described later. They can be checked at once by the administration of glucose, but their occurrence should be avoided altogether by carefully attending to the time when insulin is given in relationship to food.

### ADMINISTRATION IN RELATION TO FOOD.

Insulin should never be given during periods of abstinence from food. Glucose reaches the blood very soon after a meal, and continues to do so for two or four hours, varying with the nature of the meal, whether carbohydrate or protein. The effect of insulin lasts for a period up to eight hours, but there is little danger of serious features developing after the fifth hour. Therefore each injection should be followed by a meal in about a quarter of an hour, and fresh food should be given every three or four hours subsequently until the insulin effect has passed beyond such activity as might reduce the blood sugar to a seriously low level. It is obviously safer to give two small doses at fully spaced intervals rather than one large dose daily, and a large dose should never be given in the evening, for serious changes might arise unnoticed during the time of sleep and abstinence from food. One worker found that one unit of insulin could provide for the efficient consumption of 2 grams carbohydrate taken as such in the food of a completely diabetic patient. Protein food contains nearly half its weight of potential carbohydrate, so that the same dose of insulin should provide for at least 4 grams of protein. But the carbohydrate from protein enters the blood much more slowly than does that of carbohydrate food taken directly as such. Moreover, diabetic patients vary greatly in the amount of insulin required to cover the food taken, while even the individual patient may vary from time to time in his needs. It is therefore impossible at present to state the doses of insulin needed in respect of any scale of diet. Each patient must be tried separately with regard to his own individual requirement, and the dosage subsequently watched for possible changes in the amount needed.

### CLINICAL FEATURES OF HYPOLYCAEMIC COLLAPSE.

The results of an excessive dosage of insulin were rarely seen. At two of the centres there was no experience at all of them. Other workers saw them to a moderate degree, particularly in cases where diabetic patients were given

insulin during periods of starvation for the purpose of studying its influence on the standard metabolism.

The reaction, which usually appeared three or four hours after insulin injection, commenced often with a sense of weakness, sometimes associated with free perspiration. Faintness, dizziness, and mistiness of vision were added to this; and the patient might either feel drowsy, as though going quietly under an anaesthetic, or show intense anxiety from the sense of rapidly advancing and overwhelming weakness. The nervous reflexes were simply depressed but not otherwise changed. The blood sugar was then usually down to 0.06 or 0.05 per cent. Prompt recovery in ten or fifteen minutes was easily obtained by giving glucose from 10 to 20 grams, or about 1/2 oz. drunk in 3 or 4 oz. of water. Cases that through lack of proper vigilance might have been allowed to pass into unconsciousness would require subcutaneous or intravenous injections of glucose solution (5 per cent. in normal saline). Milder cases at the onset of collapse can be treated by cane sugar. Glucose is not essential except for intravenous injection.

No fatalities from this cause have been observed in Great Britain, and the experience of the first three months would suggest that the danger from it is slight. That happy result is, however, not to be taken as evidence that the danger is negligible but rather to be ascribed to the close attention that was given daily to these patients and to the repeated measurements of their blood sugar curves. Unnoticed changes in the sugar variation of a diabetic might easily occasion a serious insulin collapse; or the reaction might follow from some quite trivial chance, such as a patient for some reason or other leaving uneaten the meal that was ordered to follow an injection of insulin.

An instance that did occur in one hospital ward recently may be quoted in full, since it illustrates emphatically the great need of care in using this new and powerful method of treatment.

*Case A.*—A man, aged 62, who had suffered from diabetes mellitus for seven years. He was greatly emaciated. He had ataxia of the legs, the knee-jerks were absent; he presented Romberg's signs and optic neuritis. The Wassermann reaction was negative. There was no evidence of cerebral tumour. During nine days after admission the patient was kept on 53 grams of fat, 84 grams of protein, and 107 grams of carbohydrate, in order that his ketosis might improve. This it rapidly did. He retained on the average about 50 grams of carbohydrate, the urine sugar averaging between 50 and 60 grams per diem.

April 4th. The fasting blood sugar was 0.33 per cent. The administration of insulin began, 10 units being given three times a day. Diet consisted of 108 grams carbohydrate, 85 grams protein, and 54 gram of fat. The urine on this date became free of sugar.

April 5th. Thirty units of insulin. At 3 p.m. patient says he has been perspiring since 2 p.m., especially noticeable on the head. He feels rather sick and irritable, but seems quite well.

April 6th: Yesterday's urine was free from sugar and acetone. Usual dose insulin 10 units given at 6 a.m. Patient feels well this morning, but is even more hungry than usual. Feels quite well but rather tired. 1 p.m.: 10 units insulin given. Usual dinner. 2.30 p.m.: The patient got up to shave and wash. He returned to bed about 3 p.m., and felt a glow going all over him and he began to perspire, felt slightly sick and very irritable. At 3.30 p.m. he had a short sleep—he said he had a feeling of apprehension. 3.45 p.m.: The patient awoke in a violent rage, swearing and shouting at another patient in the room for no apparent reason. He was perspiring profusely. Eyes staring. Speech very thick. No twitching. Pulse feeble but not rapid. Whisky 1 oz. in 180 c.cm. hot water given. Patient drank this easily and said he felt better, though he began to feel shivery. Face looked very congested and the veins on temples were very prominent. Pulse improved after the stimulant but patient gradually became more helpless and said he felt "drunk." Saliva dribbling. 4.10 p.m.: The patient cannot hold his head straight (falls to right side), great difficulty in swallowing, the tea coming down his nose. He ate half an egg and a little tea (usual dose of insulin not given). At 4.15 p.m. he was much paler, skin still very moist and cold; cannot speak at all. Unable to swallow. 5.15 p.m.: Patient quite unconscious; incontinence of urine. Blood taken for sugar = 0.09 per cent. Moaning continually, with occasional very loud groans (almost a roar). Cannot swallow glucose prepared. 6 p.m.: Intravenous injection of glucose, 45 grams in 450 c.cm. normal saline solution. 6.5 p.m.: Groaning stopped, and patient opened his eyes and became very restless. 6.10 p.m.: Consciousness regained; dribbling of saliva stopped. Patient began to speak, saying that his throat was sore and he felt very cold. Glucose, 25 grams in 240 c.cm. water, and lime-juice given by mouth and swallowed easily. 7 p.m.: Patient sitting up in bed, feeling well and hungry and much warmer. He remembers nothing from the time when his tea was brought in at 4 p.m. until 6.30 p.m. He remembers the onset of the attack very distinctly, and says he knows he lost all control and was shouting and swearing when the attack came on. He says the irritability seemed to "come over him in waves,"

leaving him with a feeling of nausea. 7.15 p.m., patient ate supper—egg, cauliflower 100 grams, omelette 30 grams, butter 15 grams, 2 cups of coffee, cream 60 c.cm.

April 7th. Patient feeling very much better. On previous day the urine contained 6 grams sugar, although 154 grams carbohydrate, 74 grams protein, and 108 grams fat had been taken in diet.

Since April 8th only small traces of sugar have appeared in the urine, in spite of the diet consisting of between 140 to 150 gram carbohydrate, 78 grams protein, and 150 fat. There has been a steady improvement, blood sugar remaining at about 0.150 per cent., but on a number of occasions there have been signs of hypoglycaemia. These usually occurred in the late afternoon. The amounts of insulin vary between 20 and 30 units per day. It is apparent in this case that symptoms due to hypoglycaemia occurred very readily as during the severe attack the blood sugar had only decreased to 0.09 per cent.

If insulin be given to patients in such amounts as to keep the urine free from sugar the dosage must be frequently checked by blood sugar determinations. And for all cases under insulin treatment glucose or cane sugar must be kept ready at hand, so that a small quantity may be given to the patient as soon as any premonitory symptoms of hypoglycaemia are noticed.

#### SELECTION OF PATIENTS FOR TREATMENT.

The instructions drawn up by the Committee advising the Ministry of Health upon the use of insulin require that there shall be no luxury use of this product until supplies are abundant. Mild cases of glycosuria or diabetes are therefore excluded, and with these would automatically be classed those cases (renal glycosuria) where sugar is present in the urine for three or four hours after food, owing to excessive permeability of the kidney, though the blood sugar is not raised above the normal percentage, and the patient remains otherwise in good health. It is obvious that whenever insulin becomes available for the treatment of mild cases, great care will need to be exercised in the exclusion of such cases of renal glycosuria from insulin administration since they would be likely to show early and dangerous hypoglycaemic collapse.

All ordinary diabetics should, in the first place, be put on a restricted diet with some periods of starvation—as, for example, by the Allen or Graham procedure—and their treatment continued simply in this way on the lines established by workers in the years immediately preceding the introduction of insulin. If the diabetes is not of long standing and the patient not greatly wasted, this treatment would probably suffice, or might need only slight assistance later with insulin. But if the disease is of long duration, with proved excess of blood sugar, and the patient fails after starvation to tolerate any diet of less value than about 1,000 calories in two or three hours, so that strength and weight continued to fall seriously, then insulin should be given systematically.

The cases hitherto treated at the research centres have all been of this severe type. The reasons for this choice were two: In the first place, the supply of insulin made at each hospital laboratory was small, and it was naturally reserved for those patients who were so seriously ill that without the aid of the new treatment they could not have been expected to live many months longer. Secondly, these serious cases, in whom failure of ordinary treatment by dieting over a long period had proved the almost complete decay of the patient's natural mechanism for the proper metabolism of carbohydrates and fats, gave an opportunity for demonstrating clearly and at once in each individual case the powerful effect of insulin against the background of complete diabetes. In or acute cases of diabetes often recover so well during a first course of dietetic treatment without any aid from insulin that it would have been necessary to study a considerable number of them in order to demonstrate convincingly the effect of insulin.

The method of controlling the diet varied in the different centres, and it is needless to discuss the details of each because every physician has developed in the course of his experience in the treatment of diabetes his own individual rules for the construction of a dietary; and there was, in one instance, to which reference is made later (Case C), suggesting that a special arrangement of the proportions of foodstuffs may be combined with the action of insulin in a way as to lead to a sustained improvement in the patient's tolerance of carbohydrate. The general experience is that insulin acted simply as a temporary instrument to enable a diabetic to eat a certain amount more of food than he had previously tolerated without the appearance of sugar or ketones in the urine and without a rise in his blood sugar. Each dose of insulin, therefore, enabled him to

energy out of the food and to increase the reserve stored up in his tissues as evidenced by increase of weight. Only a progressive increase of weight over several weeks was accepted as proof of tissue increase, for there was reason to believe that part of the increase of weight was due simply to increased retention of water in the body.

The following cases are quoted, briefly, to illustrate the doses of insulin needed in severe cases:

**Case B.**—Woman, 56 years old, with steadily progressive and very severe diabetes. During the last eighteen months she had repeatedly undergone dietetic treatment in hospital, at first with immediate success, but ultimately tolerance could not be established on any diet sufficient to maintain life.

After five days' continued starvation, the urine became sugar-free. The subsequent tolerance was of a diet of only 190 calories in twenty-four hours.

By the administration of 60 units of insulin each day she was enabled to tolerate 1,350 calories daily, with 80 grams carbohydrate, and her weight was raised in ten weeks from 5st. 10lb. to 7st. During the day the urine was sugar-free and contained no acetone bodies on this diet; but each morning the blood sugar was over 0.4 per cent., and the urine contained sugar and a trace of ketone from the failure of her own unaided metabolic processes during the night.

**Case C.**—Man, aged 18, with severe diabetes for three years. On a diet of 100 calories, containing 20 grams carbohydrate, he excreted 30 grams of sugar daily. With insulin, about 12 units daily, he could tolerate a diet of 1,400 calories daily, containing 48 grams carbohydrate, the urine being sugar-free and the blood sugar below 0.2 per cent. His weight and strength have steadily increased.

**Case D.**—A very severe case, who had been kept just alive for the two months preceding insulin treatment on a diet of 600 to 800 calories daily. On this he was excreting large amounts of sugar and ketone bodies, and seemed unlikely to survive many weeks. Insulin twice daily enabled such increase of diet to be made that there was a gain of weight of 15 lb. in the first fortnight. He was eventually raised to 2,500 calories with 70 grams carbohydrate, upon which, with slight glycosuria, he was able to return to work while continuing insulin injections twice daily.

The doses in severe cases may be from 10 to 20 or even 30 units twice a day, or a smaller amount divided between three doses. Patients with so grave a form of the disease plainly ought to be treated at first in special institutions, where the diet can be closely controlled and the blood sugar frequently determined. If, after treatment has commenced, only one measurement of the blood sugar is made occasionally, it should be from a sample taken at the same time daily and three hours after the injection of insulin and the consumption of a meal directly related to that injection. With such precautions it may be possible to give enough insulin to keep the urine entirely sugar-free, and that condition would seem to be the ideal aim when hopes of ultimate cure or real amelioration are entertained. The essential principle in the treatment of diabetics by diet control alone has been generally recognized to be the avoidance of hyperglycaemia and glycosuria, so that the intrinsic powers of carbohydrate metabolism may be slowly regained in the long period of comparative rest from overstrain. Insulin ought to aid this rest period. But if insulin is given in such amounts as to prevent the appearance of sugar in the urine, there are no means of estimating the full effect of the dose except by watching the blood sugar. If the latter cannot be done sufficiently often it is probably safer to avoid the danger of hypoglycaemic collapse from too much insulin by reducing the dose to such a level as will just allow the patients a slight glycosuria as a safety gauge. In such conditions the patient will put on weight and recover strength, though on a road that may not be the quickest way to cure.

Real improvement was reported in one case, and here the physician believed that the good result had been attained by the exclusion of all carbohydrate as such from the increased diet under insulin. This method was not tried by the other workers, who had all allowed some carbohydrate food to their patients.

**Case E.**—A man with severe diabetes, which had not yielded to that dietetic treatment some works previously in hospital. On that 360 calories, with 16 grams carbohydrate, he passed from 25 to 30 grams of sugar daily. The blood sugar at 9 a.m. was 0.24 per cent.

He was given insulin, 12 units, each day at 9 a.m. with a meal the first meal being at 6 a.m. The 9 a.m. blood sugar gradually fell to 0.15 per cent. It was then found that three hours after

12 units of insulin the blood sugar had fallen to 0.055 per cent. The daily dose of insulin was consequently reduced to a lower level at 8 units daily. There was no glycosuria for three weeks and only a small amount of ketone bodies persisted.

Subsequently the insulin was reduced to 4 units daily, upon which a diet of 2,000 calories, consisting chiefly of protein and fat with carbohydrate as vegetables, is tolerated without glycosuria and with a blood sugar of 0.11 to 0.13 per cent.

It is obvious that if this dietetic method is proved to be generally applicable there will be a great economy in the use of insulin as well as a better hope of real cure. It is a most expensive method of feeding a patient when carbohydrate is given under the protection of insulin, the latter costing at present nearly 3s. for the control of 30 grams or one ounce of carbohydrate food when eaten by a patient with complete diabetes.

#### THE TREATMENT OF COMA.

Only 7 cases have been treated at the various centres, and they appear to fall into two clinical groups.

##### *Coma in Diabetes.*

First come three cases of coma in diabetes, developing as the result of surgical operations in not very severe diabetics. In all these the blood sugar during the coma was very high, from 0.7 to 0.8 per cent.; air hunger and dyspnoea were not conspicuous clinical features, though unfortunately this was not checked by measurements of the alveolar carbonic dioxide or of the alkaline reserve of the blood; there was but little acetone in the breath and not much aceto-acetic acid in the urine. The cases were therefore of coma with great hyperglycaemia, but not with severe ketosis. No improvement was obtained with insulin, though only in one case was the substance given in sufficient amount to reduce the blood sugar, and it is therefore only in the latter that failure need be admitted. The other two instances should be discarded: in one of them insulin was injected too late when the circulation had practically failed, and in the other the blood sugar of 0.78 per cent. was virtually unaffected by 30 units of insulin.

**Case F.**—A woman of 70, with gall stones but no obvious liver disease, with arterio-sclerosis, and slight diabetes. She passed into coma directly after an operation in which the gall stones were removed. After five hours of coma the blood sugar was 0.79 per cent. Dyspnoea moderate, with faint odour of acetone in the breath and only a slight ferric chloride reaction in the urine. No extensor response or other neurological physical signs.

Insulin was given subcutaneous'y in repeated doses of 30 or more units. Five hours later, after a total of 105 units had been given, the blood sugar was 0.4 per cent. Saline solution had also been given freely. There was absolutely no clinical improvement, and the patient died ten hours later. *Post-mortem* examination was refused. Clinically the condition appeared to be that of simple coma, though other possibilities cannot be rigidly excluded.

##### *Ordinary Diabetic Coma.*

The second group of cases, four in number, was that of ordinary diabetic coma not related to surgical operation, and showing a much lower blood sugar, 0.3 to 0.4 per cent., but greater air hunger, with depression of the alveolar CO<sub>2</sub> and with an abundance of ketone bodies in the urine. Further observations are needed before the contrast suggested between the two groups, of surgical coma in diabetes and of ordinary diabetic coma respectively, can be established. But it is obvious that the patients in the second group showed ketosis rather than hyperglycaemia, and in this group three out of four were improved in a very striking way by insulin.

**Case G.**—A man was admitted to hospital on the verge of diabetic coma, being just conscious, and with extreme air hunger as shown by the big respiratory movements of his abdomen and chest. The blood sugar was 0.33 per cent., a figure often seen in ordinary diabetics while in fair health; but the alveolar CO<sub>2</sub> was 1.1 per cent., a reading so low that in the experience of the physician in charge of the case always meant death within about twelve hours, for he had never seen recovery in any patient with alveolar CO<sub>2</sub> lower than 1.8 per cent.

Insulin, 18 units, was given; and abundance of water (15 oz. hourly), together with sodium bicarbonate 2 drachms by the mouth every two hours for three doses. In two hours the patient began to feel better, and his air hunger was lessening at the third hour. At six hours the blood sugar was 0.11 per cent. and the alveolar CO<sub>2</sub> had risen to 2.7 per cent. The patient recovered and now has a morning blood sugar of 0.15 per cent. on 12 units daily of insulin,

and a diet of 53 grams protein, 105 grams fat, and 16 grams carbohydrate in vegetables. There has been no glycosuria for three weeks.

**Case H.**—A boy admitted in diabetic coma, with air hunger and low bicarbonate reserve in the blood. Insulin given, but no sugar. Death.

**Case I.**—A young woman of 25, in coma, with air hunger, acidosis, and blood sugar of 0.4 per cent. She was given insulin subcutaneously, 10 units every three hours; at the same time fluid was given freely and glucose solution both intravenously and subcutaneously. The blood sugar was thereby raised to the very high figure of 1 per cent. The patient recovered.

The last case (Case I) raises a paradox for discussion. Sugar is sometimes given together with insulin in cases of diabetic coma, with the intention of preventing the comatose state from being further aggravated by hypoglycaemic collapse. Now it appears from the cases quoted that coma may arise when the blood sugar is not unusually high, and also that the patient may emerge from coma though the blood sugar has been raised by added glucose to 1 per cent. On the other hand, a case (Case F) of post-surgical coma with high blood sugar was not improved, though the blood sugar was reduced to 0.4 per cent. by insulin. The percentage of blood sugar, therefore, appears to bear no direct relation to the state of diabetic coma.

It is, however, impossible to neglect a comparison between the states of diabetic coma and hypoglycaemic collapse, the latter being an entirely novel conception that has come into pathological thought as the result of experience with insulin. The hypoglycaemic collapse is caused by the artificial lowering of the blood sugar to half its normal level for health, and it is at once relieved by giving sugar. The brain is therefore as sensitive to the withdrawal of sugar as to sudden diminution in its oxygen supply. It may be that one aspect of the picture of diabetic coma is due to the final inability of the brain cells to consume sugar, even though this food be presented to them in abundance in the blood. Insulin might restore their metabolic power, and their functional recovery might conceivably be aided by artificially increasing for a short time the amount of blood sugar upon which they can commence to feed.

At any rate, whatever the theory, experience has suggested that, in the treatment of diabetic coma with insulin, glucose should be given simultaneously, either by the mouth or by the stomach tube or even intravenously. The insulin can generally be administered by hypodermic injection. In cases of extreme circulatory collapse, it can be used intravenously without danger. In all cases fluid should at the same time be given, but not much in excess of half a pint every hour, so that the patient on recovery from the coma shall not fall into danger of death from pulmonary oedema.

The scanty experiences quoted suggest that post-surgical coma in diabetics is difficult to treat. Obviously, the best way is to avoid its occurrence altogether by careful preparation of the patient before the operation, dietetic control and insulin being used together to free the urine of ketones and sugar. There is no evidence available upon the course of such prophylactic treatment, or upon how the action of insulin may be influenced by the proceedings connected with surgical operations.

Other complications of diabetes, such as sepsis, tuberculosis, or peripheral neuritis, can presumably be influenced by insulin as favourably as they are by ordinary dietetic control, when the latter succeeds in abolishing glycosuria. But on this aspect of the general malady no evidence has been collected, for the first investigations in British hospitals were restricted to simple, though serious, instances of diabetes.

A FUND has been opened in commemoration of the Dutch gynaecologist Hector Treub to support investigations in gynaecology and obstetrics. Subscriptions should be sent to the president of the fund, Dr. C. C. Delprat, 98, Jan Luykenstraat, Amsterdam, or to the secretary, Dr. H. H. van der Berg, 808, Keizersgracht, Amsterdam.

THE French congress of oto-rhino-laryngology will be held at the Hôtel de la Société de Géographie, 184, Boulevard St. Germain, Paris, under the presidency of Professor Jacques of Nancy, from May 7th to 9th, when the following subjects will be discussed: (1) Nasopharyngeal fibromata, introduced by MM. Sébilleau, Moure, and Laurens; (2) radiography in oto-rhino-laryngology, introduced by MM. Reverchon and Worms. Further information can be obtained from the general secretary, Dr. G. Liébault, 216, Boulevard St. Germain, Paris.

## Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

### The Budget Debate.

THE various points of view taken by the different speakers in the debate on the Budget have extended the survey without adding much to the general knowledge. The Chancellor was able, as usual, to point out that much of the criticism directed against the proposals was mutually antagonistic and to claim that he was pursuing the *via media* of safety between the Scylla of excessive taxation and the Charybdis of baseless optimism as regards the necessity of debt repayments. In this connexion the remarks we made last week as to the desirability of the greatest possible accuracy in the Treasury forecasts are very much in point. Mr. Baldwin may have with him the concurrence of general opinion in thinking that a Sinking Fund of £40,000,000 represents a just balance between the two conflicting schools of thought, but if there is ground for the criticism made that the Treasury has been unduly cautious in its estimates of income from taxation—and the arguments in favour of that contention have considerable force—it may well be that the close of the present financial year will show that the Chancellor's path has led him definitely to the debt-reducing side of the controversy. In that case the general body of taxpayers—and the income taxpayer in particular—will have ground for feeling that a more accurate, or less pessimistic, forecast would have lightened his burden, and that a longer continuance of inflated surpluses will necessitate some drastic reconsideration of our financial procedure.

### Parliamentary Medical Committee.

At a meeting, on April 23rd, of the Parliamentary Medical Committee, of which Dr. F. E. Fremantle is chairman and Sir Sydney Russell-Wells secretary, it was decided to appoint a subcommittee of five members to represent to the Minister of Health the desirability of widening the power of access to the first register for existing nurses on terms suggested by Dr. Chapple, as follows:

The Council may accept for registration upon the first register of nurses any applicant who presents—

- (a) A certificate of good character;
- (b) A certificate signed by the matron of a general hospital or by two medical men setting out that the applicant has been in attendance upon the sick in the capacity of a nurse for a period of not less than three years prior to November 1st, 1913; and
- (c) A certificate signed by three medical men (one of whom shall be on the staff of a general hospital) setting out that the applicant has adequate knowledge and experience of medical and surgical nursing, and is competent to attend upon the sick in the capacity of a nurse.

Provided that the Council may require the nurse as a condition precedent to registration to present herself for special examination as to competency and fitness before a medical officer or officers appointed by the Council.

The subcommittee was also asked to suggest to the Government the appointment of a Select Committee to inquire into the dissatisfaction in the nursing profession owing to the failure of the Registration Act to function in a number of respects.

Communications were received thanking the committee for the work it had done in connexion with the Dangerous Drugs Bill.

### Insurance Medical Service.

The Minister of Health stated, on April 18th, that as a result of discussion with the Insurance Consultative Council, it was not now contemplated that any general rearrangement of the insurance medical system would be made. Certain modifications of the terms of services had been recommended by the Council, but these would not involve any substantial change in the present system. No case had, in his view, been made out for a separate investigation of the kind suggested, which would complicate, and so tend to delay a settlement. Sir Kingsley Wood wished to know whether, in respect of the payment to doctors on the panel lists, the Government actuary had advised that at the end of the existing agreements it would no longer be possible for the present payment of 2s. 6d. a patient per annum to be made from the funds of the approved societies; and whether the Minister of Health proposed that any further contributions should be made from State funds in connexion therewith. Mr. Chamberlain said that the Government actuary had given no advice on the matter referred to, subsequent to that contained in his report on the financial provisions of the National Health Insurance Act, 1911. The answer to the latter part of the question was in the negative.

Sir Kingsley Wood asked, on April 23rd, whether the statement of the Minister of Health had been drawn to a committee recently issued by the British Medical Association to deal on the panel lists entitled "Organization of Insurance Practitioners in consideration of, and in the event of, a refusal of the terms offered by the Government for National Health Insurance work," which contemplated a refusal in certain contingencies to carry on the panel service; and whether he would state what action he proposed to take in such a contingency. Neville Chamberlain replied that the communication to which Sir Kingsley Wood had referred was understood to be a confidential circular issued only to insurance practitioners, and he had no personal knowledge of it. Negotiations with representatives of insurance practitioners with a view to the revision of their terms of service

had been begun, and the prospects of a successful issue would not be enhanced by any statement at this stage as to the step the Government might find it necessary to take in a contingency which he had every reason to hope would not arise. Sir Kingsley Wood also asked whether the Government actuary advised in 1922 that at the end of the existing agreements with doctors on the panel it would no longer be possible for the present payment of 2s. 6d. per patient per annum to be continued to be paid from approved societies' funds; and whether he had given any further report or advice since that date. Mr. Chamberlain replied that in reporting on the financial position of the National Health Insurance Bill of 1922 the Government actuary did not give the advice which he merely indicated his opinion (that it should safely be borne) applied strict should not be held to imply that larger or more protracted additional charges could be borne by the societies. No further report or advice had since been received from him on the subject.

Mr. R. Murray asked whether Insurance Committees in England had power, not conferred upon Insurance Committees in Scotland, to pay the expenses of complainers and witnesses attending meetings of Medical Service Subcommittees. Dr. Elliot replied that the position in Scotland was met by the provision made in Article 32 (6) of Medical Benefits Regulations for the holding of local inquiries.

**Liquor Traffic Prohibition Bill.**—Mr. Scrymgeour, to whom the ballot gave the sitting of April 20th for debate on the second reading of his bill for Liquor Traffic Prohibition, presented the case in a speech of an hour and a half. The motion was seconded by Dr. Salter, who, however, said that he did not believe that the machinery or method of the bill were good. He was, he said, more concerned to put before the House the case for prohibition as he regarded it from scientific and sociological standpoints. He claimed some assistance from the course so lately taken by the house in passing the bill to amend the Dangerous Drugs Act. Dr. Salter was emphatic in his contention that prohibition in America has not tended to drug addiction, stating that the official declarations were all in a contrary sense. Finally, in that connexion he quoted Sir Arthur Newsholme, who recently paid a special visit to America in order to inform himself on this particular point, and reported that there was no evidence whatever that prohibition had caused an increased consumption of drugs in substitution to alcohol. Colonel Sir Arthur Holbrook led off the opposition to the bill, quoting *inter alia* the opinion of Sir James Crichton-Browne as to the value of alcohol. Viscount Curzon seconded the rejection. In the course of the debate Dr. Chapple declared himself opposed to the bill, but said he was not opposed to prohibition by local option, because when a small community was ripe for this change he would allow it to make the change without having the liquor traffic imposed on it by votes from outside. Each centre could thus become a demonstration centre. He believed that ultimately prohibition would come by way of the local vote. The bill was rejected by 236 votes to 14.

**Medical Herbalists (Registration) Bill.**—Commander Kenworthy introduced, on April 23rd, a bill "to provide for the registration of medical herbalists"; it is backed by Mr. Mosley and Mr. Linfield; it was given first reading and ordered to be printed.

**Housing Bill.**—Mr. Neville Chamberlain explained the provisions of the Government Housing Bill on April 24th. The proposal is that the Treasury shall give to the local authority a subsidy of £6 per house per year for twenty years, the size of the house to be limited to a maximum of 850 superficial feet in the case of a two-storied house, and 750 for a flat or one-storied house.

**Board of Control.**—The Minister of Health, on April 23rd, informed Mr. Ammon that the committee upon the nursing service in county and borough mental hospitals, appointed by the Board of Control in March, 1922, hoped to report shortly, and the Board of Control did not consider that at this stage it would be desirable to add to its membership. The Joint Conciliation Committee had already been informed that the Nursing Committee would be willing to consider a statement of any views which the Mental Hospitals Association and the National Asylum Workers' Union would desire to put before them. Mr. Ammon further asked whether in view of the fact that the Board of Control had no legislative power and could not enforce their recommendations on the visiting committees, the Minister would consider the advisability of abolishing the Board of Control and transferring its present functions to the Ministry of Health. Mr. Chamberlain said that the powers of the Board of Control and their relation to local authorities and to Parliament were fully considered when the Board was established, and he did not think there were adequate grounds for initiating measures to alter the present arrangement.

**Veneral Disease in the British Army.**—Sir S. Russell-Wells asked, on April 19th, the rates of veneral disease admissions in 1921 and 1922 of the British Army on the Rhine, in Constantinople, and in the United Kingdom; whether there was any difference in the methods of medical prophylaxis adopted, and whether any steps were taken to prevent soldiers attending civil veneral clinics in plain clothes in the United Kingdom. Lieut.-Colonel Guinness replied that the ratios per 1,000 were:

	1921.	1922.
British Army of the Rhine	212.34	213.53
British Army in Constantinople	228.48	81.41
United Kingdom	40.26	31.66

The same methods of medical prophylaxis were followed at each of these commands. As regards the last part of the question, the Ministry said there was no prohibition on the attendance of men at such clinics, but they would probably find medical attendance, whether in plain clothes or in uniform, difficult in practice.

## COCAINE SUBSTITUTES COMMITTEE.

THE Home Office and the Ministry of Health have had under consideration the possibility of the use of substances which might serve the same therapeutic purpose as cocaine, but be free from its deleterious properties. The Minister of Health, after consultation with the Medical Research Council, has appointed a committee "to investigate the comparative value, for the therapeutic purposes for which cocaine is at present used, of various possible substitutes, and the evidence as to risk, if any, of such substitutes becoming drugs of addiction." The committee will consist of:

Dr. J. SMITH WHITAKER, a senior medical officer of the Ministry (Chairman);  
Dr. NORMAN G. BENNETT, surgeon, Royal Dental Hospital, London;  
Dr. R. W. BRANTHWAITE, a Commissioner of the Board of Control;  
Dr. T. CARNWATH, a medical officer of the Ministry;  
Dr. J. H. CHALDECOTT, senior anaesthetist to St. Mary's Hospital, Paddington, nominated by the Anaesthetics Section of the Royal Society of Medicine;  
Dr. H. H. DALE, of the Medical Research Council;  
Mr. T. B. LAYTON, surgeon in charge of the Throat and Ear department of Guy's Hospital, nominated by the Laryngological Section of the Royal Society of Medicine;  
Dr. G. F. MCLEARY, a medical officer of the Ministry;  
Mr. R. FOSTER MOORE, surgeon, Royal London Ophthalmic Hospital, nominated by the Ophthalmological Section of the Royal Society of Medicine;  
Sir WILLIAM HENRY WILLCOX, nominated by the Home Office.  
The secretary is Dr. E. W. ADAMS, Ministry of Health, Whitehall, S.W.1, to whom all communications relating to the work of the Committee should be addressed.

## England and Wales.

### ROYAL PORTSMOUTH HOSPITAL.

At a meeting of the Committee of Management of the Royal Portsmouth Hospital on April 13th, Mr. C. P. Childe, senior honorary surgeon, was unanimously elected chairman of the Committee of Management. Sir Harold Pink, in proposing his election, said that Mr. Childe was a member of the town council, and this year he had declined the office of Mayor because of his work in connexion with the forthcoming Annual Meeting of the British Medical Association to be held in Portsmouth under his presidency. Mr. Childe, in returning thanks after his election, said that he was not absolutely new to hospital administration, as for two and a half years during the war he was administrative officer of the 5th Southern Hospital of 1,000 beds, and this experience had given him some knowledge of the work. Up to July his time would be taken up in preparing for the British Medical Association, and until that time he looked forward to the support of his vice-chairman. He regretted that Sir Harold Pink had vacated the chair, because during his four years of office the hospital had been raised out of low water, and for the first time for many years was now out of debt. The late chairman had also been connected with the War Memorial improvements, which had cost £10,000. Mr. Childe added that he looked upon his appointment with pride, because it was the first time that an executive officer had been called upon to fill the highest position at the hospital. He felt that this was evidence of the good feeling existing between the two departments.

### DR. ARNOLD LYNDON.

Dr. Arnold Lyndon of Grayshott, Surrey, who at the end of last year retired from active practice, has been presented by his friends and patients with a specially made inlaid mahogany bookcase, a typewriter, and a pair of field glasses as a grateful acknowledgement of his many services. The gifts were accompanied by an album containing the names of the subscribers. The balance of the money subscribed has, at Dr. Lyndon's request, been presented to the Grayshott Nursing Association, to form a reserve fund which could be drawn upon when necessary to keep the district nurses' cottage in repair. Dr. Lyndon has long taken an active part in the work of the British Medical Association; he is a member of the Central Council and of several committees and subcommittees, and is a past-president of the Surrey Branch. He is chairman of the Surrey Local Medical and Panel Committee, and a member of the Surrey Voluntary Hospitals Committee. He also served on the Central Medical War Committee.

## LEICESTER ROYAL INFIRMARY.

The 150th anniversary meeting of the governors of the Leicester Royal Infirmary was held on April 18th, when the annual report for 1922 was submitted. During the year 3,809 in-patients were admitted to the Infirmary, and 4,478 to the Children's Hospital, the average number of beds occupied being 255. The average cost per occupied bed was £182, and the average cost per in-patient £11 9s. 10d. In the out-patients' department 41,987 out-patients and 70,461 accidents were treated; in the x-ray department there were 4,872 attendances, and in the orthopaedic department 17,687. Of the new cases attending the venereal diseases department 429 were males and 239 females; 5,345 pathological examinations and reports were made. The total ordinary income of the infirmary for 1922 was £51,510, as compared with £51,104 in 1921; the extraordinary income was £8,275. The total income for the year was therefore £59,785, against £61,111 in the previous year, but the financial position was better than in 1921, owing to the reduction of expenditure brought about by the fall in prices and by the demand for close economy. The net result of the year's working was a deficit of £2,665, as compared with a deficit of £5,981 in the previous year. In response to the £100,000 appeal fund for building improvements donations amounting to £60,000 have been received.

## Scotland.

## PRESENTATION TO DR. BYROM BRAMWELL.

It will be remembered that on the occasion of his 75th birthday last December the many friends of Dr. Byrom Bramwell desired to express in some concrete way the high esteem, respect, and admiration in which he is held by asking him to sit for his portrait. The response to the appeal for subscriptions was so good that it has been found possible to commission Mr. David Alison, R.S.A., to paint two portraits—a larger and a smaller. The presentation will be made at the Royal College of Physicians of Edinburgh on Saturday, May 19th, at 5.30 p.m. The larger portrait is a three-quarter length, sitting, in which Dr. Bramwell is wearing the robes of Past President of the Royal College of Physicians, Edinburgh. The smaller portrait is about half-length, and in this case Dr. Bramwell is wearing the same robes, but the hood of the Royal College of Physicians is replaced by the hood of the LL.D. of Edinburgh University. Sir Humphry Rolleston, K.C.B., President of the Royal College of Physicians of London, and Sir David Drummond of Newcastle-on-Tyne, have very kindly undertaken, at the request of the committee responsible for raising the fund, to make the presentation to Dr. Bramwell; one of the portraits is to be retained by himself, and the second is to be presented to the Royal College of Physicians, Edinburgh, and will be received on their behalf by Sir Robert Philip, President of the College.

## GLASGOW MEDICAL LUNCH CLUB.

A meeting of this club was held on April 19th in Ferguson and Forrester's Restaurant, with the President, Dr. W. L. Reid, in the chair. The members had with them as the guest of honour Dr. J. Stanley White of London, who gave an address on "The ductless glands." Dr. White made good use of the limited time at his disposal, and gave a rapid review of the therapeutic value of the various glandular extracts, referring more particularly, though shortly, to thyroid, parathyroid, pituitary, suprarenal, ovary, and pancreas. Many helpful hints were thrown out in passing for their use, alone or in combination, in certain diseases. These were much appreciated by the members.

## THE EMBELLISHMENT OF PRINCES STREET, EDINBURGH.

The town council of Edinburgh last week considered a report by the city architect for the construction of a terrace promenade on the south side of Princes Street at an estimated cost of £50,000. The general idea of the plan is to construct a retaining wall which would enable the existing pavement to be extended over the breadth of the present unsightly sloping bank of earth leading down to the gardens. The wall would be topped by a handsome balustrade of which the dies would carry ornamental lamp pillars. Towards the broad walk at the base of the wall in the gardens the wall would be pierced at certain points by arched openings to form

alcoves which would provide shelter from the rain. The shelter provided by the wall and its direct exposure to the south would make the broad walk a very desirable promenade for invalids. It is also suggested that a site for the Central which it has been proposed to erect on the lines of that at Westminster should occupy a prominent and central position in the terrace. The existing public statues would be included in the scheme as well as two new statues to be placed at staircases leading down to the gardens.

## Ireland.

## INSURANCE ADVISORY COMMITTEE.

At the first meeting of the newly constituted National Health Insurance Advisory Committee in Dublin, Sir Joseph Glynn, chairman of the Commission, presided, and Dr. W. J. Maguire and Mrs. Dickie, commissioners, were present, with the principal officers of the department.

The Chairman, in his opening statement, explained that an advisory committee had been set up in the early days of the working of the Insurance Acts, but owing to the intervention of the great war and other causes it had fallen into desuetude. As a result of representations made to the Commissioners by approved societies and others, the authority of the Minister of Finance was obtained for the establishment of a new committee, to consist of twenty-five members. The chairman also explained the basis on which representation of the various interests had been fixed, and the scope of the committee's functions. Sectional meetings of the committee would be held from time to time where special interests were affected, and the whole committee would be summoned when general lines of policy were under consideration, or discussions affecting more than one particular interest were taking place. He explained the position created by the passing of the Irish Free State Act, 1922, and the steps that were being taken by the Commission to cope with it. A bill had been prepared and submitted to the Minister, which it was hoped would shortly be introduced in the Oireachtas. Full and detailed instructions would be issued by the Commission to all concerned. He next referred to the question of non-compliance with the Acts in the matter of the stamping of cards. Suggestions were made for tightening up the procedure for effecting compliance. Medical certification was next dealt with, and as a result of discussion thereon it was agreed between the representatives of the approved societies and of the medical profession that they would bring before their respective associations the question of forming a committee of medical men and societies' representatives, who would discuss and submit to the Commission proposals for effecting improvement in the present system. The chairman pointed out, in connexion with medical certification, that it had now become necessary to consider where the financial provision therefor, which was hitherto made from Exchequer funds, was to come from.

The following resolution was adopted on the motion of Dr. Rowlette, seconded by Mr. Hutchinson:

"That this Advisory Committee is of opinion that the administration of the National Health Insurance Acts is hampered by the dissociation of medical treatment—domestic and hospital—from the administration of the Acts, and urges that a system should be established by which adequate treatment would be provided for the classes affected by the Insurance Acts."

The following resolution was proposed by Dr. Rowlette, seconded by Mr. Kevin O'Duffy, and adopted:

"Inasmuch as the financial provision made for medical research by Section 16 (2) (b) of the National Insurance Act, 1911, is no longer available, this Advisory Committee wishes to impress on the Government the desirability of making adequate provision for medical research."

The representatives of the medical profession on the National Health Advisory Committee are Dr. H. J. Rowlette and Dr. T. Hennessy (Irish Medical Secretary, British Medical Association); Dr. M. F. Cox (President of the Royal College of Physicians) and Dr. Horace Law are appointed the representatives of the Dublin hospitals.

## THE MURDER OF DR. P. McILDOON.

An appeal is being circulated on behalf of the widow and young children of the late Dr. Patrick Muldoon of M.M. co. Leitrim, who was recently murdered by armed men.

Dr. Muldoon was dispensary doctor of the Mohill district, and part-time medical attendant to the Free State troops stationed in the locality. His widow and young children are left entirely unprovided for, and it is hoped the appeal will meet with the success it deserves. In the course of the appeal it is stated:

"The poignancy of the sad event is only realized by those who know what his untimely demise means to his afflicted wife, left with a helpless family. Dr. Muldoon had hardly begun his professional life, and his skill, combined with a generous and open-hearted personality, was promising a brilliant career, when his untimely death intervened to cut it short. It is hardly necessary to point out that Dr. Muldoon had not had the time or opportunity to provide for his dependants in the unforeseen circumstances which have befallen. His widow has three children—the eldest only 4 years old—for whom to provide. To his friends, therefore, we appeal with confidence. We know they will show their appreciation of his excellent qualities, and their sympathy with Mrs. Muldoon and her helpless family. To his medical brethren and the general public, to whom Dr. Muldoon was less known, we appeal with scarcely less confidence. Their sympathy has not been denied to his widow, and we venture to think that very many will be glad to take this opportunity of giving that sympathy practical expression."

Subscriptions may be sent to the Very Rev. Canon Masterson, P.P. (Mohill, co. Leitrim), *Treasurer*, Dr. Charles Dolan, or Dr. Thomas Reynolds, M.B. (Ballinamore, co. Leitrim), *Secretaries*.

## Correspondence.

### CUPPING.

SIR,—It is curious enough, as Dr. Gubb remarks, that this mode of minor therapy should be so much oftener resorted to in France than in Britain. An interesting and rather amusing paper could be written about the practice of medicine in the two countries and pointing out the differences in practice arising out of similar theories. In France, if your patient dies from pneumonia, Madame la Concierge will look very severely on you if you have not applied ventouses. Her British equivalent most likely will if you have.

While endorsing Dr. Gubb's remarks as regards the indications of cupping, I rather differ from him on the question of technique. Can "nothing be better" than the kitchen tumbler? For ventousing purposes I would suggest using ventouses. In the short knob projecting from the bottom lies the whole secret of the gentle art of cupping.

Shall we use cotton-wool or spirits? Both. Twist a short bit of wire round a small pad of cotton-wool which is to be soaked and lit. Now clench your left fist. Insert the knobs of three cups between your fingers and keep the cups quite close to your patient's skin, leaving just space enough for your torch. In goes the flame, down comes the cup. I would not allow more than five seconds for the fixation of the three, and twelve cups ought to be applied easily within a minute, a matter of importance when we have to avoid exposure to cold.

With a young lady you will do wisely to abstain from cupping of any description. If the cup has been of any use it leaves a long-standing ecchymotic bruise turning gradually from scarlet to green, which offers a prolonged opportunity of studying the problem of haemoglobin and the blood pigments. Indeed, quite recently a French author has stated that if a cup leaves a purple scar on a pneumonic patient the outlook is favourable, but if a brownish one there is no hope of recovery. Considering the actual tendency towards measurements and the vogue of colour scales, cupping might be the first step towards *prognosimetry*—the art of fixing handicaps!—I am, etc.,

Viehyr, April 22nd.

GUSTAVE MONOD, M.D., M.R.C.P.

SIR,—I was greatly interested to read Dr. Gubb's paper on cupping (April 14th, p. 639), for it recalls to me the episodes of the early sixties, about which era I was a pupil with a cousin in the Edgware Road. A patient had some congestion of the kidneys and cupping was recommended; at that time there was a professional cupper named (if memory serves correctly) Betts; his methods were extremely skilful, for he used a tube filled with some absorbent material which he dipped in spirit, lighted, quickly thrust it into the glass, withdrew it, and then in a second placed it on the required spot; there was thus no danger of burning the skin, and the flesh rose well into the glass; then the scarifier was applied, and the glass readjusted as before. When I joined Dr. Dewes in

1872 I found both cupping glasses and scarifier, and I had them among my armamentaria until I left Coventry. As a rather painful method of abstracting blood it was effective, and, if it did not have a very curative effect on the disorder, its moral influence must have been remarkable and lasting.—I am, etc.,

Eastbourne, April 18th.

MILNER MOORE, M.D.

### BLOOD PICTURE IN SPRUE.

SIR,—Dr. Vincent Coates's interesting article (April 21st, p. 677), on pernicious anaemia with foci of infection in the alimentary tract, deals with some important questions.

I wish here to refer only to Dr. Coates's second case, an instance of sprue. The blood changes recorded are not infrequent in sprue, and the blood may be indistinguishable from ordinary pernicious anaemia and yet recovery occur. I should not consider that the blood picture in this case is of the aplastic type, as Dr. Coates suggests. Polychromatophilia, anisocytosis, poikilocytosis, and nucleated red cells are recorded, and this degree of change in the red cells is too great for aplastic anaemia.

The case which Sir Percy Bassett-Smith referred to at the Medical Society had a colour index of 1 (approximately) with 1,000,000 red cells. This cannot be considered a low colour index in view of the erythropenia.

Not much attention has been paid to the blood changes or to the achlorhydria in sprue, or in chronic colitis, but these points are obviously of importance in the treatment. They are also of interest, as Dr. Coates remarks, in the investigation of pernicious anaemia.—I am, etc.,

London, W., April 23rd.

H. LETHBY TIDY.

### PERNICIOUS ANAEMIA.

SIR,—Dr. Coates's paper in your issue of April 21st (p. 677) seems to call for some comment from the point of view of the haematologist.

I submit that there is no evidence that any of his cases were true pernicious anaemia in the pathological sense. In none were megaloblasts found, and in the autopsy on Case 3 there is no mention of the presence of free iron in the liver or of the essential changes in the bone marrow. If we take as the evidence of pernicious anaemia merely a marked reduction in the number of red cells with a few normoblasts and a colour index above 1, many cases of secondary septic anaemia will be included. I think that Dr. Coates has not excluded this diagnosis in the cases he quotes. To satisfy a pathological diagnosis of pernicious anaemia I submit that there must be the presence of megaloblasts persisting in repeated examinations as well as a marked reduction in the total red cell count and a colour index above 1, and, *post mortem*, at least free iron in the liver and an increase in the area of the red bone marrow with a marked megaloblastic reaction therein.

Doubtless sepsis (for example, from a haemolytic streptococcus) is one of the causes of true pernicious anaemia, but in very many cases, probably the majority, the infection stops short of a lethal change in the bone marrow. To this latter the term "pernicious anaemia" should, I think, be confined.—I am, etc.,

London, W.C., April 21st.

A. KNIVETT GORDON, M.B., B.C.,  
B.A.Cantab.

### TREATMENT OF PUERPERAL INFECTIONS.

SIR,—I have read the interesting article on puerperal fever by Professor B. P. Watson—an old fellow student of mine—and must say that his modern views appear to be diametrically opposed to the old teaching of the Edinburgh school. Possibly I did not pay as much attention to the lectures as Professor Watson, but one thing I do remember was the old midwifery axiom, "Leave to Nature—or empty the uterus." On this principle I have always worked with considerable success, and I am afraid I shall continue to do so. Apparently Professor Watson thinks the latter part of the axiom unnecessary.

Professor Watson most emphatically states that on seeing a case of pyrexia after childbirth digital exploration of the uterus is not indicated. Of course, other conditions must be excluded, and this any ordinary man would do; but then, I say most strongly, one should make sure that the uterus is empty. This is especially important nowadays when the certified midwives do almost all the ordinary work, and the practitioner is only called in when something goes wrong, often being sent for on a rise of temperature.

Some few months ago I was casually asked to see a case by midwife, on the fifth day, owing to a slight rise of temperature (101°). I was informed that the patient had influenza (of which there was a case in the house) and required no examination, but just the proverbial "bottle of doctor's medicine." The midwife stated that the placenta was perfect and the confinement quite

normal. Therefore I agreed, but the next day the temperature rose to 106.8°, and I removed with my fingers a piece of putrid placenta as large as my hand—the temperature then falling to normal (see chart). The woman died on the seventeenth day with secondary abscesses and sepsis. I feel sure that could I have removed this source and cause of infection early the woman would have lived.

I have seen this kind of case so often, and, as a rule, the marked recovery after evacuation and thorough cleansing of the uterus is astounding. Every practitioner knows this to be so, especially in incomplete abortions. As students we were shown a temperature chart as an example of a fall by crisis in sapraemia where retained placenta had been removed. Probably Professor Watson has forgotten this chart. My case shows the same thing.

Professor Watson discards the old classification of sapraemia and septicaemia, but Professor Munro Kerr states they do exist clinically as two distinct forms—the one condition being early and due to retained products, whilst the other occurs later on when the infection becomes generalized. He also states that saprophytic organisms lower local and general resistance and permit pyogenic organisms to multiply and gain entrance to the uterine tissues. He advises the removal of debris and repeated intrauterine douches (Fairbairn, p. 592). Bacteriologically organic tissues aid the growth of some organisms—for instance, testis for spirochaetes. Why should not placental tissue act in the same way, helping to form a septic factory?

One of my cows recently calved, appeared to be very ill, and my man informed me that she had not "cleaned" properly. Therefore I encouraged him to try and clear her, which he did with a wisp of straw and a cleaning douche. The immediate recovery of the cow followed. I do not understand why a portion of the after-birth so often gets trapped in man and beast alike.

I quite agree that to scrape the whole of the uterus out with a sharp curette is wrong, and opens up fresh surfaces for infection. But as a rule one's fingers and a gauze swab are sufficient, although a soft blunt flushing curette, a warm douche, or an application of iodized phenol will help in cleansing and purifying the source and culture bed of the bacteraemia. Professor Watson does not agree, and states that retained placenta does not predispose to bacterial infection. But I think no woman can be well with a portion of decomposing placenta inside the uterus, and will often die if left alone. Small bits of membrane do not matter, but placental tissue should always be extracted at once. If retained placenta is left it will provide plenty of work for gynaecologists later on.

I must apologize for writing contrary to the teaching of such an eminent authority; but most practitioners have their own views and practical methods for treating such cases, and Professor Watson invites discussion.—I am, etc.,

Lowestoft, April 4th.

DUDLEY W. BOSWELL, M.D., D.P.H.

#### CONGENITAL HYPERTROPHY OF THE PYLORUS.

SIR,—After reading Dr. Still's paper published in your columns on April 7th it seems worth while to record the after-history of the case which I reported in the *Lancet*, January 10th, 1903. This was, I believe, the first case ever recorded

as having recovered with simple feeding alone, without operation or lavage.

It was an absolutely typical case fulfilling all the diagnostic requirements. The patient is now an Oxford undergraduate; he has just taken second-class honours in Mods., and rows the Torpids. He never suffers from indigestion in any way, and is well grown, strong, and healthy.—I am, etc.,

Shrewsbury, April 18th.

H. WILLOUGHBY GARDNER.

#### PHTHISIS: COMPLETE AND PERMANENT RECOVERY.

SIR,—Fifty years ago this month Dr. Andrew, of St. Bartholomew's Hospital, told me I had phthisis, both lungs were affected, and I must leave the hospital at once, and on his certificate the College allowed the session.

I went to the country, got well, returned to Bart's in October, but relapsed at the end of the session. Intending to winter at Davos I went to Paris, attended the Hôtel-Dieu, and determined to observe carefully the conditions under which I was worse or better, to avoid or counteract the former and live under the latter. By this means I got well in 1876—chest girth increased nearly five inches and vital capacity over 200 cubic inches—and have remained well.

The investigation was continued, and I laid the results before the British Association in 1886-87, and I demonstrated the practicability of the work in 1890-1915 by giving the measurements of 100 cases of chest and lung development, and the results of scientific treatment in 100 cases of phthisis—complete recovery in early cases, recoveries and arrests in cases more advanced, and great relief and some temporary arrest for months or years in cases still further advanced.

This experience is unique in the history of phthisis, and I venture to think it should be placed on record.—I am, etc.,

London, S.W.

GODFREY W. HANBLETON, L.R.C.P.

#### THE TRAINING OF NURSES IN SMALLER AND COTTAGE HOSPITALS.

SIR,—With reference to Dr. Flemming's letter (April 21st, p. 699) the committee of our small hospital considered the regulations of the General Nursing Council for training unsatisfactory, and in consequence some months ago made a reasoned statement to the Ministry of Health upon the subject. But that infant prodigy, the General Nursing Council, appears to have been born with a swollen head and also to suffer from defects of hearing and of vision.—I am, etc.,

St. Albans, April 23rd.

SIDNEY CLARKE.

#### "HICCUP."

SIR,—The note in the *BRITISH MEDICAL JOURNAL* of April 7th (p. 603) on epidemic hiccup surprises me much. During all the years I have been in general practice I have had several cases of intractable hiccup and I am firmly of the opinion that the diaphragmatic spasm is due to rheumatism; for many years I have never failed in curing the most obstinate case within a very short time by exhibiting a few doses of antirheumatic medicine such as 15-grain doses of sodium salicylate without the addition of any sedative. I have never had a case of encephalitis lethargica, but firmly believe that it has the same etiology and would respond to intensive antirheumatic treatment. Of course—as stated in your article—morphine preparations will relieve any spasm, but there is great satisfaction in relieving symptoms by treating the disease causing them.—I am, etc.,

Manchester, April 22nd.

MARTIN J. CHEVREUX.

#### Universities and Colleges.

##### UNIVERSITY OF CAMBRIDGE.

THE following candidates have now satisfied the examiners in both parts of the examination for the Diploma in Public Health:

D. FASU, L. S. CHATTERJI, J. A. J. COPELAND, N. D. DUNCAN, H. H. FINDLAY, A. T. GAILLARD, C. H. GUNARAKA, J. C. S. HILL, S. HUNT, FLORENCE S. KIRK, HILDA J. LALDLOW, F. LOPE, P. R. A. MORTON, L. R. RAY, ANNABELLA A. REID, MARY B. BENTRICE M. SELLAR, Y. SEN, ANNIE F. SOMERFORD.

\* Distinguished in the principles of Hygiene.  
† Distinguished in the application of Sanitary Science.

THE following candidates have satisfied the examiners in the Diploma in Medical Radiology and Electrology:

Part I (Physics and Electrotechnics): M. A. AGA, R. M. BAKER, J. BOWEN, B. L. W. CLARKE, L. R. G. DE OLIVEIRA, M. FRIZEN, S. G. H. T.

W. H. Hastings, J. F. James, M. D. Joshi, Anna T. Kellock, Jane S. Knight, G. J. Luyt, A. G. MacLeod, Margaret J. Moir, H. S. Rajan, A. Ross, W. H. Rowden, Jessie E. Sheret, E. W. Twining, S. B. Warden, E. V. Whitby. *Part II (Radiology and Electrology):* M. A. Add, E. G. Barker, J. E. Bowen, B. L. W. Clarke, H. K. G. Hodgson, J. F. James, Jane S. Knight, H. S. Rajan, W. H. Rowden, J. P. Thierens, E. W. Twining.

#### UNIVERSITY OF LONDON.

The following were successful at the examination for the Diploma in Psychological Medicine, with special knowledge of Psychiatry:

A. C. Hancock, W. D. Nicol.

#### UNIVERSITY OF GLASGOW.

At the graduation ceremony on April 17th the Straits Settlements gold medal for thesis for M.D., on a subject in connexion with tropical medicine or tropical hygiene, was presented to Dr. Thomas J. Mackie; the University Arnott prize for examination in physiological physics to William A. Burnett, B.Sc., and the Asher Asher gold medal (special class prize) for laryngology and rhinology to Mr. Murdo Nicolson.

At the graduation ceremony held on April 21st the following degrees were conferred:

M.D. (with high commendation): M. A. Macintosh (in chemistry), M.B., Ch.B.—J. S. Young, Milloy, H. P. W. Skinner, W. P. Grieve, J. A. Bingl, B. T. Allison, J. C. Anderson, Isobel C. Armstrong, R. Armstrong, R. W. S. Ashby, A. A. Bain, A. Barr, W. P. Blackstock, (Miss) George I. Brodie, J. E. Brown, Henrietta Buchan, J. A. Cameron, J. Campbell, M. A. Cassidy, Isabella P. Crosbie, T. Cullen, W. R. Cumming, T. Dagg, R. A. M. Davidson, W. W. Dawson, Alice M. S. Dewar, W. M. Dinwoodie, I. M. K. Donaldson, J. F. Dunn, J. T. G. Even, G. M. C. Ferguson, Margaret I. H. Ferguson, J. Fine, T. Fisher, W. Fordyce, L. P. Foyer, W. Fraser, Janet M. Gibson, R. E. S. Gibson, Jane T. Gilmour, J. G. Graham, A. Gray, Catherine M. Gray, Miriam Greenberg, J. Hamilton, J. J. Hargan, Jessie H. Harkness, W. M. C. Harrowes, Janet G. Harvey, W. C. Harvey, Irene Higgin, W. Houston, W. M. Johnston, G. MacG. Kay, D. A. Kerr, Elizabeth C. Kerr, Janet B. Kerr, A. King, H. T. Kirkland, Mary D. Lambie, Christina S. Lamont, T. Leckie, J. A. Lister, J. M. Logan, Margaret E. R. Loudon, G. H. Macartney, A. M. Maccallum, J. M. Callum, Margaret S. L. M. Cash (in absentia), J. A. W. M. Cluskie, J. A. M. Crossan, C. M. Donald, C. F. H. M. Fadyen, J. M. Ghee, Janet H. Mackay, B. L. Mackay, Joan D. Mackenzie, V. D. Macfarlane, P. M. K. McKillop, G. M. M. Lellan, Jean D. MacLennan, Doris M. J. McNab, Mary M. Naught, A. MacNiven, Evelyn M. Pherson, A. E. MacIntyre, Dorothy M. MacIntyre, Clara F. Marshall (Mrs. Gerzlen), H. W. Miller, W. B. D. Miller, R. Nisbet, A. O'Hanlon, Henrietta L. Paterson, Mary R. Peden (Mrs. Donald Macalister), F. V. G. Penman, T. Prentice, Annie B. Primrose, D. Rankine, F. Ribeiro, W. J. B. Riddell, R. W. Ritchie, G. G. Robertson, J. M. L. R. C. Ross, T. D. Ross, J. N. Russell, Katharine C. Shankland, Gladys A. G. Sharpe, Grace S. Shirraw, R. G. Simons, R. B. Simpson, A. P. Smith, J. A. Sommerville, R. G. Sprenger, J. M. Stirling, Carolina J. Tessier, Marian Thom, Annie M. Thomson, J. M. M. Thomson, A. Urquhart, V. R. Walker, R. Walkingshaw, Annie Werner, J. Whiteford, R. Wilson, S. R. Wilson, W. Wilson, R. Woodside, A. B. Wright, R. A. D. Wylie, W. L. Young, R. Yuill.

† With commendation.

## Medical News.

ON the occasion of the formal opening of the Peking Union Medical College, in September, 1921, in the tenth year of the Republic of China, there were gathered in Peking a great number of prominent men and distinguished scientists for the celebration of the event. The President of the Republic was pleased to receive them in audience, and it was a most memorable occasion. A "Jen Shou" (benevolence and longevity) medal has recently been bestowed by the President on the British representatives—Sir William Smyly, Professor R. T. Leiper, Dr. Thomas Cochrane, and Dr. A. J. Armitage—in commemoration of the event.

The London County Council has appointed Dr. Frederick Lucien Golla, physician and lecturer in clinical medicine, St. George's Hospital, to the position of pathologist to the London County Mental Hospitals and director of the pathological laboratory in succession to Sir Frederick Mott. The salary attaching to the position is £1,000 a year, with temporary additions which bring the total remuneration at the present time up to £1,234. Dr. Golla will relinquish his appointments at St. George's Hospital, but will retain that of physician to the Hospital for Paralysis and Epilepsy, Maudsley Vale.

A GENERAL meeting of the Röntgen Society will be held at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, on Tuesday next, May 1st, at 8.15 p.m., when Dr. C. Thurstan Holland will deliver the sixth Sylvanus Thompson memorial lecture. His subject is "X-rays and diagnosis." The annual general meeting will be held on June 5th.

Dr. J. H. MORRIS JONES, J.P., has been elected chairman of Colwyn Bay Urban District Council; since the recent incorporation of Llysfaen within its boundaries, Colwyn Bay has become the largest town in North Wales.

THE Home Secretary announces that as a result of inquiries made in connexion with the investigations into the illicit traffic in dangerous drugs which led to the recent conviction of H. M. F. Humphrey, he has decided to cancel the licences held under the Dangerous Drugs Act, 1920, by the firm of Messrs. Whiffen and Sons, Limited, of Lombard Road, Battersea (also trading under the name of J. A. Wink and Company), and they will not for the future be allowed to buy, manufacture, sell, or have any dealings in the drugs to which that Act applies.

THE fourth intensive course of lectures for general practitioners and senior medical students at the Central London Throat Nose and Ear Hospital, Gray's Inn Road, W.C.1, will commence on May 7th at 4 p.m., and conclude on May 17th. The fee for the course, which will be devoted to diseases of the ear, is one guinea.

A COURSE of ten lectures on ante-natal and post-natal child physiology will be given by Dr. W. M. Feldman in the Physiological Theatre of the London Hospital Medical College, Mile End, E.1, on Wednesdays at 4.15 p.m., commencing May 9th. The course is open to students of the hospital, and medical practitioners are invited to attend.

THE Secretary for Mines has appointed Professor J. S. Haldane, M.D., F.R.S., together with Professors W. S. Boulton, S. M. Dixon, C. H. Lees, and J. F. Thorpe, to be additional members of the Safety in Mines Research Board, of which Sir Edward Troup has been appointed chairman.

THE death is announced of Mr. Edwin Thomas Hall, F.R.I.B.A., well known for his designs of hospitals and sanatoriums. He was joint architect of the new Royal Infirmary, Manchester, and of the Welsh War Hospital, Netley; he designed the Frimley Sanatorium, the South Wales Sanatorium, and the King George Hospital for Wounded. He was consulting architect to St. Bartholomew's Hospital, to the King Edward VII Sanatorium, Midhurst, and to the Leeds General Infirmary.

THE meeting of the University of London for the presentation of degrees at the Albert Hall on Thursday next at 2.30 p.m. will be followed by a graduation service at Westminster Abbey at 5.45, when the Dean of St. Paul's will preach. In the evening the graduates' dinner will take place at the Grocers' Hall. On the previous evening the new graduates will be entertained at dinner by the Guild of Graduates.

THE third series of lectures to students and medical practitioners given by the medical staff of Queen Charlotte's Lying-in Hospital, Marylebone Road, N.W.1, will begin on Thursday, May 10th, at 5 p.m., and end on June 14th.

DR. P. A. MAPLESTONE, D.S.O., who is a graduate of the University of Melbourne, and has until recently been lecturer of protozoology in the Liverpool School of Tropical Medicine, has been appointed Assistant Director of the Research Laboratory at Sierra Leone. Before he sailed last week to take up the duties of his new post he was entertained at a luncheon at which members of the committee and of the staff of the school were present. Sir Francis Danson, the host, said that Dr. Maplestone would find that the foundation of a most useful organization had been laid by Professor Blacklock, who was about to come home on furlough.

PESSIMISTS among criminologists and criminal lawyers prophesied that an effect of the war would be greatly to increase crimes of violence. The statistics published this week for 1921 do not confirm this anticipation; the number of persons tried for violence against the person in 1921 was 966, as compared with 1,107 in 1920 and 1,387 in 1913. There was an increase of offences of burglary, house-breaking, and robbery from 3,984 in 1913 to 4,722 in 1920, but in 1921 there was a decrease to 4,280. The number of charges of bigamy increased from 133 in 1913 to 722 in 1920, declining to 570 in 1921. Indictments for other sexual offences numbered 1,805 in 1913, 1,607 in 1920, and 1,535 in 1921.

A COURSE of eight lectures on nutrition will be given by Professor V. H. Mottram, M.A., at King's College for Women (61, Campden Hill Road, W.8) on Mondays and Wednesdays, April 30th, May 2nd, 7th, 9th, 14th, 16th, 23rd, and 28th, at 4.30 p.m. Attendance at this course is recognized in connexion with the B.Sc. (Honours) Degree in Physiology of the University of London.

THE annual meeting of the Medical Mission Auxiliary of the Church Missionary Society will be held in the Queen's Hall, Langham Place, W.1, on Wednesday, May 2nd. The chair will be taken at 7.30 p.m. by Mr. W. McAdam Eccles, M.S. Tickets of admission can be obtained on application to the Loan Department, Church Missionary Society, Salisbury Square, E.C.4. There will be a small number of reserved seats at 1s. each.

WE regret that owing to a misunderstanding it was announced in our issue of April 14th (p. 663) that Dr. Carl Spengler of Davos had died; the announcement should have been with reference to his brother, Dr. Lucius Spengler. We are glad to learn that Dr. Carl Spengler is still living.

## Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology, Westrand, London*; telephone, 2630, Gerrard.

2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard.

3. MEDICAL SECRETARY, *Medisecra, Westrand, London*; telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegram: *Bacillus, Dublin*; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegram: *Associate, Edinburgh*; telephone, 4361, Central).

### QUERIES AND ANSWERS.

#### THE UNPLEASANT TASTE OF POTASSIUM BROMIDE.

SIR JAMES DUNDAS-GRANT, in reply to the inquiry in our issue of April 7th, 1923 (p. 616), writes to suggest that the unpleasantness may to a considerable extent be minimized by the addition of a small amount of sodium bicarbonate—say 5 grains to 10 or 15 grains of potassium bromide. For those who are very particular a few drops of liquid extract of liquorice may be added and the mixture made up with equal parts of chloroform water and peppermint water.

#### DUPUYTREN'S CONTRACTION.

"E. M. B." inquires as to the recognized treatment of an early case of Dupuytren's contraction in a man aged 24. We have referred this question to Mr. E. Muirhead Little, whose reply is as follows:

As the pathology of Dupuytren's contraction of the palmar fascia is but imperfectly known there is no certain means of arresting its development. The most hopeful method is by the use of thiosinamin in one or other of its preparations. This cannot be expected to cause the absorption of already organized fibrous tissue, but it may be hoped that it will prevent the deposition of more tissue. The form in which I have used it has been that called iodolysin, sold by Allen and Hanbury, and injected into the general circulation. One ampoule may be used once or twice a week, but the drug should not be continued for many weeks without intermission, as it has a depressing effect. I cannot say, however, that this is "the recognized treatment," the only procedures entitled to that name being operative. Of these that of Adams by multiple small subcutaneous incisions and stretching gives good results in the hands of some surgeons. The alternative method is, of course, open excision. In any case the patient should frequently stretch the fingers himself. The treatment of this condition is not included in the latest published work on orthopaedic surgery by Jones and Lovett. The occupational etiology of the disease is no longer generally held, its symmetrical distribution and the great preference it shows for one finger in particular (the third) as the site of its first appearance, suggest a central origin.

#### INCOME TAX.

"G. E." has been asked by the inspector of taxes for vouchers all for his motoring expenses; it is impossible to comply with this request so far as cash purchases are concerned, and these have been considerable. He also asks whether it is allowable to claim motoring expenses at so much per mile.

\* \* The inspector of taxes has no personal right to call for evidence of expenses, but he can call the attention of the district commissioners to the figures, and they can require evidence in support of an appeal against any assessment they may think proper to make. We therefore suggest that "G. E.'s" best course is to send the inspector what receipts he can find and explain the nature and probable extent of the cash purchases. A mileage rate is of little use for stating the expenditure incurred, as it must be an estimate, and what the statutes require is a statement of the actual facts. It may be of some use in showing the reasonableness of the figures supplied, but obviously very much must depend on the nature of the car and the roads used and on other personal and local circumstances. Assuming there are no special facts, and that the year's expenditure has not been swollen by car renewal, the rate suggested seems perhaps a little high.

#### Car Transactions.

"J. C." bought a second-hand car in 1918 for £255 and replaced it in 1922 by a similar new car. He has claimed to deduct the out-of-pocket expenditure—namely, £300 less £50 allowed for the old car—that is, £250. It appears that of the £240 expended £15—that is, £300—£265, represented an improvement of his professional equipment, and to that extent there was an outlay of capital. No allowance is legally due for such expenditure, and the inspector of taxes is right in claiming to reduce the allowance from £240 to £205.

"G. L. B." bought a car in 1914 for £409 and sold it in May, 1922, for £180, replacing it in April, 1922, by a car costing £195. There is no allowance for "wear and tear" in the assessment of professional profits, but only for the cost of replacement as and when it is incurred. The maximum amount that "G. L. B." can claim is therefore the actual out-of-pocket expenditure—that is, £195—£180=£16. Strictly this is an expense of May, 1922, and would not therefore enter into the computation of the three years' average profits forming the basis of the 1922-23 assessment.

### LETTERS, NOTES, ETC.

#### WHOOPING-COUGH.

DR. W. J. MIDELTON (Bournemouth) writes: I notice Dr. Thomas Carruthers's remarks (April 14th, p. 666) concerning my suggestion for the cure of whooping-cough. At a recent meeting of the Bournemouth Medical Society a colleague said that during two epidemics of whooping-cough, acting on a hint from me, he had used *ol. crotonis* co. with gratifying success. In every case the whoop had disappeared at the end of three weeks from the commencement of the treatment. I again append the formula of *ol. crotonis* co., since I am convinced it possesses decided advantages over *lin. crotonis* B.P.

R. *Liq. epispasticus* B.P. ... .. 5*℥*  
*Ol. amygdal. dulc.* ... .. 3*℥*  
Mix. Allow ether to evaporate; filter; then add  
*ol. crotonis* *mxxl*.

#### LONDON SMOKE.

ONCE upon a time, some forty years ago, there lived at Highgate which then still retained some of the characters of a village, a lady who declared that when a yellow fog drifted up from London she could detect the smell of tobacco smoke in it. To most people the odour is flatly that of coal smoke, which is perhaps always more or less to be perceived in London air. This at any rate would seem to have been the opinion of Edward Jenner, if we may trust a note made by Farington in his diary for 1857 which is being printed in the *Morning Post*. Farington's note is as follows:

"Dr. Jenner observed to Lawrence that He could by smelling at His Handkerchief on going out of London ascertain when he came into an atmosphere untainted by the London air. His method was to smell at His Handkerchief occasionally, and while He continued within the London atmosphere He could never be sensible of any taint upon it; but, for instance, when He approached Blackheath and took His Handkerchief out of His pocket where it had not been exposed to the better air of that situation—His sense of smelling having become more pure he could perceive the taint. His calculation was that the air of London affected that in the vicinity to the distance of 3 miles."

#### A DISCLAIMER.

MR. D. McCRAE AITKEN (London) writes: May I ask the hospitality of your columns to disclaim any responsibility for an article which recently appeared in a daily paper, and to express my regret that the name of Sir Robert Jones was coupled with mine in a manner which neither he nor I could possibly sanction?

#### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 33, 35, and 38 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 36 and 37.

A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 167.

### SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	...	...	0 9 0
Each additional line	...	...	0 1 6
Whole single column (three columns to page)	...	...	7 10 0
Half single column	...	...	3 15 0
Half page	...	...	10 0 0
Whole page	...	...	20 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday preceding publication, and, if not paid for at the time, accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive and post letters addressed either in initials or numbers.

# A Lecture ON CANCER OF THE BREAST.\*

BY  
CECIL ROWNTREE, F.R.C.S.,  
SURGEON TO THE CANCER HOSPITAL.

In at least one-third of the women who develop cancer it arises in the breast, and in that event the patient's average expectation of life is not more than four years unless she is fortunate enough to detect the tumour at an early stage, wise enough to consult a medical man at once, and brave enough to submit to surgical treatment. I do not suggest that even then she will always be cured of her disease—far from it, for recurrences after surgical operation are only too frequent. But it is probably fair to say that 30 per cent. of early cases get no recurrence after radical operative treatment, and it is certainly a fact that in the remaining cases a well planned operation will generally result in the patient being spared the dreadful misery and discomfort of an ulcerating growth in the breast, the ultimate cause of death being secondary deposits in the chest or abdomen, perhaps as long as ten years afterwards.

In order that the present results of surgery may be improved the co-operation of three parties is essential. The patient must consult her doctor at an earlier stage of the disease, the doctor must make a diagnosis at the earliest possible moment, and the surgeon must endeavour to perform the most scientific and most comprehensive operation that the conditions will permit.

The need for the co-operation of the patient is sufficiently obvious to require no emphasis, but how it is to be obtained is not so clear. If it were possible for every woman to learn that cancer of the breast starts as a little insignificant lump that is always at first quite painless, and that operative treatment offers the only chance of eradicating the disease, it is certain that a very few years would show a noticeable improvement in results.

How is this desirable end to be attained? Instruction at school has been suggested, but, even if feasible, would hardly meet requirements, for after all there are other forms of cancer to be considered. But I do think that more could be done during school life in the direction of teaching the elementary anatomy and physiology of the normal body and in emphasizing the importance of seeking medical advice as soon as any departure from the normal shows itself. Another method is the diffusion of information about the early signs of cancer by means of pamphlets, leaflets, etc., as already done by some medical officers of health, and on a more ambitious scale by the Franco-American Cancer League; but this is an expensive business and appeals to much too small a public. We have, however, in the huge circulation of the daily press a vehicle for propaganda that no one can escape, and if one or more of the daily papers were public-spirited enough to devote an occasional half-column to a clear description of the early stages of the common kinds of cancer nothing but good could result.

## EARLY DIAGNOSIS.

But it is to the subject of early diagnosis that I wish to pay special attention to-day, and it is here that the co-operation of the medical attendant is so essential; he is the most important link in the chain, and upon him the fate of the patient largely depends, for it is to him that the doubtful lump is first shown, and it rests with him to decide whether the lump is in fact a lump at all, and, if so, whether it is of any serious consequence.

I see that many textbooks still describe the symptoms of cancer of the breast in the terms I remember as a student over twenty years ago—a hard, irregular mass infiltrating the breast, causing retraction of the nipple, and accompanied by enlargement of the axillary glands.

We need not concern ourselves with such cases as these except, perhaps, to emphasize the importance of never waiting until such unequivocal signs declare themselves. It is the small and insignificant tumours that must engage our attention—they provide most of our difficulties in diagnosis, and these difficulties increase, I find, for I am certainly getting a larger proportion of quite early cases than I did

some years ago. The sort of case I have in mind is a rounded mass, perhaps a quarter of an inch in diameter, movable in the breast, with no enlargement of axillary glands, no retraction of the nipple, and with no available history beyond the description of its accidental discovery the day before.

I am often asked by students whether there is not some one sign in the diagnosis of breast cancer upon which they may pin their faith and so simplify their task. There is, of course, no golden rule, but still there is a symptom which, although it is not of universal application, is of such overwhelming significance that I put it first, and a long way first, in diagnostic importance. I refer to adhesion between the growth and the skin overlying it—not the coarse and obvious infiltration met with in advanced cases, but a much more delicate involvement, resulting in a faint dimpling of the skin which is often of so slight a degree that it may only be visible after careful examination in suitable conditions of light. In its earliest stages it can be made to appear by grasping the breast on each side of the suspicious nodule and trying to push the skin away from the tumour. By then looking *along* the surface of the breast it may be possible to perceive slight irregularity in the contour not hitherto apparent. If this sign be evident—and it nearly always is when carefully looked for—I am convinced that a definite diagnosis of malignancy may be safely made with the utmost confidence irrespective of the presence or absence of retraction of the nipple, alteration in the size and shape of the breast, enlargement of glands, or any of the other classical signs of cancer. One is not likely to be misled by the adhesion of the scar of an old abscess or old operation wound, nor by the infiltration of recent inflammation.

On the other hand, absence of adhesion to the skin does not necessarily indicate that the tumour is benign, for the growth may be too small, or, if the breast be large and fat, the distance to the skin may be too great. In breasts of ordinary dimensions I have seen it present with a mass of growth no larger than a cherry-stone, but in smaller tumours than this it is not perceptible, and I think the difficulties of clinical diagnosis in this range of size are insuperable.

## Mistakes in Diagnosis.

It is worth remembering that when mistakes are made in diagnosis they are nearly always in the same direction. An early cancer, because it is so small, so painless, and so harmless-looking, is thought to be a simple cyst or simple tumour, and is either left alone to await events or at most is locally excised. On two or three occasions I have been asked to perform the radical operation upon breasts from which had been removed small tumours thought to be innocent but subsequently proved to be malignant by microscopic examination.

I have also seen a woman of 30 with metastatic cancer of the spine from whose breast a small "adenoma" had been removed two years previously, and two other patients with metastatic fracture of the femur, both of whom had primary tumours in the breast which they had been told were of no importance.

Tiny cancers, tiny adenomata, and tiny cysts are dangerously alike. Cysts may be excluded by puncture with a hypodermic needle, but I know no way of distinguishing the characters of very early solid tumours, and in these cases it is our bounden duty to excise the mass and determine its nature. A surgeon who has familiarized himself by long training in museum and laboratory with the look and the feel of pathological tissues will generally be able to decide the nature of the case as soon as he has removed the doubtful tissue and cut it across. In a few cases he may find it impossible to come to a conclusion, and in these a microscopic section must be cut.

## Frozen Sections.

I have never been able to convince myself of the value of rapid frozen sections in such cases, for, if an experienced surgeon is in doubt as to the nature of a tissue when he has a piece of it lying in his hand, it is almost certain to prove to be something out of the ordinary, and he is unlikely to get material help from sections prepared and considered by the rapid method. I feel that it is more safe to have the doubtful tissue suitably prepared by more deliberate methods and adjudicated upon in the seclusion of the pathological laboratory. Frozen sections have a very definite value in certain contingencies, but not, I think, in the differential diagnosis of obscure cases.

When faced with a difficult breast case it is always worth while considering the question of probability in relation to

\* Delivered to the Fellowship of Medicine in February, 1923.

diagnosis. Here is an analysis of the last hundred consecutive cases of primary breast disease that I have seen in private practice, and I think you will be surprised to see that I have more cases of malignant disease than all other breast diseases put together.

Subacute mastitis	...	...	...	...	8
					41

This enormous preponderance of cancer cases is no doubt partly to be explained by the fact that a certain number of them have only been sent to me for confirmation of diagnosis, for, when a woman is told that she has cancer of the breast by one surgeon, she often quite naturally asks to see another in the hope that she may get a different opinion. But in spite of this and other factors which tend in my list to put the cancer incidence too high, the general conclusion is inevitable that cancer is the commonest breast disease, and that a doubtful tumour in the breast, no matter how small and insignificant, is by the law of probability much more likely to be cancer than anything else.

*Mastitis.*

Another point arising out of my analysis that occasions some surprise is the small proportion of cases of chronic mastitis that I see. So much has been written about chronic mastitis that there is apt to be a totally false impression as to its frequency. I admit that it is a matter of some difficulty for me to obtain exact figures as to its relative frequency, for the cases attending my clinic at the Cancer Hospital obviously undergo as much or nearly as much selection as those in my private practice, and any statistics based upon them would certainly underestimate the proportion of cases of mastitis; but none the less I have come to believe that it is a relatively uncommon disease—almost certainly less common than cancer itself. The whole subject of mastitis is admittedly one of great difficulty and is fruitful in controversy; in fact, I am not sure that even yet there is any general consensus of opinion among surgeons and pathologists as to what really are the clinical characters and pathological appearances of chronic mastitis. It appears to me that there is often some confusion between chronic interstitial mastitis and subacute mastitis, although I believe them to be quite separate clinical entities with very different characters.

*Subacute Mastitis.*

Subacute mastitis is characterized by more or less sudden onset and by involvement of one and only one sector of the breast; it is always painful, it is generally unilateral, and it may be caused by such minor injuries as accompany games of golf or tennis or by vigorous spring cleaning. It is much more common in women with pendulous breasts, and is certainly predisposed to by the absence of suitable support for the breasts. It can generally be quickly cured by firm bandaging and the local application of belladonna, and its recurrence may be avoided by wearing a suitable bust bodice. In this disease cyst formation is conspicuously absent.

*Chronic Mastitis.*

Chronic interstitial mastitis, on the other hand, has an insidious onset and severe pain is generally absent; at most there is a slight aching. It is more often bilateral than subacute mastitis; it may affect more than one sector of the same breast, and I think it affects the nulliparous as frequently as the multiparous breast. It is probably closely associated with the involution of the breast accompanying the menopause, but it is often found in younger women.

Cyst formation is a very general feature of the disease, and

the cysts may be large or small, many or few, but it is the exception not to find some cysts, possibly not larger than millet seeds.

If the cysts are numerous and large there is no room for argument about treatment. The breast or breasts should be removed by simple subcutaneous amputation, the nipple and surrounding skin being preserved by carrying the incision along the outer margin of the breast, but great care is necessary to avoid leaving an ugly puckered surface when this method is used. In thin patients I have given up employing it and prefer a straightforward amputation.

*Solitary Cysts.*

But it is quite common to meet with cases where there is but one solitary cyst in the breast. My own practice in these cases is to puncture the cyst and aspirate the contents. This is quite easily done with a serum syringe and hypodermic needle, and the cyst usually collapses so completely that nothing whatever can be felt of it.

It is possible, of course, that such a solitary cyst may be the herald of a general mastitic change which will eventually in multiple cyst formation, and it is true that on a few occasions, after tapping the original cyst, I have subsequently watched the development of universal cystic disease which has required amputation of the breast. But this is certainly not the general rule, for my experience has been that most of my patients have had no further trouble, even after many years. The fluid in these cysts varies from a pale straw colour to brown or green, with perhaps cholesterol crystals floating in it, and all such cases are quite benign. But occasionally it will be found that the fluid is consistently blood-stained, and in these cases the cyst should be removed and carefully examined in case a growth has developed in its wall.

But if the case is simply chronic mastitis without obvious cyst formation, what line must be taken? Does chronic mastitis lead to cancer? Many experienced surgeons think it does. They believe it so firmly that they advise amputation of a breast so affected in order to be on the safe side, as it were. I cannot believe that the evidence is so conclusive as to lead us to offer this advice to our patients, and I strongly suspect that far too many breasts are sacrificed to this branch of prophylactic surgery. We should only allow ourselves to be guided by definite scientific evidence, and what is the evidence? It is stated that a large number of breasts removed for cancer show chronic mastitis as well, and the deduction is too readily drawn that the mastitis caused the cancer. Looked at from another point of view, one might equally well deduce that cancer causes mastitis; and in fact I believe it does—that is to say, I believe that chronic degenerative changes frequently take place in the breast tissue surrounding a malignant growth and that these changes are microscopically indistinguishable from the changes we are accustomed to describe as chronic mastitis.

From a purely pathological point of view the subject is obviously open to considerable discussion, but if we consider it from the clinical aspect the position becomes more clear.

If mastitis is indeed a common precursor of cancer, then we might expect that surgeons of experience would occasionally see patients with cancer whom they had previously treated for mastitis; or, conversely, it might be expected that some of the cases treated for mastitis would ultimately return with cancer. But it may be argued that it is scarcely likely that patients would return to the same surgeon. If this be true, then one ought to see patients with cancer who give a history of having been treated for mastitis some years previously by another surgeon. This has not been my own experience, nor, so far as I can gather, has it been the experience of those of my colleagues with whom I have discussed the question. Of all the cases of cancer of the breast that I have seen I can only find one where there was a definite history of previous mastitis. I saw this patient myself five years ago for mastitis and she returned last year with cancer. One would have expected mere coincidence to have provided more examples than this in any large group of cancer cases, apart altogether from any causal relationship. I am strongly of opinion that the bugbear of chronic mastitis as the precursor of cancer of the breast has been greatly overdone. It has even been suggested that the occurrence of mastitis resulting from intestinal stasis not only goes far to explain the frequency of cancer of the breast, but also explains its

greater frequency upon the left side owing to the fact that this particular type of mastitis appears to develop mainly in the left breast!

#### *Side Affected.*

It is certainly true that all the great collections of figures relating to cancer of the breast appear to indicate that it is more commonly met with on the left side, but the difference is less than 2 per cent. Were it not that this slight disproportion is so constantly reported by all observers, one would imagine it to be a mere coincidence; while, on the other hand, were it really due to any fundamental difference in the cancer liability of the two breasts, one would expect a much greater disproportion. I have often puzzled over this point, but it happened recently that two cases of cancer of the left breast were sent to me in quick succession, in each of which the doctor had accidentally discovered the growth while examining the heart. This must be the explanation of the discrepancy, for the vast majority of the published figures relate to operation cases, and it is, I think, reasonable to suppose that the accidental detection in this way of a small number of left-sided cases which might otherwise reach the inoperable stage without discovery fully accounts for the small apparent difference so constantly recorded. It would appear to be unnecessary, therefore, to fall back upon the left-sided mastitis of intestinal stasis—if there be any such thing—as having any very direct bearing upon the subject of cancer of the breast.

The most casual study of much recent literature relating to the breast and its diseases and minor ailments seems to indicate a fundamental lack of imagination or perspective. One is sometimes asked to believe that a trivial patch of mastitis or the presence of a minute cyst almost necessarily indicates the imminent onset of cancer. As I am not aware that such conditions are always or even generally confined to one breast, are we to be prepared to tell a patient to have both her breasts cut off merely to be on the safe side? We must preserve some sense of proportion and try to recognize that any evidence of the existence of a well defined precancerous condition in the breast recognizable by clinical or pathological methods is not yet established—whether in the shape of mastitis, cysts, or adenomata. I strongly feel that, unless or until we have unequivocal evidence to guide us, prophylactic amputation of the breast for mastitis is a thoroughly bad and unscientific proceeding.

#### *TREATMENT.*

##### *The Radical Operation.*

With regard to the radical operative treatment of cancer of the breast, I do not propose to discuss the details of the actual operation, for you all have many opportunities of seeing it performed and observing the various minor differences of incision, dissection, and technique favoured by individual surgeons; but I may say that, as one who is quite convinced of the value and importance of Handley's observations on lymphatic permeation, I endeavour to plan my operations upon this basis.

Not the least important matter is the choice of anaesthetic, and, after trying all available methods, I have come to the conclusion that for all ordinary cases ether, or a mixture of chloroform and ether, administered by some method which warms the vapour before delivery, seems to give the most satisfactory results; but in feeble patients who are bad risks owing to cardiac or respiratory complications or extreme old age I rely mainly upon local anaesthesia.

Thanks to the skill of my anaesthetists I have never yet lost a breast case from any cause whatever except, of course, recurrence of the disease.

##### *Radium and X-Ray Treatment.*

It is impossible to leave the question of the treatment of cancer of the breast without discussing the value of radium and x-ray treatment.

*Radium.*—With regard to radium there is very little to say, for the results obtained are not worth consideration. This is hardly a matter for surprise when we remember the extent of the area to be treated and the impossibility of obtaining and applying radium in sufficient quantity to influence the disease.

*X rays.*—In x rays, however, there is no question that we have a valuable means of relieving pain, encouraging hope, and prolonging life. They will in some cases promote the

shrinkage of ulcerated masses, and in others will cause the temporary or even permanent disappearance of superficial nodules. I refer now to x rays as produced by the ordinary methods in common use, and every radiological clinic possesses serial photographs showing unmistakable evidence of the value of this form of x-ray treatment in cases of breast cancer.

#### *Deep Therapy.*

During the last two years a new technique has been evolved in Germany dependent upon the use of much more powerful apparatus, which is actuated by much higher voltages and emits a much harder and therefore much more penetrating x ray. It was hoped—indeed it was widely claimed—that this harder type of ray when delivered to the diseased part in appropriate quantities would destroy the cancer cells in their nests, as it were, with no—or at any rate no serious—injury to the surrounding healthy tissues.

As soon as the opportunity offered I arranged to give the method a trial, and about six months ago three cases of recurrent cancer of the breast were carefully selected. They were treated with the latest apparatus under the best obtainable conditions by a radiologist of the greatest ability. In each case the so-called full cancer dose of three hours or so was given, and now at the expiration of six months these are the results:

Case 1 feels better, but numerous skin nodules have appeared in the treated area. There is no improvement in the other local manifestations of the disease.

Case 2 felt strong and well until the treatment, but has suffered intolerable pain ever since it was applied. There is no improvement in the local condition, which in general has progressed except for the shrinkage of a small subcutaneous nodule.

Case 3 is unchanged except for the development of a suspicious nodule in the skin of the treated area.

These cases were done six months ago, and in those days—for events move quickly in the x-ray world—it was hoped that one exposure of three hours or so would suffice. The most that I hear claimed by my radiological friends to-day is that, given early cases of breast cancer free from metastatic growth, good results may be expected from repeated treatment—which is somewhat where we were before Erlangen.

I should like to emphasize the fact that it is only with regard to cancer of the breast that I am expressing my opinions, for my personal knowledge and experience of the results obtained in cancer of other organs is insufficient to form a judgement.

We have had our apparatus at the Cancer Hospital in full work for a few months only, and the tendency has been to use repeated moderate doses spread over an appreciable period of time rather than massive doses administered at a single sitting. However, we ought soon to be in a position to form a definite opinion, and we may find that it is only in certain kinds of cancer that useful results are to be expected from deep therapy. If there is any real analogy between x rays and radium, my experience with the latter would certainly tend to support such a view.

As I have already stated, I think radium useless in carcinoma of the breast, and the same applies to many other forms of cancer; but in certain situations, notably the cervix uteri, it is undoubtedly of the greatest value. Moreover, I find that I am improving my results in the cervix and elsewhere by using smaller quantities of radium but for very much longer periods, the tubes or needles being buried in the growth for days or weeks at a time. But even then there is no regularity in the reaction.

Recent pathological research appears to indicate so strongly a separate specific cause for each form of cancer that it is conceivable that further investigation may suggest the possibility of each form of cancer requiring its own specific remedy and perhaps its own specific wave-length—who knows? It is just possible that we may after all discover that x-ray technique has been developing in the wrong direction, and that the radiologist who is constantly striving after a harder and more penetrating ray is not very different from the surgeon who endeavours to improve his results by employing a longer, a stronger, and a sharper knife.

Finally, let me say that, if I have unwittingly underrated any man's achievements in the field of x-ray therapy, you as members of the Fellowship of Medicine—to whom all doors are open—should have abundant opportunities of correcting my estimate of the present position of deep therapy in the treatment of cancer of the breast.

## BLOOD TRANSFUSION.\*

BY

E. F. SKINNER, M.A., M.B., F.R.C.P.,  
ASSISTANT PHYSICIAN, SHEFFIELD ROYAL HOSPITAL.

THE most obvious indication for blood transfusion is previous loss of blood, and the present revival of the operation is due largely to the brilliant results following this procedure in battle casualties. The shock condition produced by severe haemorrhage is due to two factors: (1) Loss of oxygen carriers, and (2) loss of blood volume; but whereas the latter can be quickly made good by the tissues pouring out fluid, except in those cases where the tissues themselves are drained of their fluids to such an extent that there is none left to replace blood loss, the former is only made good very slowly, and whilst by the injection of suitable solutions into the circulation the deficiency in blood volume can be replaced, the only means of replacing oxygen-carrying capacity is by means of blood transfusion.

Haemorrhages, whether sudden and severe, as in injuries and obstetric cases, or long-continued slight bleedings, equally benefit by transfusion, whilst the clinical anaemias, whether primary or secondary, are improved, and though in the case of the primary anaemias no permanent cure may yet be recorded, almost every observer has been struck with the occurrence of dramatic recoveries. But besides these conditions there are many others where blood transfusion may be of great value—for instance, in seriously ill persons before an obligatory operation the administration of 200 or 300 c.cm. of blood might entirely alter any possible end-result of surgical interference<sup>1</sup>; the terrible mortality of influenza and pneumonia<sup>2</sup> occurring in epidemic form might be lessened, and a number of successful cases have been recently reported from France. In the blood diseases—haemophilia, purpura haemorrhagica, and the like—there is again an obvious indication for blood transfusion, and Graham,<sup>3</sup> in a paper read before the Edinburgh Medico-Chirurgical Society, reported a series of 75 blood transfusions, amongst which were a number of instances of these conditions. Blair Bell<sup>4</sup> advocates its use in eclampsia, whilst Ramsay<sup>5</sup> refers to its gratifying employment in cases of acute nephritis. The employment of transfusion in septicæmic cases is advocated by some authors but deprecated by others, and Lewisholm<sup>6</sup> utters a warning against its routine use in septicæmia, but reports good results in staphylococcal osteomyelitis.

When such a varied list of diseased conditions is studied it is clear that the action of the blood is not the same in each case: that whereas in haemorrhage and anaemia probably the increased oxygen capacity of the circulating fluid is responsible for the benefit, this cannot apply to osteomyelitis, and in this type of case the possibility of "complement" or "antibody" transference must not be lost sight of.

The catastrophes that from time to time were observed to follow the intravenous administration of blood remained unexplained until it was discovered by Landsteiner<sup>7</sup> that when the blood serum of one individual was brought into contact with blood corpuscles from another individual there sometimes occurred a clumping of the corpuscles, with the formation of little conglomerate masses quite easily visible to the naked eye, and at once it was realized that in this phenomenon lay the explanation of these catastrophes—in other words, that there is an incompatibility of bloods of certain individuals, and that two such incompatibles cannot act as "donor" and "recipient" respectively in a transfusion operation, whence it follows that before each such operation the compatibility of the two bloods must be determined.

## Compatibility of Blood.

In 1901 Landsteiner examined a large number of blood serums from the point of view of their property of agglutinating red blood cells, and as a result of his observations he stated that human beings could be divided into three classes according to the agglutinin content of their blood; these classes he called A, B, and C, in which the serum of Class A agglutinated the corpuscles of Class B, the serum of Class B agglutinated the corpuscles of Class A, whilst the serum of Class C agglutinated the corpuscles of both A and B classes (Fig. 1).

Moss<sup>8</sup> in 1910 repeated this work, but found that the groups were insufficient to cover all cases of agglutination; that if in a large number of different bloods the serum of each was mixed with the corpuscles of every other there were

SERUM	CORPUSCLES

Fig. 2.—Moss's 4 group classification.

certain exceptions to Landsteiner's grouping, and he found that a four-class grouping was necessary to cover all cases which groups he called I, II, III, and IV—a classification which is still adhered to for convenience and which is shown in Fig. 2.

Moss assumed the possession by the blood corpuscles of his groups of three different agglutinogens, each reacting with a specific agglutinin in the serum of another group, but this explanation is now simplified by an adaptation of Landsteiner's original conception worked out by von Dungern and Hirschfeld.<sup>9</sup>

This view is now known as Landsteiner's law of iso-agglutinins, and it sets forth that there are present in human blood two agglutinable substances, A and B, which react with specific agglutinins *a* and *b*, and that if any one blood contains an agglutinable substance it will contain the agglutinin which reacts with the alternative agglutinable substance; thus a blood which contains A agglutinable substance will contain the *b* agglutinin and vice versa. By the variation of these factors in the blood the four classes are determined and the supposed arrangement may be shown diagrammatically as in Fig. 3.

Group II.	Group III.	Group IV.	Group I.

Fig. 3.—Landsteiner's law of iso-agglutinins (after Hirschfeld).

In the figure the English and American numerical groups are indicated and it will be seen that Group II possesses the agglutinable substance A and agglutinin *b*, Group III the agglutinable substance B and agglutinin *a*, whilst Group IV has both agglutinins but no agglutinable substance, and Group I has both agglutinable substances A and B but neither agglutinin. Therefore Landsteiner's law may be shortly stated thus: "In any blood there are always present agglutinins against the agglutinable substance absent from the same blood."

It is stated that shortly after birth<sup>10</sup> the blood takes up the characters of one of the four groups, and these apparently persist throughout life unchanged. In a personal investigation of this point I have found that at the moment of birth the child's blood may possess an agglutinable substance quite different from that of the mother's blood. Out of 17 such cases investigated this year, in 11 cases the blood of the child contained the same agglutinogens as the blood of the mother, whilst in 6 cases they were different.

## Technique of Agglutination Tests.

The compatibility of any two bloods is shown by the non-appearance of agglutination when the serum of each is mixed with the corpuscles of the other, and by referring again to Moss's table (Fig. 2) it will be seen that by means of the serums of Groups II and III all samples of blood can be grouped according to their agglutinating properties: thus if a sample of blood is mixed with a little serum from a Group II blood and also with serum from a Group III blood, and agglutination occurs in both mixtures, the drop of blood comes from a Group I individual; if, on the other hand, no agglutination occurs in either mixture, then the blood being tested belongs to Group IV; if agglutination occurs with serum II the blood belongs to Group III, and if agglutination takes place in the serum III the blood under investigation is a Group II. With samples of serum from known Groups II and III it is possible to test out quickly any blood, and before a transfusion operation this must always be done. It is found that it is sufficient for practical purposes that the corpuscles of the blood from the donor should not be agglutinated by

\* A Post-graduate Lecture delivered before the Chesterfield Division of the British Medical Association. April 7th, 1922.

the recipient's serum, for though theoretically the donor's serum may agglutinate the recipient's corpuscles this serum is so largely diluted that this does not prove any great danger and need not be considered.

Since the corpuscles of Group IV are agglutinated by no serum of any other group, the members of this group are spoken of as "universal donors," and generally such a Group IV blood is chosen for transfusion purposes if possible.

The testing out of the compatibility or otherwise of bloods is extremely simple, and can be done at the bedside. There are many ways of carrying out the test, but the simplest, and at the same time most reliable, is as follows:

Into a small test tube such as is used for the Wassermann reaction is placed a small quantity of N/10 sodium citrate in normal saline, and four or five large drops of blood, obtained by pricking the finger, are mixed with this citrate solution, giving an emulsion of r.d. blood corpuscles. On to one end of a microscope slide is placed a drop of serum from a Group II blood, and on to the other end of the slide a drop of Group III serum, to each of which is then added a little of the corpuscle emulsion, each mixture being stirred with a smooth glass rod and the slide gently rocked to and fro. If agglutination occurs, it is quickly and unmistakably visible to the naked eye, and appears as a fine deposit resembling brick-dust, the particles of which often gradually get larger and larger as more and more corpuscles are agglutinated, until in some cases there appear a few deep crimson dots floating in clear serum.

Before any blood is used for transfusion it is essential to exclude the possibility of conveying any blood-borne disease, so that a Wassermann reaction should be carried out to exclude syphilis, and a careful history of all previous illnesses obtained; donors should be healthy adult males between the ages of 30 and 40 if possible, and during the next decade the possibility of conveying blood parasites should be kept in mind, in view of the large number of adult men who have been abroad during the war and contracted various tropical diseases—for example, malaria, filariasis, etc. Syphilis is said to have been conveyed by blood transfusion.<sup>10</sup> The previous occurrence in an individual of such conditions as acute rheumatism, trench fever, pneumonia, cerebro-spinal fever, typhoid, etc., should prevent such individual acting as a blood donor from the point of view of danger to the recipient, whilst albuminuria, even though transient, any cardiac debility, or marked obesity in a prospective donor should negative his employment on account of danger to himself.

#### Technique of Transfusion.

When a suitable blood donor has been obtained the actual operation of transfusion presents little difficulty, at any rate if the "citrate method" is employed, and as this method has the outstanding merit of being a "one-man" procedure, whereas the other methods, whether Kimpton's paraffin tube or any of the syringe methods, require skilled surgical team work, it will be the only one described here.

The apparatus required is a large wide-necked bottle capable of holding 700 to 800 c.cm., graduated in 50 c.cm., and provided with a rubber cork with three holes through which pass three glass tubes, the middle one of which is ground and tapered to fit the stem of a small separator funnel. To one of the side glass tubes, A, a length

FIG. 4.

of rubber tubing of about 18 inches is attached carrying at its other end a needle with a fairly wide bore (from 1 to 1.5 mm.), whilst to the other side tube, B, is attached a double action bulb giving either a negative or positive pressure. On the centre tube, C, fits the special funnel, which has a capacity of 30 c.cm., and marked on the glass at the half-way or 15 c.cm. level, and provided with a stopcock, E. The apparatus is shown in sketch form in Fig. 4.

After sterilizing the whole apparatus blood is obtained from the donor in the following way. A solution of sodium citrate (3.5 per cent.) is poured into the bottle and allowed to run out through the

needle by simply inverting the bottle, the other tubes being meanwhile stopped by means of short pieces of rubber tube clipped by "bulldog" artery forceps, and after the tube A has been thoroughly flushed the bottle is turned over again, leaving 15 c.cm. of citrate solution in the bottom. The funnel is next placed on the centre glass tube and filled with citrate solution up to the 30 c.cm. mark, the stopcock E being shut and the suction bulb attached to the other glass tube B, the tube A being clipped. The bottle is exhausted to a mild degree and the whole apparatus is ready for use.

The donor, lying down on a bed or table, has the arm cleansed and swabbed with iodine or picric acid, and after the antecubital veins have been rendered prominent by means of a tourniquet, or arm band, the needle is pushed directly into the vein, preferably in a distal direction, though this point is not of much importance, and the tube clip removed. Blood immediately flows into the bottle, and as soon as the 100 c.cm. mark has been reached the tap on the citrate funnel is turned and a further 15 c.cm. allowed to run in, the funnel being again filled up to the 50 c.cm. mark, and as each 50 c.cm. of blood runs into the bottle 15 c.cm. of citrate is allowed to pass in from the funnel. This is better than putting a large bulk of citrate into the bottle first, as one may not always obtain the total quantity of blood counted on. When the blood has been collected and thoroughly mixed with the citrate (the bottle should be kept constantly agitated whilst the collection is proceeding, being also warmed by standing in water at 100° F.), the funnel is detached and a small length of rubber tubing, suitably clipped, is substituted. The suction bulb is replaced by a small piece of tubing and clip, and a somewhat finer needle is substituted for the collecting needle.

The recipient is similarly prepared as to the arm, and generally it is unnecessary to dissect out a vein, though at times in very

collapsed patients this has to be done, so that it is always advisable to have at hand a little local anesthetic, hypodermic syringe, scalpel, forceps, ligatures, etc. The bottle of blood is inverted and a little of the contents allowed to run out of the needle, which is then clipped off, whilst the clip on the middle tube is released to allow air to pass up into the bottle. The needle is then pushed into the recipient's vein, in the proximal direction, and the citrated blood allowed to run in slowly. Gravity is, as a rule, quite sufficient for the purpose, but occasionally a little positive pressure must be exerted, in which case the pressure bulb is attached to the centre tube, and if positive pressure is being used it is as well to have the cork fastened down, as otherwise it will be forced out. In Fig. 5 the bottle is shown in position for the gravitational giving of citrated blood.

The actual amount of blood to be transfused at any one time will depend upon a variety of circumstances, and at present this aspect must be left to the discretion of the operator, as no unanimity has been reached, nor does the amount of citrate solution, within reason, seem to matter practically. This, however, is a point on which further light might be thrown with advantage, as I have seen one case in which unexpected symptoms developed during a transfusion within a few seconds of the blood beginning to flow, symptoms which were repeated four times as, for various reasons, four successive veins were punctured; and it was not until the following day that it was discovered that, owing to a clerical error, the citrate solution was being used in a strength of 30 per cent. instead of just over 3 per cent. The strength of the citrate solution when mixed with the blood in the way described above gives a resulting mixture of about 1 per cent. sodium citrate, and the time taken to infuse 500 c.cm., which may be looked upon as an average amount of citrated blood, should be from fifteen to twenty minutes, a slow transfusion being less liable to produce reactions and symptoms than a rapid one.

The actual amount of blood to be transfused at any one time will depend upon a variety of circumstances, and at present this aspect must be left to the discretion of the operator, as no unanimity has been reached, nor does the amount of citrate solution, within reason, seem to matter practically. This, however, is a point on which further light might be thrown with advantage, as I have seen one case in which unexpected symptoms developed during a transfusion within a few seconds of the blood beginning to flow, symptoms which were repeated four times as, for various reasons, four successive veins were punctured; and it was not until the following day that it was discovered that, owing to a clerical error, the citrate solution was being used in a strength of 30 per cent. instead of just over 3 per cent. The strength of the citrate solution when mixed with the blood in the way described above gives a resulting mixture of about 1 per cent. sodium citrate, and the time taken to infuse 500 c.cm., which may be looked upon as an average amount of citrated blood, should be from fifteen to twenty minutes, a slow transfusion being less liable to produce reactions and symptoms than a rapid one.

#### Reactions.

Certain reactions, however, do occur, and even in carefully tested bloods, where the agglutinin contents seem quite compatible, there is a slight risk which has been stated to be as high as 1 per cent.—a risk at present unexplained. If a reaction occurs it generally manifests itself during the actual operation, the recipient complaining of pain in the chest and difficulty of breathing, which may be accompanied by nausea or vomiting and sometimes the appearance of an urticarial rash and even loss of consciousness, but generally only the first stage of this reaction is seen and if the transfusion is stopped for a few moments and then allowed to proceed more slowly no more trouble is encountered.

Quite frequently, some thirty or forty minutes after the operation there is a "late" reaction, ushered in by a shiver or rigor, which may be slight or severe, accompanied by a mild pyrexia up to 100° F., lasting perhaps for twelve hours, and

\* Messrs. Allen and Hanbury have made a very convenient outfit for me on these lines.

symptoms are more likely to occur if the operation is hurried; the more quietly everything is done and the fewer the number of persons present the better will it be tolerated; at present the method is looked upon as somewhat of a therapeutic curiosity and tends to attract too much attention.

#### Results.

It is as yet difficult to estimate the value of blood transfusion apart from its use in haemorrhagic shock, where its value is incontrovertible, since it is only too frequently resorted to as a last desperate hope. If it is to be of real assistance it must be used much more frequently and early, for its final value will not depend on the cases of gastric ulcer snatched from death, nor the occasional miraculous recovery of the pernicious anaemia patient, but rather on a sound understanding of its rationale and method of action, and such can only be discovered by frequent observations in large numbers of varying conditions. In those conditions where unknown metabolic processes are at work—for example, haemophilia, purpura haemorrhagica, haemorrhagic necrosis, etc.—much might be learned both of the value of blood transfusion, and even of the underlying factors of these pathological conditions, by carefully carried out observations; and, again, its rôle in such chronic infections as tuberculosis might be found to be not entirely useless.

## THE COMPOSITION OF THE GASES IN ARTIFICIAL PNEUMOTHORAX.

BY

LEONARD HILL, M.B., F.R.S.,

AND

J. ARGYLL CAMPBELL, M.D., D.Sc. EDIN.

(From the National Institute for Medical Research, Hampstead.)

ON several occasions during the past year we have had the opportunity to obtain samples of gas from the thoracic cavity in patients with artificial pneumothorax. As our interest was thereby stimulated we carried out several experiments in which we produced artificial pneumothorax in animals—cats, rabbits, and a goat. We studied the composition of the air in the thoracic cavity, using Haldane's apparatus for the analysis of oxygen and carbonic acid. Our observations, although fairly numerous, form but a small contribution to the total, since the previous researches on this subject are extensive. We have made a study of the previous literature and consider that a critical review will be useful, seeing that the conclusions reached by different observers were so varied. As we are at present carrying out a research on the changes in composition of air injected into other body cavities and tissue spaces, and obtaining thereby rather striking results, we feel we are perhaps fortunately placed for a review of the afore-mentioned subject, and attempt herein to bring the different results, previously obtained, into line.

A very early research was that of Davy,<sup>1</sup> who in 1823 studied the gases in a case of pneumothorax. He obtained some of the gas from the thoracic cavity after the death of the patient. It was found that air had passed freely from the lung into the pleural cavity through a valvular ulcerated opening in the upper part of the superior lobe; the valvular opening prevented the air escaping again. Davy found 8 per cent. of carbon dioxide and 92 per cent. of nitrogen in the gas. He carried out numerous experiments on animals, injecting various gases and mixtures of gases—air and carbon dioxide, hydrogen and carbon dioxide, hydrogen and nitrous oxide gas. In the light of modern research, the older observers appear to have been much handicapped as regards the accuracy of their results owing to crude analytical methods. It seems hardly fair, then, to criticize their pioneer work.

Many important researches have been published in modern times. In 1914 Webb, Gilbert, James, and Havens<sup>2</sup> made extensive series of observations, mainly with the object of determining from a clinical point of view the best gas to inject to produce artificial pneumothorax, and concluded that, as Haldane had predicted, little, if any, clinical advantage was

gained by the employment of nitrogen rather than atmospheric air for the production of artificial pneumothorax. Although they did not pay any great attention to or discuss fully the reasons for the changes in the composition of the injected gases, they gave very complete details of the analyses after the injection of oxygen, nitrogen, and air. Their figures for carbon dioxide in the imprisoned gas after many hours varied between 2.64 and 13.59 per cent., and the figures for oxygen varied between 0.41 and 8.66 per cent., except when pure oxygen was the gas injected into the thorax, the figures for oxygen percentage after forty-eight hours being then as high as 24.04 per cent. The remaining percentage, and therefore much the highest percentage, was made up by nitrogen. To quote these authors:

"The oxygen cases are especially noteworthy from the discovery of the large addition of nitrogen which must have diffused into the pleural space. Since blood contains only a small percentage of nitrogen (about 2.4 per cent.), diffusion must take place between alveolar air and pleural space to establish equilibrium. It would, therefore, seem certain that, whatever gas is used for the production of pneumothorax, it does not long remain pure; for Nature rapidly changes it until an analysis yields the equivalent of alveolar air. At our elevation (6,000 feet) alveolar air averages carbon dioxide 6 per cent., oxygen 14 per cent., and nitrogen 80 per cent.

"In general the longer the time between injections the higher the percentage of carbon dioxide and the lower the percentage of oxygen, the former tending to reach 10 per cent., and the latter 1 per cent. to zero."

The second paragraph just quoted contradicts the first paragraph as far as the oxygen is concerned. The first paragraph says the oxygen should be the same as in the alveolar air—that is, 14 per cent.—whereas the second paragraph states that the oxygen tends to reach from 1 per cent. to zero. It is quite obvious that their explanations are not sufficient to cover the variations given in their tables. They carried out an experiment under strictly physiological conditions with two monkeys. The right lungs of two monkeys of equal size and weight were collapsed under ether, one with 125 c.cm. of air and the other with the same amount of nitrogen. Forty-eight hours after positive pressure had been induced in this way the amount of gas still present in the monkey injected with air was 83 c.cm., and on analysis it gave carbon dioxide 8.06, oxygen 4.24, and nitrogen 87.70; whereas the amount of gas still present in the monkey injected with nitrogen was 92 c.cm., and on analysis it gave carbon dioxide 8.52, oxygen 5.61, and nitrogen 85.87. The figures show slight variation, but no conclusion may be drawn from them unless it was known that the lung in each monkey was collapsed to the same extent, or in other words that the circulation was similarly altered in both. These observers appear to have left the gases in the blood out of consideration, but, as has already been stated, the composition of the gases was not their main theme.

The blood gases have been very fully considered by Rist and Strohl<sup>3</sup> in their conclusions. They made a very careful physical study of the volume changes of the gases and of the changes in absolute quantities of the gases in the thoracic cavity following the injection of air, nitrogen, oxygen, and carbon dioxide. They represented these changes by means of graphs showing the variations in quantities and also in partial pressure at definite intervals after the operation for gas. They concluded that several days after the operation for artificial pneumothorax—not complicated by purulent exudate—analysis of the gases contained in the pleural cavity proves that the composition of the gases is the same in all cases. The phenomena which occur after the injection of gas into the pleural cavity, according to these observers, are explained completely by the exchange of gases which takes place in the living body, and which consist of a diffusion through the pleural membrane with rapidity proportional to the coefficient for each gas, and depending on the partial pressure of each gas on each side of the membrane. Equilibrium, they state, is established between the gases of the pleural cavity and the venous blood, and they hold that their graphs show why different results have been obtained at different places before the establishment of this equilibrium. It is well known that carbon dioxide diffuses twenty-five times more rapidly through tissues than does oxygen, and obviously allowance must be made for this and similar physical laws. Rist and Strohl found that after the injection of nitrogen and oxygen the total quantity of gas was increased for a short period, probably owing to the rapid diffusion of over-compressed gas out of the blood; thus is the phenomenon of over-compression explained. Some of our own experiments illustrate very clearly how rapidly the percentage of carbon dioxide rises in

air injected into the thoracic cavity. It was demonstrated in one of Dr. Olive Riviere's patients. He kindly allowed us to withdraw two samples immediately after he had produced artificial pneumothorax with air containing 0.03 per cent. of carbon dioxide. On July 14th, 1922, at 2.59 p.m. 100 c.cm. of air were injected slowly into the thoracic cavity of a boy; at 3.4 p.m. a sample was withdrawn which now contained 0.8 per cent. of carbon dioxide. From 3.5 p.m. to 3.11 another 300 c.cm. of air were injected; at 3.12 p.m. a sample was withdrawn which contained 1.93 per cent. of carbon dioxide (see Table IIb). Grass' obtained similar results.

TABLE I.  
March 27th, 1922. Cat: Urethane.

Time.	Conditions.	Percentage Composition of Air in Thoracic Cavity.	
		CO <sub>2</sub> .	O <sub>2</sub> .
12.50	20 c.cm. of air injected*	—	—
12.53	Sample withdrawn	4.50	19.70
12.54	10 c.cm. of air injected	—	—
2.1	Sample withdrawn	6.10	15.60

\* The composition of the air injected in all cases was approximately 79.93 per cent. oxygen, 0.03 per cent. carbon dioxide, and 79.04 per cent. nitrogen.

We injected 20 c.cm. of pure air containing 0.03 per cent. of carbon dioxide and 20.93 per cent. of oxygen into the thoracic cavity of an urethanized cat (see Table I) and found that after three minutes the percentage of carbon dioxide had risen to 4.50, whilst the percentage of oxygen had fallen only about 1 per cent. In the case of a goat the carbon dioxide rose from 0.03 to 3.56 per cent. in less than eight minutes after the injection of 300 c.cm. of air under local anaesthesia (see Table IIa). We are indebted to our colleague Dr. L. Colebrook for carrying out this operation. The oxygen in this experiment fell only about 1 per cent. in the same time.

3.12	Sample withdrawn	1.93

Rist and Strohl were justified in excluding cases of pneumothorax attended by purulent exudate. It has long been known that the carbon dioxide percentage rises very high, as much as 11.5 per cent., in pathological fluids. Grass' found that in pneumothorax accompanied by exudate the carbon dioxide percentage was as high as 13.62, whereas in dry pneumothorax it averaged about 6. Pathological processes probably explain some of the high figures for carbon dioxide recorded in gases in pneumothorax. It must also be remembered that in physiological conditions the urine and the bile sometimes contain from 7 to 9 per cent. of carbon dioxide (Strassburg<sup>2</sup>); therefore it is reasonable to conclude that in the tissues where these secretions had formed the percentages must be about the same. Very recently Dunn and Thompson<sup>3</sup> pointed out that 9 per cent. of carbon dioxide must be recognized as a normal figure for the gases in the

stomach. It might be expected, therefore, that the venous blood would sometimes normally contain a fairly high percentage; thus high percentages might be present in cases of pneumothorax, if Rist and Strohl are correct in their conclusion that the composition of the gases in the thoracic cavity depends on the gases in the venous blood. Recently, however, Rist and Strohl's work has been criticized by Dantrebaude and Spehl,<sup>4</sup> who conclude that it is more correct to state that the carbon dioxide percentage in the thoracic cavity depends on the carbon dioxide present in the blood bathing the compressed lung, the blood of which is richer in the carbon dioxide than is the blood in the normal lung, because the compression slows the circulation. They also point out that Rist and Strohl used inaccurate figures for the volumes of gases in normal blood.

Another factor which must be taken into account is whether the pneumothorax is open—that is, whether there is a communication with the outside air or with the air in the lung by means of which air can pass freely into the thoracic cavity. Grass and Meiners<sup>5</sup> point out that this can easily be determined by analysing a sample of gas from the pneumothorax and then drawing out more gas; if there is an opening, fresh air will enter the thoracic cavity as the gas is being removed and the fresh air will thus lower the carbon dioxide percentage in the pneumothorax gas. Undoubtedly such a leakage may explain the very low figures for carbon dioxide given by some observers as being present in cases of pneumothorax.

At this stage we may sum up the position as regards carbon dioxide in the gases of pneumothorax as follows: The carbon dioxide percentage in the thoracic cavity comes into equilibrium fairly rapidly with the carbon dioxide in the blood bathing the compressed lung, unless pathological processes in the tissues of the lung or pleura cause a local increase—or perhaps occasionally decrease—of carbon dioxide; and unless there is a leakage of air into the cavity which will lower the percentage of carbon dioxide.

We consider that the equilibrium is established very rapidly between the injected air and the blood as regards the carbon dioxide. Of course the greater the quantity of air injected the longer the interval before the equilibrium will be established, but even at the latest a couple of hours should be the limit. Henderson and Haggard<sup>6</sup> have shown that after injecting 2 litres of air into the abdominal cavity of a dog equilibrium as regards carbon dioxide content was established in an hour and three quarters. Our own results with gases in the stomach, intestine, bladder, in the thoracic and abdominal cavities, and under the skin (see Table III, A and B) gave very similar results, so that there is no reason to

TABLE IIIa.  
Cat: No anaesthetic.

doubt that equilibrium is established very rapidly in the thoracic cavity—that is, of course, unless the tissues have become much thickened by pathological processes; but an extensive general thickening would be somewhat rare. It has been found that fat renders the diffusion of carbon dioxide slower, owing to low solubility of this gas in fat.

As regards the oxygen percentage in the gas of pneumothorax it is obvious that any leakage in the cavity will raise the percentage, owing to the entrance of air. In view of recent physiological research it seems that, if the gases are left undisturbed in the thoracic cavity, the oxygen percentage falls very slowly and finally becomes very much lower than that of the blood bathing the lung. It probably corresponds finally with the oxygen percentage in the surrounding tissue. In physiological experiments on monkeys Webb and his co-workers<sup>3</sup> obtained fairly low figures for oxygen percentage three days after the last injection of air and nitrogen, the percentages being 4.85 and 3.57 respectively; these figures probably represent the oxygen percentage of the surrounding tissues. They seem much too low for oxygen percentage in the blood of such monkeys. Henderson and Haggard<sup>9</sup> obtained low figures (about 6 per cent.) for oxygen in gas in the abdominal cavity; nevertheless the percentages they found were much higher than those—1 per cent. and less—given by Edkins<sup>10</sup> for oxygen in the stomach cavity.

Our own figures for oxygen percentage in gas in the abdominal cavity of normal animals resemble those of Henderson and Haggard.

Thus on November 3rd, 1922, at 12.30 p.m., 250 c.cm. of air were injected into the abdominal cavity of a rabbit (see Table IV); at

TABLE IV.  
Rabbit: Urethane.

Date.	Time.	Conditions.	Percentage Composition of Air in Abdominal Cavity.	
			CO <sub>2</sub> .	O <sub>2</sub> .
1922. Nov. 3	12.20 p.m.	250 c.cm. air injected	—	—
	3.10	Sample withdrawn	4.67	15.66
Nov. 6	12.10 p.m.	Sample withdrawn	7.01	5.00
Nov. 7	11.50 a.m.	Sample withdrawn	6.42	5.31

3.10 p.m. on the same day the oxygen percentage was 15.66. On November 6th, at 12.10 p.m., the same gas being in the abdominal cavity, the percentage was 5.00, and on November 7th, at 11.50 a.m., the oxygen percentage was 5.31. We also obtained low oxygen percentages in air that had been under the skin of normal animals for some days. Thus air containing 20.93 per cent. oxygen was injected under the skin on February 2nd, 1923, at 5 p.m.; on February 5th, at 1 p.m., the percentage of oxygen was found to have fallen to 3.50 (see Table V).

TABLE V.  
Rabbit: No anaesthetic.

Date.	Time.	Conditions.	Percentage Composition of Air under the Skin.	
			CO <sub>2</sub> .	O <sub>2</sub> .
1923. Feb. 2	5 p.m.	Air injected under skin	—	—
		Sample withdrawn	8.23	3.50
Feb. 5	1 p.m.	Sample withdrawn	—	—
Feb. 7	4.40 p.m.	Air injected under skin	—	—
Feb. 9	2.30 p.m.	—	8.13	3.55

It is possible that the oxygen tension varies somewhat in different tissues and also at different times in the same tissue. Very low figures, resembling those (1 per cent.) of Edkins for the stomach cavity, have been obtained in the gases in pneumothorax, so that in these cases the oxygen percentage in the surrounding tissue may have been the same. Pathological changes in the lungs and pleura, such as thickenings, would probably lower the oxygen percentage in these tissues.

TABLE VI.  
Dr. Pask's patient.

Time.	Conditions.	Percentage Composition of Air in Thoracic Cavity.	
		CO <sub>2</sub> .	O <sub>2</sub> .
Hours. 0	450 c.cm. oxygen injected into left pleural cavity	—	—
48	Sample withdrawn	4.90	15.34

as would also the presence of pathological exudates. Grass<sup>4</sup> found the percentage of oxygen to be about 1 in cases with exudate, whereas it averaged 4 in cases of dry pneumothorax. Previous results, particularly those of Webb and his co-workers<sup>3</sup> and of Rist and Strohl,<sup>5</sup> and our own results, prove

that any oxygen injected was very slowly absorbed by the tissues compared with the rate with which carbon dioxide diffused out from the tissues. Dr. Pask of High Carley Ulverston, kindly allowed us to examine a sample of gas from the thoracic cavity of one of his patients. Two days after the injection of 450 c.cm. of pure oxygen the percentage of oxygen present in the cavity was still about 15 (see Table VI). Similar figures were obtained from patients by Webb and his co-workers.<sup>3</sup>

#### Summary.

1. The carbon dioxide percentage in the gases of pneumothorax appears to approximate very rapidly to that of the blood bathing the compressed lung. The volume of gas introduced in carrying out artificial pneumothorax may thus be increased at first, but not more than about 6 per cent.

2. The oxygen percentage in the gases of the pneumothorax cavity approximates very slowly to that in the tissues bounding the cavity. As nitrogen diffuses out equally, it makes little difference whether oxygen or air be used for inducing artificial pneumothorax.

3. Pathological fluids and tissues usually cause abnormally high percentages of carbon dioxide. Pathological changes probably lower the oxygen content.

4. Any leakage in the thoracic cavity lowers the carbon dioxide percentage, but increases the oxygen percentage in the imprisoned gas.

## STERILIZATION OF THE UNFIT.\*

BY

R. A. GIBBONS, M.D., F.R.C.S. EDIN.,

GENAECOLOGIST TO THE GROSVENOR HOSPITAL FOR WOMEN.

If in this country the revolutionary suggestion be advanced of sterilizing the mentally defective children and preventing the marriage of those with mental weakness, or those having such a strong family history of insanity as to make it certain that idiots or mentally unfit offspring would result, it is quite evident that strong arguments in its favour must be adduced before legislation could be hoped for.

#### The Increase of Insanity.

On January 1st, 1922, the number of notified insane persons under care in England and Wales was 123,714, an increase of 3,370 on the number on January 1st, 1921. This increase followed one of 3,580 in 1920, and may be compared with the average annual increase of 2,251 for the ten years ending December 31st, 1914—the decade immediately preceding the war.<sup>1</sup> The mentally defective persons under care on January 1st, 1922, numbered 13,810 (males 6,326, females 7,484). Compared with the same date in the year previous this was a net increase of 1,784 patients.<sup>1</sup>

In Scotland on January 1st, 1922, exclusive of insane persons maintained at home by their natural guardians, there were 18,027 insane persons of whom there was official cognizance, including the inmates of training schools for imbecile children, who have not been certified under the Mental Deficiency Act, and of the Criminal Lunatic Department of Perth Prison.<sup>2</sup> The increase over the previous year was 221.

In Ireland on December 31st, 1919, there were 22,578 insane in various district, auxiliary, private asylums and mental hospitals; so that in Great Britain and Ireland there were at the dates mentioned no fewer than 178,129 affected.<sup>3</sup> They does not include all those cases affected mentally who are in sufficiently good circumstances to obviate the necessity of entering a public institution.

As the foregoing shows that there is an annual increase in these numbers, it is clear that there is urgent need to do all in our power to ameliorate this state of affairs. It has been estimated by an eminent authority that there are at present in the United States of America<sup>4</sup> 42 institutions for the feeble-minded, 350 hospitals for the insane.

\* Read before the Westminster and Holborn Division of the British Medical Association on April 12th, 1923. The discussion is reported at page 760.

23,000 juvenile delinquent institutions, 100,000 criminals, and 300,000 insane and feeble-minded.

This same authority estimates that two-thirds of these defective individuals are parents of defective children; this is evidence of the enormous importance of heredity and family history.

#### *Heredity.*

Heredity has been defined by Professor Thomson as "The genetic relation between successive generations."<sup>5</sup> Look defines it as "The transference of similar characters from one generation of organisms to another, a process effected by means of the germ cells, or gametes."<sup>6</sup>

The hereditary substance represented by the sexual pronuclei which fuse together in the act of fertilization Nägeli calls by the name of idioplasm.<sup>7</sup> The resulting germ contains the images of two persons, and is therefore capable of transmitting by heredity their characteristics to the individual developed from it. In Mendel's experiments with the pea he called the character that prevailed *dominant*, and the character that was suppressed *recessive*. He found that a cross between a plant with a dominant character and a plant with a recessive character yielded offspring all resembling the dominant parent as regards the character in question. In the next generation the cross-bred plants were allowed to fertilize themselves, with the result that their offspring exhibited the two original forms, in the proportion on the average of three dominants to one recessive. When the recessives were allowed to fertilize themselves, they gave rise to recessives only for any number of generations.<sup>8</sup> Mendel's interpretation of the important set of facts he discovered was expressed in the theory of gametic segregation:

"The essential part of the discovery is the evidence that the germ cells or gametes produced by cross-bred organisms may, in respect of given characters, be of the pure parental types, and consequently incapable of transmitting the opposite character; that when such pure similar gametes of opposite sexes are united in fertilization, the individuals so formed are free from all taint of the cross; that there may be, in short, perfect, or almost perfect, discontinuity between these germs in respect of one of each pair of opposite characters."

It must be remembered that heredity and environment cannot be studied apart in relation to the development of children, for, however good the heredity may be in the case of a child, it cannot accomplish much without the influence of wholesome environment, which can be of such service in altering or modifying certain tendencies which are inborn. What Sir Frederick Mott calls "the fundamentals of the mind" are begotten with the body, and predetermine character and conduct. This has been demonstrated by Francis Galton's inquiry into the history of similar and dissimilar twins, which proves that dissimilar twins remain dissimilar in mental and bodily characters when brought up in the same environment, whilst similar twins brought up in different environment remain similar in mental and bodily characters. Environment, however, cannot produce mental power.<sup>9</sup> The experience and studies of numerous other investigators have led them to agree with Dr. Goddard's conclusion that two-thirds of all feeble-mindedness is due to heredity.<sup>10</sup> Dr. Barr, chief physician, Pennsylvania Training School for Feeble-minded Children, Elwyn, states:

"The family histories collated in the institutions and hospitals of our land form in themselves a library of tragedies which would convince the most sceptical of the magnitude of race suicide, increasing with each generation. In my individual study of 4,050 cases of imbecility I find 2,651, or 65.45 per cent., caused by malignant heredities, and of these 1,030, or 25.43 per cent., are due to a direct inheritance of idiocy, and 280, or 6.91 per cent., to insanity."

Dr. Paul Bowers, who is superintendent of a hospital for the insane at Logansport, Indiana, has gathered data from a personal examination of more than 5,000 prisoners; he found that the antecedents of 44 per cent. of the examined convicts were psychopathic individuals, who were insane, feeble-minded, epileptic, criminal, or suffered from organic or functional disease of the nervous system.

On the other hand, careful inquiry into the family histories of the progenitors and the collateral members of ancestral stocks will generally show that a child born sound in mind and body is begotten by parents sound in mind and body themselves, whose stocks are free from any neuropathic or physical taint. Some consider that the heredity of mental deficiency is in accordance with the Mendelian laws if mental normality be regarded as the dominant and mental deficiency the recessive character. It has never been known for two mentally defective individuals to become the parents of a normal child.

#### *The Sterilization of Mental Defectives.*

The time has surely arrived when, instead of fostering the growth of the mentally defective, we should seriously consider the important problem of endeavouring to prevent their propagation. This can only be done by the sterilization of those who are definitely unfit to bring into the world healthy children. By the suggestion of sterilization, I do not mean asexualization, which has been practised in many countries for thousands of years. Experience has proved that the quieting of nerves and exaggerated emotional excitement is a primary and necessary factor in developing and training mental defectives, and as they suffer not only from mental and moral debility, but greatly exaggerated sexual impulses, asexualization is often of great service.<sup>11</sup> In ordinary sterilization there is nothing new, for it was known and practised by the Hebrews and Egyptians, in the South Sea Islands, among the American Indians, and in Scotland, on the insane, idiotic, epileptic, and on those suffering from transmissible disease. Plato suggested that the State should marry the best with the best, and the worst with the worst, and that the former should be encouraged to breed freely, while the offspring of the unfit should be destroyed. Aristotle was in favour of allowing children in excess of those required to die from exposure, all deformed children not being permitted to live.

The most frequent cause of congenital weak-mindedness is regarded by many to be neuropathic heredity. The subjects of mental deficiency are classified into idiots, semi-idiots, imbeciles or backward children, and moral imbeciles.<sup>12</sup> The incidence of idiocy among first-born is abnormally great, whilst the last child of a large family is liable to be weak-minded, apparently owing to the mother's nutrition being lowered by frequent pregnancies. Most children who acquire organic disease of the brain during infancy remain mentally defective, and epilepsy is responsible for about one-third of the cases.

Difficult labours are of considerable importance in the causation of mental deficiency, but in collective statistics in regard to these "difficult" labour is frequently accepted solely on the assertion of the mother. These statistics, however, seem to prove that a long labour is more prone to interfere with mental development late in life than forceps extraction.<sup>13</sup>

My own view, as that of others, is that when a child has been definitely pronounced by alienists to be of feeble mind, he or she ought to be prevented from ever having the chance of being a parent. Although this would be done for the advantage of the State, yet it is certainly for the benefit of the child, who, with no idea of responsibility, should be prevented in the future from bringing children into the world to be looked after by others. There is no interference with the sexual functions in the high-grade imbeciles, and moral imbeciles are especially apt to be troublesome.

In 1907 a law was enacted in the State of Indiana for the sterilization of confirmed criminals, idiots, imbeciles, and rapists. Since then other States have passed bills authorizing sterilization, and among them New York, Washington, New Jersey, California, Iowa, Connecticut, Utah, and Nebraska, as well as others. The terms of the Indiana law are:

"Whereas heredity plays an important part in the transmission of crime, idiocy, and imbecility, therefore be it enacted by the general assembly of the State of Indiana that on and after the passage of this Act it shall be compulsory for each and every institution in this State entrusted with the care of confirmed criminals, idiots, rapists and imbeciles, to appoint upon its staff, in addition to the regular institutional physician, two skilled surgeons of recognized ability, whose duty it shall be, in conjunction with the chief physician of such institution, to examine the mental and physical condition of such inmates as are recommended by the institutional physician and Board of Managers. If in the judgement of the Committee of Experts and the Board of Management procreation is inadvisable, and there is no probability of the improvement of the mental conditions of the inmate, it shall be lawful for the surgeon to perform such operation for the prevention of procreation as shall be decided upon as best and most effective. But this operation shall not be performed except in cases that have been pronounced unimprovable."

#### *Prevention of Marriage with the Certainty of Mentally Deficient Offspring.*

In a paper on "Sterility with reference to the State," which I read before the Section of Obstetrics and Gynaecology of the Royal Society of Medicine in March, 1922, I advocated, in order that mentally defective children should not be brought into the world, a State certificate of marriage. This would mean an Act of Parliament, and although one object

I have in view is legal sanction for sterilization of the unfit, yet such a certificate would obviate as far as possible the risk of marriage in persons affected mentally, or infected by the gonococcus, the *Spirochaeta pallida*, or tubercle bacillus. The ordinary family physician could give a certificate of health in the case of the female married for the first time; it would entail no more examination than is necessary for insuring life in any insurance office. The reasons which lead me to urge some such certificate are potent ones. The discovery of the presence of the infective organisms would enable the family attendant to advise the postponement of marriage until health was re-established. Gonorrhoea lessens the birth rate by preventing conception, and is the commonest cause of both absolute and relative sterility in women, the percentage being about 50 of all cases, and about 70 per cent. of the inflammatory infections in women are due to the gonococcus.<sup>14</sup>

It is estimated that syphilis causes about 25 per cent. of stillbirths and abortions, and at least 20 per cent. of the antenatal and neo-natal deaths.<sup>15</sup> This does not include those children with congenital syphilis surviving a month after birth, and who die later from debility, or who grow into delicate, puny children, always requiring extra care and attention. Of syphilitic women about 80 per cent. are married, and of the latter, according to Fournier, 75 per cent. have acquired it from the husband. Statistics regarding ten thousand consecutive labours in each of two American hospitals (the Johns Hopkins and Sloane) show that in the former the stillbirths due to syphilis were 32 per cent. of the total births up to fourteen days after birth, and that in the latter, 9 per cent. of the stillbirths were syphilitic, although all recognized cases of maternal syphilis were refused admission.<sup>16</sup> I do not suggest that men would willingly marry knowing themselves to be diseased, but examination would prove that they are or are not well enough for marriage, which could be postponed.

The strongest argument in favour of this certificate is that it would prevent the union of those with strong tendencies to insanity on either side, or those who showed signs of mental weakness, for they cannot be cured, and their offspring are defective. In the case of those with a strong history of insanity, or in presence of any mental deficiency, the certificate could be granted on the condition that one or both parties should be sterilized. This would prevent the unhappiness following the withholding of a certificate. The certificate would only be withheld in the case of the feeble-minded, or of a strong history of insanity on one or both sides, and in such cases the family physician would be bound to have the opinion of one—or if desired two—alienists. There is no suggestion that every possible care should not be taken with reference to withholding a certificate, for, as such a step necessarily entails an Act of Parliament, stringent regulations to safeguard the individual concerned, as well as the State, would be drawn up.

In some States of America, as already mentioned, sterilization of those mentally affected, as well as certain criminals, is already enforced. Although this is excellent as far as it goes, if sterilization were carried out earlier the vast majority of such persons would not be born. Although syphilis cannot be traced with certainty in Europe before the fifteenth century, it must, like gonorrhoea, have existed amongst the Egyptians from early times, and the reason more attention has not been paid to it until lately may be found in the fact that in former days its treatment was considered, especially by the Roman physicians, beneath their dignity. Although the effects of both the gonococcus and the *Spirochaeta pallida* are frequently terrible, yet, as there is now a possibility of complete cure, they cannot be compared with the appalling calamity of bringing into the world idiots and mentally affected children, whose condition cannot be cured, and who will, we know, if they survive and marry, certainly produce mentally defective offspring.

It is extraordinary how prolific these mental defectives are. Dr. Barr states that the sexual impulses are ever exaggerated, and they reproduce their kind from two to six times more rapidly than normal people. Dr. Bontor mentions a report of fifteen mentally deficient women who produced 116 children.<sup>17</sup>

Experience shows what such children will turn out to be in the future if they survive. They are feeble-minded, and more or less useless in the world, in spite of all the care bestowed on them in the training schools and other institutions in which they are well looked after. Although the cost to the State for the upbringing of these mental defectives is great it would not be complained of if permanent success

followed the treatment. But, as Dr. Stansfield truly says, "the trend of modern civilization, by its Poor Law system and its treatment of the unfit during childhood, tends to foster the growth of this class. The care given to physically and mentally unfit children may reduce the degree of unfitness, but if their improvement is such as to enable them to escape the Mental Deficiency Act they are turned out mental, moral, and physical weaklings, to return to the environment which was associated with the development of this unfitness. This supports . . . is also a strong argument in favour of . . . criminals."

In my opinion sterilization ought to be regarded as a social relief to prevent the advent of mentally defective children. State certificate of marriage will confer a blessing upon our country, for it will ensure the advent of healthy children only. If it became legal to sterilize mentally defective children their survival would be productive of no harm. But even though legislative power be never given in respect of the mentally defective I have said enough upon the *Spirochaeta pallida* and the gonococcus to support the argument in favour of a State certificate of marriage.

#### Method of Sterilization.

Sterilization may be done in the male by vasectomy, a small incision, after the application of cocaine, being made in the scrotum in the situation of the epididymis, the vas deferens isolated, a loop drawn out and divided, and about one quarter of an inch cut from it. The distal end is tied, and the end nearer the testicle left open, so that the secretion from it may be absorbed into the blood, preventing any disorder of metabolism; the contents of the scrotal sac are returned, and the small wound closed. In the female, the Fallopian tubes are divided, and the ends nearest to the uterus tied. The ovarian end of the tube is left open, thus permitting the absorption of the ovarian secretion. Dr. Van Meter makes a small slit through the peritoneal covering of the tube at its proximal end. The oviduct is hooked up and severed at its uterine junction, the severed end reflected on the distal side out through the incision in the peritoneal covering, and the small incision closed with continuous stitches of fine catgut. If there should be the least suspicion of the uterus being unhealthy, the oviduct should be ligatured.<sup>18</sup> Sterilization may also be brought about in both sexes by x rays, but it must be remembered that whereas vasectomy and salpingectomy do not in any way interfere with the functions of the interstitial cells, either in the testicle or ovary, yet the x rays may possibly do so.

I have pointed out the influence of the gonococcus in producing inflammatory affections in women, and the enormous number of infant deaths which are due to syphilis. These two conditions alone, quite apart from the mental and physical sufferings entailed on the parent, are, in my opinion, amply sufficient reasons why the antecedent and present condition of anyone about to be married should be inquired into before granting a certificate of marriage. Sir Frederick Mott says:

"For twenty years I was endeavouring to awaken the authorities to the necessity of combating venereal disease, for it was overwhelmingly proved that syphilis, besides being the sole cause of general paralysis of the insane, which accounts for 15 per cent. of admissions, is also a very frequent and sole cause of mental deficiency and organic dementia. Yet nothing was done until the Royal Commission on Venereal Diseases in 1914."

I have been particular to emphasize syphilis in my appeal for a State certificate, for it is a preventable disease. Everything which can be done to prevent the spread of syphilis will diminish enormously the proportion of cases admitted to hospitals, asylums, institutions for the blind, the deaf, and the dumb, and for mental deficiency due to congenital syphilis.

The authorities who can best give an opinion of real value are those who are superintendents of institutions for the feeble-minded. They assure us that, in spite of all we can do for these mentally defective children, they can never be really cured. As examples of what a man of defective mental type can do, I may quote family histories:

The first was carefully investigated by A. H. Estabrook. The two sons of a mentally defective man married degenerate women, from whom six generations, numbering 1,200 persons, were born, every grade of idleness, viciousness, pauperism, disease, insanity, and criminality, and of the total more than half the women fell into prostitution. By the year 1915 the clan had reached the ninth generation, and increased its evil record. It had numbered 2,820 individuals, half of whom were alive. Although the family was scattered widely over the country and the environment produced no benefit. They still showed the same

feeble-mindedness, indolence, licentiousness, and dishonesty." The cost to the State had risen to 2,500,000 dollars. The one who investigated this family history most justly remarked that this evil might have been averted by preventing the reproduction of the first degenerate.

The second was the striking example of superiority and degeneracy in the well known case of the Kallikak family, published by H. H. Goddard.<sup>21</sup> A young soldier of good stock had a son by a feeble-minded girl, from whom there have descended in a direct line 480 individuals, of whom only 46 are known to have been normal. Of the rest, some are unknown or doubtful, and the others turned out to be feeble-minded, alcoholic, some of the women grossly immoral (mostly prostitutes), epileptics, and criminals. Years later he married a woman of good family, who bore several children, and the descendants turned out well, many of them being distinguished. The two families lived in the same environment.

These two families show what evil can be done from the feeble-minded scattered all over the empire.

In conclusion, I need hardly say that I am fully aware of the opposition my suggestion will meet with in this country, not only on sentimental grounds but on those of State interference with the liberty of the subject, and the possibility of evasions, which would certainly be attempted. Nevertheless, those who seriously consider what is best for the future of our race, in view of the facts I have mentioned, cannot but agree that it ought to be of the highest importance; we should at least endeavour to secure the advent of only healthy children, and as we have the means at our hand we ought to avail ourselves of them and prevent the propagation of the mentally defective.

## MINERS' NYSTAGMUS.

BY

A. S. PERCIVAL, M.A., M.B., B.Ch.CAMB.,  
OPHTHALMIC REFEREE, COUNTY COURTS 1 AND 2.

In the first report of the Miners' Nystagmus Committee, published last year, we read:

"The Committee have unanimously reached the following conclusions:

- "1. The essential factor in the production of miners' nystagmus is deficient illumination. . . .
- "2. The deficient illumination is due to the low illuminating power of the safety lamps generally used by miners. . . .
- "3. Workers at the coal-face are more affected than other underground workers, and this appears to be due to the unrelieved blackness of the coal and the greater need for accurate vision.
- "4. Distinct signs of nystagmus are present in a large proportion of coal miners, though only in a small proportion do the symptoms ever become so severe as to cause even temporary incapacity for work underground."

With these conclusions I think no one who has practical experience of the disease in the counties of Northumberland and Durham will agree, but of course unsupported assertions are absolutely useless in contesting the point. I have therefore, owing to the courtesy of the Coal Trade Office and of the officials at thirty-two pits in these two counties, obtained some details of 36,232 underground workers during the year 1922, with notes of the character of the illumination and of the average thickness of seams worked at each pit during that year. The numbers are sufficiently large for reliable statistical conclusions to be drawn from them.

The first point we wish to determine from the facts presented is whether in these pits deficiency of light or something connected with coal hewing is the more important cause.

Here what are technically called two attributes are to be investigated, and therefore four independent class frequencies

must be given in order that a valid conclusion may be drawn. (If  $n$  attributes are under consideration, no conclusion can be drawn unless  $2^n$  class frequencies are given, which must be independent of each other.) Of these 36,232 underground workers, 11,383 were hewers and 24,849 were non-hewers; 103 of the hewers and 59 of the non-hewers acquired nystagmus. It is only necessary to compare the proportion or the percentage of the nystagmus cases among the hewers with that of the nystagmus cases among the non-hewers—that is:

$$\frac{103}{11,383} : \frac{59}{24,849} \text{ or } 0.904853\% : 0.237434\%$$

Clearly, if the percentages were equal, nystagmus would be quite independent of hewing; if they were even nearly equal, deficiency of light might be the essential cause of the disease, but we see that the percentage amongst hewers is nearly four times greater than that amongst non-hewers, so we are driven to the conclusion that hewing, or something connected with hewing, is of far greater importance than mere deficiency of light. I have given the percentages to six decimal places when three figures would be quite enough, but I wished to guard against any ambiguity in using less exact figures. If hewing were the only cause of the disease, of course there would be no cases of nystagmus amongst the non-hewers. If both percentages be multiplied by the reciprocal of the greater ( $\frac{1}{0.904853}$ ) we get the ratio 1 : 0.2624.

The difference ( $1 - 0.2624 = 0.7376$ ) gives a sort of measure of the degree of association, where 1 indicates complete association, and 0 indicates that the percentages are equal or that there is complete independence.

There are four other pits, employing altogether 7,452 underground workers; as the details about these are not so complete, for the period is not limited to the year 1922, they are here considered separately. On comparing the proportion of the nystagmus cases amongst the hewers with that amongst the non-hewers we have:

$$\frac{34}{2324} : \frac{20}{5128} = 1.463\% : 0.4179\% = 1 : 0.2856,$$

which gives the degree of association of hewing with nystagmus as 0.7144. When all the cases are added together, making a total of 43,684 underground workers, the degree of association becomes 0.7363.

It is true that the prevalence of nystagmus amongst hewers is noticed in the conclusion (3) of the report, but the explanation given is more than doubtful.

All underground workers are exposed to "the unrelieved blackness of the coal," and "the accurate vision" required by a hewer with a pick does not involve macular vision, but a keen sense of projection from extramacular parts of the retina, as has been so well insisted upon by Dr. Freeland Fergus under the name of alignment. I have examined several miners with macular vision less than 6/24 who have been admitted by their comrades as more efficient coal getters than themselves. In a very dim light macular vision is almost useless, for the fovea is a blind spot, as anyone can prove for himself.

I hold that nystagmus is excited by the long-continued strained position of the eyes in an unusual position. This view is no longer fashionable—chiefly, I believe, because it was found that the incidence of nystagmus was rather less in thin than in thick seams. But in undercutting a thin seam the miner lies on his side while the position of his eyes is rather downwards; whereas in top-holing a thick seam the gaze is directed obliquely upwards, a far more uncomfortable position for the eyes to maintain. Consequently, the greater frequency of nystagmus in thick seams supports the view that the constrained position of the eyes is the important factor in exciting the disease.

Unfortunately, in most cases only the average thickness of the seams worked at each pit has been given me—for example, St. Hilda, 3 ft. to 5 ft. 6 in.—so that it is impossible to draw any conclusions as to the incidence of the disease at 2 ft. and under, at 3 ft., 4 ft., 5 ft., as would have been desirable. In the few cases in which more precise data have been given the numbers are too small for any reliable conclusion to be drawn.

The same difficulty of insufficient data occurs with regard to the character of the illumination. Most of the pits use both oil lamps and electric lamps; in no pit are electric lamps used solely. I have been told that in the Dean and Chapter pit, where Messrs. Bolckow, Vaughan, and Co. had gone to the expense of providing excellent electric lamps to

the miners, the result only was to increase the cases of nystagmus notified. I have no wish to overstress this point, but I think that I have said enough to show that in this neighbourhood all the evidence is against deficiency of light being the principal cause of exciting the disease.

My own view is that there is a predisposition to the disease, that perhaps 5 per cent. of all children born have this idiosyncrasy, and that coal hewing is a very important factor in exciting an active nystagmus. Anyone who has once acquired miners' nystagmus will, after loss of all the symptoms, assuredly acquire it again if he returns to his old employment underground; at least, that is what my experience has taught me. I have seen two cases in accountants who said they always worked in a good light; these are analogous to Snell's ceiling paperer. If this contention be confirmed by others, the patient should never be allowed to go down a pit again, but must be given compensation for a limited period—say twelve months or so—while recovering from his symptoms, to give him time to obtain other employment.

## POSTERIOR GRAVITY DRAINAGE IN EMPYEMA:

### THE STRATEGIC SEAT OF ELECTION.

BY

SIR JOHN O'CONOR, K.B.E., M.A., M.D.,  
SENIOR SURGEON, BRITISH HOSPITAL, BUENOS AIRES.

THE plan herein described has been employed, during the past two years, in a series of cases in the British Hospital, Buenos Aires, by my colleague Dr. Fehilly and by myself, with such uniformly satisfactory results that I think it merits the attention of those who have to intervene in this condition. The reason for its adoption was prolonged failure with other methods to prevent post-operative stagnation of pus within the pleural cavity, as evinced by general symptoms and by the quantity of discharge that always followed changing of tube, which only required a cough or alteration in the position of the patient to prove that the operation had failed to establish immediate automatic evacuation of purulent secretion.

Without wishing to detract from the general value of conclusions formulated on clinical deductions I am satisfied that in this instance surgical reasoning has, for generations, been unwittingly deflected by academic illusions. In the recent edition of Da Costa's *Surgery*, for instance, we find:

"I agree with Hutton that a portion of the sixth rib in the mid-axillary line should be removed. . . . The reasons given by Hutton for the selection of this rib are . . . it is over the portion of lung which expands last. . . . An empyema is drained only partly by gravity, and most of the fluid is really forced out and the cavity is obliterated by lung expansion. . . . If an incision is made anterior or posterior to this point the expanding lung will block the drainage opening, and a pus cavity without drainage will remain in the mid-axillary line. . . . Such an incision permits a patient to lie on his back without making any pressure on the drainage tube."

A few days after the receipt of this new edition, Dr. Fehilly called my attention to the above statements, and after studying them, we went purposely to the wards and examined, in detail, the wounds of five post-operative cases that happened to be under treatment. The result was that, so far as our method was concerned, every line of Da Costa's quotations of Hutton's theories contained a travesty of fact. In four of the cases there was free dependent drainage of a sinus tracking upwards and inwards towards the spine, and in each of these the lung had expanded and air was freely entering the base in the axillary line. In the fifth, the most recently operated on, there was a well defined cavity directly in front of the opening completely shut off from the axillary border of the chest by adherent lung tissue. In each instance there had been prompt defervescence and marked daily decrease in the general symptoms. There was not the slightest reason for suspicion of any secondary pus cavity. The expanding lung did not cause an hour-glass contraction of the sinus, nor had it interfered with drainage in a single instance, and gravity drainage was perfect and in no way affected by dorsal decubitus, which position, by the way, the patients had voluntarily adopted during the first week after operation.

The result of these examinations confirmed previous experience of a method founded on anatomical facts—for example, Cunningham's *Anatomy*, p. 930, Fig. 630—and on x-ray study of the normal living thorax which demonstrated the existence of a distinct potential sinus in the pleural cavity, between the scapular line and vertebra, beneath the

ninth and tenth ribs, formed at the junction of the parietal and diaphragmatic pleura. This, combined with the fact that these patients do not pose in bed in the prone position but invariably assume a supine slope, and that those who have a resection of rib performed for empyema on textbook lines have a tendency to tilt the affected side upwards in order to avoid pressure pain, rendered it obvious that this posterior angle was the strategic site for gravity drainage in general suppurative pleuritis. And personal experience convinces me that the lung expands more rapidly if unhampered by having to force liquid uphill.

It is hardly necessary to add that this seat of election is the ideal one for an encysted empyema between lung and diaphragm, not to mention the ready ingress it affords in cases of suppurating hydatid cysts, abscess of the liver, or subdiaphragmatic abscess, which have perforated the diaphragm on their tracking to a bronchus.

In parenthesis I wish to remark that whenever an abscess or cyst is situated near the posterior surface of the liver posterior drainage should always be adopted; otherwise, as in ill placed thoracotomy for empyema, the "external" sinus or internal flask pocket is certain to remain. When practicable other subdiaphragmatic "collections" should be similarly dealt with. Whenever an exploring needle proves the existence of pus in the chest word is sent to the theatre to prepare at once for operation.

Before commencing local disinfection with the patient's elbow hanging at the side the inferior angle of the scapula is determined by the index finger, and from its tip a line two and a half inches long is traced vertically downwards with a stick of silver nitrate. The lower point of this line indicates the topographical position of the inferior border of the ninth rib, and affords a fixed central point for any form of subsequent incision for the evacuation of "free pus" from the pleural cavity.

Either by the open method is administered, and the patient, with the elbow maintained at the side by an assistant, is carefully rolled over on the table sufficiently to facilitate the insertion of an exploring needle, and (if the result is positive) a four-inch curved incision is made, with its centre at the point above noted. With a few strokes of the knife the skin and subcutaneous tissue are divided, the fibres of the latissimus dorsi (which run upwards and outwards) are separated by a blunt dissector, strong retractors then make a free space for denuding and resecting two inches of the ninth rib, and a touch of a scalpel to the pleura completes an operation which depends on the behaviour of the divided intercostal artery as to whether it will be a one or three minutes' procedure. (N.B.—There must be no hesitation in removing two inches of the tenth rib in the same line if there should be any suspicion of defective dependent drainage.) Two short "gas-pipe" drainage tubes are then inserted into the cavity; these are transfixed with safety pins, under which a thin piece of gauze is packed lightly into the parietal wound, and dry gauze, wool, and a bandage applied. The outside dressing is changed as often as it becomes saturated until the second day, when it is superseded by a four-hourly warm mercury perchloride (1 in 3,000) fomentation, wrung dry. I never apply any form of impermeable tissue with a "perchloride" fomentation, which, by the way, I consider excellent in septic surgical cases. The drainage tubes are also removed on the second day, and two large wisps of silk-worm gut substituted. These wisps are made by doubling twenty strands of silkworm gut and ligating them with a piece of fine silk about half an inch from each end. They afford excellent drainage, do not become foul, and never produce the pyogenic track which invariably accompanies the prolonged use of rubber tubes in wounds.

As soon as the patient can be safely raised into the sitting posture, and subject to no cough supervening, low level trickling irrigation with warm hydrogen peroxide solution (4 tablespoonfuls to a litre of water), followed instantly with warm carbolic lotion (1 tablespoonful to a litre) is carried out three times daily. The "peroxide carbolic" lotion rapidly diminishes smell and, in its own incomparable way, promptly induces vigorous and healthy pale vermilion granulations. The wisps are removed prior to each irrigation, and afterwards reinserted. (It may be well to mention that, to obviate the possibility of these wisps appearing, the sister in charge ties each one, about the centre, with a piece of silk, and passes a safety pin internal to the chest, such cases are treated in the "continuous catheter" method, and are given generous diet with wine, beer, or stout, and meals, with an occasional port wine and egg custard.)

temperature rose suddenly. His bed was tilted, and soon after the temperature fell. The tilting was carried out in three-hour stages for a week, and a week later as he felt well he left the hospital and I lost trace of him.

The patients liked the treatment and would ask to have their beds tilted. I have suggested this treatment in private practice, but an objection raised is that the bed may break.

CHARLES J. HILL AITKEN, M.D.

Kilnhurst, near Rotherham.

## British Medical Association.

### CLINICAL AND SCIENTIFIC PROCEEDINGS.

#### WESTMINSTER AND HOLBORN DIVISION.

##### *Sterilization of the Unfit.*

At the annual meeting of the Westminster and Holborn Division of the Association, which took place, preceded by a dinner, at the Criterion Restaurant on April 12th, Dr. KENNETH HAY presiding, a paper was read by Dr. R. A. GIBBONS on the subject of a State certificate of marriage and the sterilization of the unfit. The paper is printed at page 754 this week.

In the discussion that followed Dr. B. DUNLOP declared himself entirely in agreement with Dr. Gibbons, although he approached the end which Dr. Gibbons had in view by a different route—namely, that of birth control propaganda. Syphilis was, perhaps, the chief factor in causing mental deficiency, and birth control advocates held strongly that the incidence of venereal infection would be largely diminished if celibacy or postponement of marriage no longer widely prevailed. A large proportion of people, especially amongst the better educated classes, were deterred from marriage by the fear of subsequent economic struggle. A rise in the marriage rate would be a very important factor in arresting syphilis. He had been interested in Dr. Gibbons's reference to the relative frequency of deficiency in the case of the first-born; he had discussed this subject with Major Leonard Darwin, who as a eugenicist attributed the higher proportion of defectives—not necessarily mental defectives—among first-born to the risks to which they had been exposed at parturition. With regard to the operations described by Dr. Gibbons, it had been shown by recent investigations that such operations actually resulted in an improvement of the health of the individual, so that the objection on the ground of hardship was thereby met.

Dr. F. HOWARD HUMPHRIS noted that Dr. Gibbons had said that the operations he described did not interfere with the functions of the interstitial cells, either in the testicle or the ovary, whereas  $\alpha$  rays did so interfere. The fact seemed to be, however, that  $\alpha$  rays could bring about sterility while at the same time increasing potency. He quoted a foreign  $\alpha$ -ray worker who had declared that while other tissues were affected by  $\alpha$  rays to the point of actual degeneration, interstitial tissue more or less escaped. This same worker had practised temporary sterilization of husband and wife in alternate months by means of  $\alpha$  rays, and according to the report this appeared to be as practicable a method of sterilization as surgical operation, while it had the advantage that afterwards it could be abandoned if it was thought that, after all, there was no harm in conception being allowed to take place.

Mr. C. E. WALLIS, as one who had been associated for twelve years with one of the largest industrial clinics for the treatment of imbeciles of both sexes, said that it was necessary to distinguish between the confirmed and hopeless imbecile and the improvable imbeciles. He could not imagine anything in the nature of operation upon these latter being tolerated in this country. Even such a trifling operation as vaccination aroused intense opposition in some quarters. But while operation would not be tolerated, it was possible that  $\alpha$ -ray applications, especially if they caused only a temporary sterilization, might be regarded with more tolerance.

Dr. KENNETH DICKSON said that it was very important for medical men to take an interest in these sociological subjects. The bulk of the profession needed converting to the duty of having and expressing an opinion on these matters. An ex-superintendent of the Indian police had told him that on such a subject as the reform of the criminal classes in India the medical men out there had nothing to say, regarding it as a question beyond their concern. But the medical profession was the only united body of men whose opinions on such subjects

were likely to be adopted by the community if they were supported by reasonable arguments. It seemed strange that the greatest propagandist in these sociological fields should be a highly distinguished churchman. Dean Inge would go down into history as one of the philosophers of the present day—one who was judged to be a pessimist only because he refused to prophesy smooth things—and the medical profession would do well to follow such a man in his efforts to educate public opinion.

Mr. A. L. W. WHITEHOUSE reminded the meeting of the various instances of genius allied to insanity or mental instability, and urged that the point of view of the ordinary citizen might be that sterilization would have a regrettable consequence in stopping the supply of Byrons and Samuels Johnsons.

Dr. GIBBONS, in reply, made it clear that his paper had nothing to do with birth control. The object he had in view was to secure the bringing into the world of healthy children, that all about to be married should have a State certificate of health, and if such could not be given marriage should be postponed for the time being. The raising of the age of marriage, of course, lessened fertility. The average number of children to a marriage, supposing the marriage to be fertile for the full child-bearing period, should be ten. Four children to a marriage were necessary to continue the State in view of the fact that some would die before maturity and some would not marry. But the results of the voluntary confidential census among intellectuals showed that the average number of children to a marriage was less than two. This would do away in time with the need for birth control propaganda. Already in France the seriousness of the position was realized and strong action was taken with regard to contraceptives. With regard to the first-born the frequency of defect might be due to difficult labour. He had often found also that the last child of five or six was deficient, apparently because the nutrition of the mother had run down. With regard to  $\alpha$  rays he had been of opinion that powerful  $\alpha$  rays must certainly affect the interstitial cells, though about that, of course, only an  $\alpha$ -ray expert could speak.

## Reports of Societies.

### OSTEO-ARTHRITIS AND RHEUMATOID ARTHRITIS.

A GENERAL meeting of Fellows of the Royal Society of Medicine was held on April 23rd, with the President, Sir WILLIAM HALL WHITE, in the chair. The meeting discussed the question of osteo-arthritis and rheumatoid arthritis.

Sir ARCHIBALD E. GARROD opened the discussion. After a gracious and graceful allusion to the pioneers of the past, he said that these chronic articular diseases formed a very obscure part of medicine. We had lost our way in a labyrinth of cross-classifications and multiple nomenclatures were sure signs of ignorance. The osteoarthritic lesions developed insidiously in old people. Often there was no antecedent acute or subacute arthritis; but osteoarthritic changes might develop from any prolonged or recurrent inflammatory lesion—witness the arthritis of haemophilia. All were familiar with the knee joint trouble of middle aged women. These lesions were quite distinct from infective troubles—these he preferred to class under the heading of rheumatoid arthritis. Immense changes had taken place during the last thirty-five years in their conception both of rheumatoid and osteoarthritic. They were, however, not much advanced in relieving the conditions; indeed, there were still some who did not believe in the difference between the two conditions. There was a decided difference in distribution. Osteoarthritic attacked frequently the end-joints of the hands—joints little affected by the more acute disease. The carpo-metacarpal joint of the thumb was frequently the site of osteoarthritic changes, but was little liable to damage by infective rheumatoid troubles. Sir Arbuthnot Lane had many years ago insisted on wear and tear as an important factor in the cause of osteoarthritic. The speaker believed that it was an important contributory factor, but there must be a predisposing cause. He would call attention to the rare condition of alkaptonuria. In those cases the cartilages of the ear became black with ochronosis the cartilages of the ear became black. These patients showed a very special liability to develop osteoarthritic. Two German observers had reported a family with an alkaptonuric father. Four of the children

suffered from ochronosis and osteo-arthritis; the other four escaped both troubles. There was therefore strong evidence of a special predisposition to the disease. He was tempted to ask, What was rheumatoid arthritis? It was apparently an infective malady; but was it due to one specific infective agent, or was it a disease, like malignant endocarditis, which might be due to a variety of organisms? Sometimes one could find an infective focus, often suppuration around teeth, and removing the focus might lead to the recovery of the patient. But in the majority of cases, search how one would, no definite infective focus could be found. The cases of this type were very many.

Experience had led Sir Archibald Garrod to think that there was a specific disease closely simulated by diseases due to other causes. Such were the arthritis of bacillary dysentery, gonorrhoeal arthritis, and the arthropathy of psoriasis. He well remembered a girl under his care years ago at St. Bartholomew's Hospital. She was a public singer and dancer and suffered severely from psoriasis, with arthritis of many joints. She was apparently completely crippled with rheumatoid arthritis. Under arsenic (also convenient because she suffered also from that curious condition, intermittent hydrarthrosis) she showed great improvement. The psoriasis went away and with it the joints improved. She was able to sing and dance again. Unfortunately the condition recurred. He thought that in this condition there was a perfectly distinct lesion waiting to be investigated. Drugs he did not consider of much value in rheumatoid arthritis. Vaccines were of prophylactic value, but he had never seen recovery follow vaccine treatment alone.

Protein shock gave great relief to patients at the time, but he doubted if the effect was lasting. Treatment at watering-places was valuable later when the subacute stages had subsided and before deformities were established. The same applied to massage of the muscles. Their aim should be to kill off the infection before it did its irrevocable damage to the joints. In osteo-arthritis also drugs were not of much value. He thought that iodides with arsenic sometimes did good to patients just beginning with Heberden's nodes. In hip cases drugs were no good at all. Watering-places with massage and electrical treatment sometimes helped. If he could direct the discussion at all, he would like to ask—

1. What is the difference between osteo-arthritis and rheumatoid arthritis?
2. Is rheumatoid arthritis due to a specific infection or not?
3. What is the real value of modern bacterial knowledge applied to these conditions?
4. What can be done for the patient?

Dr. M. Cassidy feared that the few remarks he would have to make might be regarded as being agnostic or even reactionary. He would begin by expressing his profound conviction that the importance of infective conditions in the etiology of these diseases was at the present time grossly overrated. Particularly was this the case with rheumatoid arthritis. He regarded rheumatoid arthritis as a clinical entity—a somewhat uncommon disease, and one almost entirely confined to women, whom it attacked in early life. In his opinion it was uncommon to find any septic focus, however carefully it was looked for, in a genuine case of rheumatoid arthritis. As a rule these patients had perfect teeth, there was no evidence of intestinal toxæmia, the urine was sterile, and the respiratory tract, tonsils, ears, and genitalia appeared healthy. The fluid aspirated from the joints was invariably sterile; sterile also, he believed, was the synovial membrane itself. Nine years ago Mr. Percy Sargent and he scanned microscopically and bacteriologically small fragments of synovial membrane removed during life from rheumatoid joints. In only one out of fifteen cases was an organism (a streptococcus) recovered, though cultures were made from the excised synovial membrane aerobically and anaerobically in all the usual media. He suspected that their one positive result was a skin contamination. He confessed to being a little sceptical as to whether rheumatoid arthritis was infective at all. There was little in its clinical aspect, apart from the occasional pyrexia, to suggest an infective process. It might run a steady progressive course, with remissions and exacerbations, of thirty or fifty years, with never a visceral complication. Pleurisy, pericarditis, and endocarditis occurred very seldom, and then probably accidentally. The only really common complication was fibrositis, and he was satisfied that not only was there a definite tendency to heredity in rheumatoid arthritis but also that relatives of those patients were

specially liable to fibrositis. He often wondered if both conditions were not metabolic rather than infective, and wished that the biochemists might tear themselves away, if only for a few months, from tests of renal function and blood sugar curves and devote themselves to reinvestigating the metabolism of gout, rheumatoid arthritis, and fibrositis. All that he had said referred to genuine rheumatoid arthritis, the disease as described, for instance, in Allbutt's *System* sixteen years ago by the distinguished opener of the debate. He freely admitted that there was a large group of cases of chronic infective arthritis which might resemble sometimes very closely rheumatoid arthritis at some particular stage in the disease, but rarely throughout its course. In this group an infective focus was often readily demonstrable and its removal often led to cure. But it had been his misfortune to see many cases of rheumatoid arthritis lose all their teeth, submit to a long course of inoculations, and never in his experience was the course of the disease arrested by these measures. What he had said of rheumatoid arthritis held good for many cases of osteo-arthritis. Some cases of this condition were infective, but there were other causes besides infection. Personally he believed that some osteo-arthritic joints were primarily gouty although they had never been attacked by typical acute gout. He remembered two sisters with subcutaneous nodules along the exterior tendons of the hands and feet. Mr. Max Page excised some of these nodules; they contained much uric acid. At the present time both of these sisters were developing osteo-arthritic changes in the knees and other joints. He found it difficult to believe that these conditions were not of gouty origin, though there had never been anything readily resembling acute gout. They were all familiar with the acute onset of osteo-arthritis of the knees, with or without the simultaneous appearance of Heberden's nodes in the fingers, in many women at the time of the climacteric. Surely that must be metabolic rather than infective. Yet these patients, like so many arthritics at the present time, were doomed to become edentulous, and probably also to suffer inoculations.

Dr. F. J. Poynton said that just over twenty years had elapsed since, with Dr. Paine, he had demonstrated the experimental production of osteo-arthritis with a streptococcus obtained from a knee-joint, damaged by osteo-arthritis, of a patient who died by misadventure from carbolic acid poisoning. He thought that since then the importance of infection in these diseases had been more and more recognized. They had shown later two other experimental results: (1) that the same infection in varying virulence might produce various types of arthritis; (2) that a monarticular arthritis might arise from a blood infection. There still remained the difficulty of deciding whether there was a particular disease rheumatoid arthritis or whether it might arise from various infections. It was tempting to believe that just as a particular streptococcus might produce acute rheumatism so a particular staphylococcus might produce rheumatoid arthritis; but whether in human disease any line could be drawn between streptococci and staphylococci was to him doubtful. The various changes in the joints he looked upon as of great practical importance, but as secondary incidents connected as to the prime cause and not in themselves specific. His experience inclined him to believe that the disease was more under control than formerly, and this he attributed in part to the recognition of infection and local foci. The term "local focus," now so often heard, was a fundamental conception, but was dangerous in its simplicity. Very attractive, because sometimes true, was the picture of such a focus discharging infective agents into the system and another showing a cure after removal. The problem in rheumatoid arthritis was unfortunately much more complex and involved one in the great and difficult questions of the behaviour of infections within the body, of the methods of resistance of the body to infection, and the influence of outside factors on the resistance. Could, for example, an apical abscess at the fang of a tooth produce rheumatoid arthritis when it was an almost solitary lesion? How were they to explain the fact that after a septic month had been thoroughly cleansed a rheumatoid arthritis might continue uninfluenced for years? Either the septic month was only an incident, or, if the cause, secondary foci within the body had taken on an active phase. Lack of knowledge of the life history of infection in the body was the obstacle now in the treatment of the disease. It was quite possible to keep removing local foci in a patient who could not bear the strain of active measures and later to discover that the activity of the process was dependent upon factors within the body itself. Unhealthy foci should certainly be

treated, but if we held to the crude idea of a local focus as the explanation of rheumatoid arthritis he thought that cases, of which there were many, in which no foci were apparent might suffer from spasmodic efforts for the removal of suspected foci. Dr. Poynton thought that vaccine treatment was indicated when a micrococcus was isolated in pure or almost pure culture from an obvious local focus, but he thought it would be helpful if a new aphorism could be added to medical literature. It was this: Many cases of rheumatoid arthritis show no definite local focus, but there is no case of rheumatoid arthritis from which a micrococcus cannot be isolated. Did a vaccine isolated from the tonsil, the faeces, the urine, or the nose do service when there were no local signs of disease in these situations? He believed that auto-intoxication from the bowel was the most popular theory of the causation of rheumatoid arthritis. He would treat with care all bowel complaints as they arose, but not from the conviction that they were the cause, but rather the result of the infection. He laid much stress on the treatment of the nervous system. Organotherapy was indicated in cases at the menopause and in cases with severe vasomotor symptoms, but its value difficult to appraise. He had always leaned to curtailing carbohydrates, but Pemberton and his school had carried this line of treatment to considerable lengths, and it was possible we should learn more of the influence of control feeding upon resistance to infection. Local measures were legion. He did not advise radiant heat in cases which were worse in the summer time. He had often noticed relief in hypertrophic arthritis from ionization. His experience of osteo-arthritis of the hip accorded with that of others in the frequency of injury as a factor. In the earlier stages treatment on the lines of tuberculous hip disease seemed to him the most promising. Often these patients, athletic and intolerant, would not wear a splint. Treatment at a spa might do good in these cases provided that the joint could be rested.

Dr. A. F. Hurst called attention to two very constant symptoms of rheumatoid arthritis. There was, during the acuter phases, sweating from the palms of the hands and from the feet; there was an increased pulse rate. He thought that the prognosis was better than some would have them believe. In every case there were infective foci, although often they were difficult to find. He thoroughly believed in the value of x rays in the diagnosis of foci connected with teeth. He cited a case in which a medical student suffered very severely from rheumatoid arthritis. It was thought that he would be crippled for life. At first no lesion of the teeth was discovered. He was sent back to the dentist, and finally a very slight change was detected in one tooth. This was removed. There was a violent reaction. Vaccines were made from the tooth and given to the patient. Again there was a violent reaction. More teeth were removed. The patient was now quite well, and was present that evening. After teeth, tonsils. Many normal-looking tonsils were the seat of infection, but intestine must not be forgotten. Often these cases suffered from achlorhydria, and in these cases large doses of dilute hydrochloric acid did good. Several times Einhorn's tubes had given him organisms from the duodenum, from which it had been worth while to prepare vaccines. While the arthritis was acute, and the joint tender and painful, the affected parts ought to be fixed. Deformity could be prevented by keeping the joints in good position. His treatment was a combination of rest and removal of foci. After the active disease had died out complete ankylosis was rare. Yet often patients remained bedridden. For these, treatment by orthopaedics and psychotherapy was often the best thing. Persuasion, explanation, re-education—all three were necessary. A large proportion of these helpless cripples could, if they would, take up their bed and walk.

Dr. T. S. P. STRANGEWAYS demonstrated pathological specimens to show that there were at least six types of arthritis at present included under the name "rheumatoid arthritis." In order to avoid new names he had provisionally classified these types as follows: (1) capsular, (2) dry, (3) adhesive, (4) rarefying, (5) villous, (6) infective.

In the *Capsular type* the joint changes were practically confined to the capsule of the affected joint. The synovial membrane was not much altered. The capsule itself showed some degree of thickening and fibrosis. The articular cartilage, as a rule, appeared normal, but in the later stages of

the disease it might show atrophy over areas of pressure. The bones of the articulation were normal. This type could be found in both sexes, but was more common in the female sex. The patient complained of loss of strength and feeling of slackness. The joints were swollen, and sometimes were stiff and painful, and often there was a leather-like creaking. Apparent recovery, or great improvement in the symptoms, might take place within a few months of the onset, but a relapse nearly always followed within a longer or shorter period. Although complete recovery might occur, the patient, as a rule, gradually became more and more helpless and crippled.

In the joints of the *Dry type* the characteristic change was the absorption of the synovial fluid which in the later stages of the disease was completely absent. The capsule became atrophied, fibrous, and tightly contracted, gripping the bones of the articulation firmly, and thus causing the articular surfaces to lie in close contact with each other. The synovial membrane was dry and had the appearance of parchment. The cartilage was atrophied from pressure. The bones of the articulation were not altered. This type was seen more commonly in the female sex, and in its early stages it was sometimes diagnosed as chronic rheumatism or fibrositis. There was no swelling of the joints, but as the disease progressed movement became more and more difficult and eventually impossible, and this often led to a mistaken diagnosis of "bony ankylosis." In spite of the close contact, true adhesions between the joint surfaces did not take place, but if the joint was opened the articular surfaces would be found stuck together so that some force was required to separate them.

The *Adhesive type* began with inflammatory changes in the synovial membrane and capsule. These changes were associated with the formation of a vascular granulation tissue which spread over the cartilage and became adherent to it, thus causing vascularization of the perichondrium and of the deeper layers of the cartilage. This was followed by the erosion and replacement of the cartilage by a vascular inflammatory connective tissue which later invaded parts of the calcified cartilage and the bone underlying it. As this inflammatory process spread, vascular adhesions were formed in the joints between adjacent articular surfaces. This acute condition of the joint might persist for months or years, but eventually tended to subside. The inflamed capsule and synovial membrane, together with the newly formed connective tissue and adhesions, gradually became less vascular and eventually were replaced by firm fibrous scar tissue in which development of new bone might occur, leading to bony ankylosis. This type appeared to be confined to the female sex. The patients were thin and wasted, and several joints were usually attacked. They complained of intense pain on movement, but apart from the joint conditions were not in bad health. After several years the disease usually became quiescent, but the patient remained permanently crippled owing to the joint changes.

In the *Atrophic type* the bones in the affected joint were greatly rarefied, and eventually the cancellous tissue was practically replaced by pure fat, so that the bone cut readily with a knife. Accumulation of fat was also present in the muscles and other tissues of the limb, which in extreme cases became so friable and fatty that on forcible extension they broke like a carrot. The capsule, synovial membrane, and articular cartilage were atrophied. In the smaller joints atrophy of the bones might be extreme, especially in the joints of the hands when they had been used, in spite of the joint changes. The carpi were fused together, and after maceration had a lace-work appearance resembling that of white coral. In the early stages inflammatory changes took place in the capsule, and as these subsided bony ankylosis of the larger joints often occurred. In the late stages of the disease the atrophy of the limbs, especially of the hands, was a marked feature. This type appeared to be confined to the female sex, and the patients were usually well nourished and cheerful. There might be a history of exposure, such as sleeping in a damp bed or sitting in a cold train when wet through.

The *Villous type* was seen in both male and female patients who complained of the joints feeling weak and somewhat painful on movement. There was considerable swelling of the affected joints, which felt soft and full of fluid. Although some increase of synovial fluid might be present the swelling was chiefly due to the presence of a number of large villi, some smaller pedunculated villi, which might be seen on the whole of the synovial membrane was covered with them. On opening the joint these villi appeared as soft, white, pinkish outgrowths, and in some cases, especially when the pedicle was long, they were deeply congested. It was in this type that "joint mice" or melon-seeds were sometimes found lying in the joint cavity. As a rule only the larger joints were involved and the condition remained stationary.

formation of warty growths of vascular polypi on the synovial membrane. The cartilage was not much altered, but might show signs of atrophy. The bones of the articulation were normal.

The *Infective type* included a group of cases which were usually diagnosed as rheumatoid arthritis, but in which the arthritis was due to some definite micro-organism. A careful inquiry into the history and a study of the cases would occasionally make it possible to determine the type of micro-organism to which the arthritis was due, but more often it was impossible to arrive at a definite diagnosis. Examples of this type were those obscure forms of chronic arthritis due to the gonococcus, pneumococcus, or various types of dysenteric bacilli, and most observers would include streptococci and staphylococci, but he was doubtful if these two latter organisms were so common a cause of chronic arthritis as was usually thought. Clinically the condition might resemble the adhesive type, but a careful inquiry into the history of onset and progress of the disease, together with a study of the clinical symptoms, usually made it possible to give a provisional diagnosis of infection. This type would, of course, drop out of the above classification when methods of diagnosis improved.

Dr. J. A. GLOVER of the Ministry of Health presented the meeting with some very interesting figures, the results of the inquiry instituted in 1921 by direction of the chief medical officer to look into the large amount of morbidity amongst insured persons ascribed to "rheumatism." In this inquiry a number of insurance practitioners in various parts of the country rendered most valuable aid. By their help it was possible to keep a sample population of 90,000 insured persons under review during 1922. It was also decided as a separate inquiry to ask the regional medical officers of the Ministry to record every case of rheumatic disease referred to them. Diseases were classified under nine heads, of which osteoarthritis and rheumatoid arthritis were two. Standards of comparison were arranged. The following table gives the incidence of the condition.

	33 Regional Medical Officers, examining 27,805 male and 39,130 female patients with all diseases, reported in 1922 the following cases:		19 Insurance Practitioners, of 44 practices, representing a panel of 90,891 (57,993 males, 32,893 females), reported in 1922:	
	Males.	Females.	Males.	Females.
Rheumatoid arthritis	364	805	83	57
Osteoarthritis	640	623	119	71
Gout	28	23	150	3
Chronic joint changes (unclassifiable)	23	43	50	23
Total	1,120	1,494	432	191
Percentage of all rheumatic cases	44	53	24	26

Mr. Glover showed a number of most interesting diagrams illustrating these and other figures. The usual idea that the female liability to rheumatoid arthritis was at least three times greater than the male was, on the whole, borne out by Dr. Glover's figures. He made an interesting point in demonstrating the heavy osteoarthritis attack rates, as regards males, in the north-west (Lancashire division) and the heavy gout incidence in the same sex in the south-west and the south-east. In females the south-east showed a very high rheumatoid arthritis incidence.

## GLANDULAR FEVER AND INFECTIVE MONONUCLEOSIS.

At the meeting of the Section of Medicine of the Royal Society of Medicine on April 24th Dr. H. LUTHERY TIDY discussed the possible identity of glandular fever and infective mononucleosis. Dr. Tidy said that glandular fever was an acute infectious disease, principally occurring in childhood and characterized by enlargement of the cervical glands, which, however, were not painful in spite of their size. A child of 6 or 7 years might have several discrete glands almost the size of an egg. The temperature rose with

the enlarging of the glands, and generally reached about 103° F., falling as the enlargement subsided. Suppuration was extremely rare, and, when it occurred, was probably due to secondary infection. The only serious complication was haemorrhagic nephritis. Convalescence was slow, but recovery was almost invariable, and the mortality might be said to be negligible. During the last two years a number of papers had been published on infective mononucleosis, in which condition there was said to be a high percentage of lymphocytes, even as much as 95 per cent. in a total count of 23,000. The clinical description of these cases of infective mononucleosis was indistinguishable from that just given of glandular fever. In 1921 the speaker, with Dr. Morley, having a case of glandular fever, took a blood count; he could not find any record of a blood count having been taken previously in such a case. The result showed 84 per cent. of lymphocytes in a count of 15,000.

Dr. Tidy had had the opportunity also of observing an epidemic of glandular fever in a school at Epsom, where 24 out of 42 boys reported sick with large glands in the neck and sore throat. In none of these cases did the temperature rise above 103°, and in only three cases above 102°. In no case was there suppuration, and in only one case was the spleen enlarged. The fauces were reddened in a good many of the cases and the tonsils enlarged. Some difficulty was experienced in taking blood tests owing to the fear lest it should be thought that the boys were being experimented on, but blood counts were actually taken in 18 cases, and the results, which he showed to the Section, suggested that an absolute lymphocytosis was a general though not an invariable occurrence in glandular fever, but the lymphocytosis might be very transient, very slow of development, and not always present at the onset of the illness. He believed that glandular fever was a clinical entity, and he emphasized in this connexion the size of the glands and the small changes in the fauces compared with the glandular enlargement. The clinical picture of glandular fever was quite characteristic, and sufficient for diagnosis and prognosis. He believed also that glandular fever and infective mononucleosis were clinically identical.

As for associated conditions, Dr. Tidy continued, whooping-cough might be ruled out, because many of the children concerned had whooping-cough before and since the attack; the same argument applied to mumps. With regard to acute leukaemia, it was quite definite that leukaemia was not infectious; an epidemic of leukaemia had never been heard of. He imagined also that it would be possible to distinguish between the blood changes in acute leukaemia and in this condition. The diagnosis from acute leukaemia was easy, and more usually the medical man who saw a case of glandular fever was inclined to put it down to mumps. Another condition for which it was sometimes mistaken was acute tuberculous adenitis; this mistaken diagnosis might have serious consequences for a youth. As to possible confusion with tonsillitis, the changes in the fauces in glandular fever were characteristically very slight, especially so when compared with the marked involvement of the glands.

### Osteo-arthritis of the Spine.

Dr. CLAUDE GOULDESBOUGH discussed osteo-arthritis of the spine, particularly from the radiological point of view. He commented upon the number of cases sent down with a provisional diagnosis of renal calculus which showed no signs of calculus on examination, but did show osteo-arthritis of the spine. In one year, out of 196 cases collected from the wards and out-patient department of St. Thomas's, all of them with a provisional diagnosis of renal calculus, such calculi were found to be present only in 19, while among the remainder 17 showed osteo-arthritis of the spine. Thus there were nearly as many osteo-arthritic spines as cases of calculus. He discussed osteo-arthritic spines in three categories—two completely distinct from each other, and the third a combination of the other two. The first and most common was distinguished by a spikiness or buttressing of the vertebrae, the region most commonly attacked being the dorsal; the second was distinguished by no extraneous deposits, and showed simply erosion of the discs, affecting the lumbar region. He showed a number of radiographs and drew attention to the excess shadow beyond the outline of the true vertebrae in the first type. The definite edge of the vertebrae was clearly seen, and beyond this the overlying fibrocytic condition.

## NON-OBSTRUCTIVE JAUNDICE.

A MEETING of the Liverpool Medical Institution was held on April 12th, with the President, Professor J. HILL ABRAM, in the chair, when Professor R. J. M. BUCHANAN introduced a discussion on non-obstructive jaundice.

He considered that the distinction should be between jaundice without gross obstructive lesion and jaundice from other causes. He held that the condition was always due, in the last event, to obstruction to the biliary secretion, even in cases where the cause was due to an inflammatory condition of the liver. Professor Buchanan reviewed the differential diagnosis and discussed the value of the Cammidge reaction and of the chemical test introduced by van den Bergh. He discussed the difficulty that arose in the diagnosis between jaundice that was purely haemolytic in origin and forms in which there was some functional derangement in the hepatic cells.

Dr. E. CRONIN LOWE said that jaundice was a symptom arising from derangement of hepatic function from many causes. Among the most common was infection of intestinal origin, the infection proceeding by way of the portal circulation. Mild jaundice could also be demonstrated in the early stages of many infections which were not portal. Van den Bergh's test should prove of value in distinguishing between gross obstruction and catarrhal cellular hepatitis. He had not found absence of post-prandial leucocytosis reliable as an indication of hepatic deficiency. All cases of jaundice without gross obstruction required extensive investigation, which included examination of the gastric, intestinal, and urinary secretions, and also of the blood. When jaundice was traceable to portal infection treatment by a vaccine was of considerable value.

Dr. H. PEMBERTON said that apart from a grossly obstructive type of jaundice which showed acholic stools, bile pigments always in the urine, and an excess of bilirubin (giving the direct van den Bergh reaction), as well as of bile salts in the blood, there was another group to which the term "non-obstructive" had been loosely applied. In this group bile derivatives might be normal or in excess in the faeces, bile pigments might be absent from the urine, but urobilin was often present and in the blood there was a form of bilirubin which gave the indirect van den Bergh reaction, but usually no bile salts. Among the many types which comprised this latter group a subdivision seemed possible into a type presenting mainly haemolytic features and a type presenting mainly primary hepatic inefficiency often. In the differential diagnosis of these types splenic enlargement increased fragility of erythrocytes and urobilinuria often contrasted the first type with the second, in which laevulose estimation in the blood after a test meal might show the abnormal curve of liver inefficiency. As a diagnostic test van den Bergh's reaction did not seem of much value in this matter.

Dr. GORDON GULLAN had seen a typical case of nervous jaundice occurring in a student every time he went up for an examination; the jaundice was very deep and lasted for four or five weeks. Dr. Gullan referred to cases of Hanot's cirrhosis, in which, as well as the jaundice and the great enlargement of the liver, haemorrhages were present under the skin and the mucous membranes; in these cases some bile was also found in the stools.

## Cases.

Dr. J. R. LOGAN read a note on an unusual mineral deposit in the soft tissues of the hands, and showed x-ray photographs.

The patient was a female, aged 60, suffering from a mild degree of Raynaud's disease. The hands and feet were always cold, the former often of dusky-blue colour; dilated veins were visible on the face, ears, and tongue. The mineral deposit was not found in the toes. There were many nodules on the sides and palmar surfaces of fingers and thumbs, in the subcutaneous tissue, not specially near joints. Analysis showed that there was no trace of uric acid, and that the substance giving the dense shadows was phosphate and carbonate of lime.

Mr. ARTHUR EVANS read a note on a case of fracture dislocation of the fourth cervical vertebra.

The patient was admitted to the Southport Infirmary under the care of Dr. Reinhardt Anderson, having fallen from a motor lorry. The injury was followed by definite paresis of both upper and lower limbs with sensory phenomena indicating a lesion of the fifth cervical segment of the cord. There was definite tenderness over the region of the fourth cervical spine. A radiograph showed a well marked fracture dislocation forward of the fourth cervical

vertebra upon the fifth below. Expectant treatment was carried out for a short period, but the patient's condition soon became stationary. He was operated on six weeks from the date of the accident, laminectomy being performed, the spines and laminae of the third, fourth, and fifth cervical vertebrae being removed. The cord at the level of the dislocation was found to be greatly indented in its entire circumference by the laminae of the fractured vertebra behind and in front by the "angulation" produced by the body of the vertebra below the dislocation. The patient made a steady and rapid recovery. Twelve months from the date of his injury he was able to resume his ordinary employment as a mechanic in a motor factory, an occupation requiring not only considerable muscular strength but unusual dexterity of the hands and arms.

## METASTASIS IN MUMPS.

At a meeting of the Brighton and Sussex Medico-Chirurgical Society held on April 5th, with Mr. A. J. HITCHCOCK, President, in the chair, Mr. GEORGE MORGAN read a paper on metastasis in mumps. He gave details of the illness of a boy, aged 13, who, during an epidemic of mumps at his school, developed a right parotitis, followed by arthritis of the right knee, delirium, and urticaria. Subsequently he had acute pericarditis with endocarditis, and the urine boiled almost solid, although no casts were found. Next he had symptoms of mitral regurgitation and a right-sided pleurisy, with morbilliform rash and pain and swelling of the right ankle and an enlarged gland in the right axilla. Jaundice supervened with a temperature and pulse rate continuously high, the pericardial friction and the regurgitant mitral murmur still being manifest. Severe pain and tenderness over the abdomen suggested the possibility of acute pancreatitis, and both knees developed an acute arthritis. Blood cultures were sterile. After a prolonged convalescence the boy made a good recovery.

Mr. Morgan also quoted the case of a man of 26 who, while playing billiards, was accidentally struck by the cue on the left testicle. The organ rapidly swelled up and became very painful and tender, and a few days later the left parotid enlarged and the swelling of the testis became reduced. He then had symptoms of meningitis, with severe headache, vomiting, and photophobia. He was very ill indeed, but ultimately made a good recovery. Mr. Morgan thought that possibly the virus of mumps was in the blood at the time, and that the injury caused it to attack the testicle before the parotid.

THE PRESIDENT, Drs. HALL, NEVILLE COX, ALLEN, LIVINGSTONE, and SIMPSON took part in the general discussion which followed, and Dr. MORGAN replied.

## Urological Diagnosis.

Mr. M. FITZMAURICE-KELLY, in a paper on diagnosis in urinary diseases, remarked that a revolution had occurred in surgical urology in the last twenty-five years, due to the new methods of diagnosis which had been introduced and perfected during that time. These methods were chiefly endoscopic, but radiology and chemical physiology had also contributed to the advance. The chief methods employed were discussed in their relation to the main symptoms of urinary disease, and the importance of a diagnosis, as accurate and complete as possible, before treatment was undertaken, was insisted upon. The speaker entered a strong plea for the more careful and thorough treatment of stricture, aided by the information which could be obtained by the urethroscope. In enlargement of the prostate, the importance of a quantitative diagnosis, with special regard to the intravesical enlargement, was urged, and the diagnosis of post-operative obstruction was discussed. With regard to haematuria, Mr. Fitzmaurice-Kelly emphasized the urgency of cystoscopic examination while bleeding was occurring (so that the opportunity of making the diagnosis should not be lost) and the uncertainty of any inference not based on direct observation. Tests of renal function were of great importance in two classes of cases—those, such as enlarged prostate, where the efficiency was in question, and those in which nephrectomy was contemplated, and the functional value of the presumably healthy kidney had to be ascertained. The speaker expressed a preference for the urea concentration test in certain cases, reinforced by the blood urea test in certain cases, and the latter class, especially where operation was necessary to save life, colour tests, used simply as time tests, were of value.

THE PRESIDENT, and Drs. FIELDEN, MORGAN, FITZMAURICE-KELLY, ORLEBAR, and HALL spoke, and Mr. FITZMAURICE-KELLY replied.

## OCCIPITO-POSTERIOR POSITIONS.

At a meeting of the Manchester Medical Society on April 11th, with Sir WILLIAM MILLIGAN (President) in the chair, Dr. DANIEL DOUGAL, in a paper on the diagnosis and management of occipito-posterior positions of the vertex, described the condition as the most frequent complication met with in obstetrics, and suggested that it was responsible for more damage to mother and child than any other single complication. A diagnosis was practically always possible as the result of abdominal palpation, a method of examination to which far too little attention was paid even at the present time; in fact, vaginal examination, he believed, was still chiefly relied upon for the recognition of obstetric difficulties, and the abdominal method was practised in a very perfunctory fashion, if at all. He thought that the left lateral position of the patient was partly responsible for this, as the abdomen was not readily accessible for examination unless the patient was turned over on to her back, and, rather than disturb her, many were content to neglect the method altogether. In the great majority of occipito-posterior cases it was quite easy to feel the child's limbs occupying the front of the abdomen and the narrow plane of the back lying well out towards one or other flank. On vaginal examination an attempt should be made to recognize the sutures and fontanelles and to ascertain the direction of the pinna of the child's ear. In any case of doubt the patient should be anaesthetized and the whole hand passed into the vagina.

As regards treatment, Dr. Dougall restricted his remarks almost entirely to the following three main lines:—(1) Preventive: Cases seen during pregnancy or early in labour should, he said, be corrected by using the padded binder recommended by Buist (BRITISH MEDICAL JOURNAL, November 12th, 1921, p. 782), or by external manual rotation. (2) Expectant: Where preventive methods were inapplicable or unsuccessful Nature should be given a reasonable time to correct the malposition, and this she would do in 80 to 90 per cent. of cases if there was no interference with her. The condition of the mother and child and the progress of the case generally would decide how long this method was to be continued. It was frequently possible to observe the progress of rotation by inspecting the position of the child's anterior shoulder from time to time. (3) Operative: When previous methods proved unsuccessful the child's head should be rotated bimanually and delivery completed with forceps. It was often an advantage actually to rotate the child's anterior shoulder by placing two fingers of the internal hand behind it. Manual rotation might fail if the head had descended low into the cavity of the pelvis, and then it was worth trying to rotate with the forceps. Lamond Lackie of Edinburgh favoured this method in such cases, but laid stress on the importance of not applying traction until rotation had been completed with the forceps and the latter removed and reapplied. Dr. Dougall believed that it was rarely necessary to attempt extraction with the occiput posterior, and yet a very large number of cases were still treated in that way. It was a common occurrence, in his experience, for many of these cases to be admitted to St. Mary's Hospital after unsuccessful attempts at forceps extraction, the maternal soft parts being seriously lacerated and the children often fatally injured. Rotation and subsequent delivery with forceps were usually carried out with such ease that it must be concluded that the method had not been previously attempted. The reason was to be looked for in faulty methods of examination and failure to recognize the malposition as the true cause of difficulty.

## ETIOLOGY OF TUMOURS.

At a meeting of the Royal Medico-Chirurgical Society of Glasgow held on April 20th Mr. JOHN PATRICK and Dr. J. A. G. BURTON demonstrated four cases illustrating—(1) trauma as a factor in the etiology of sarcoma, (2) the transformation of chondroma and granuloma into sarcoma.

The first case was that of a young miner who sustained a blow on the fronto-parietal region, the resulting effused mass being discovered to be a round-celled sarcoma which had formed in six weeks from the time of injury. The same patient had suffered osteomyelitis of the tibia with formation of granulomata in the skin around the bone wound. These were proved on three examinations to be simple granulomata; after treatment by x rays one of the tumours became altered in appearance, and on microscopic examination was found to be sarcoma.

The second case was that of a boy who had for twelve years suffered from a warty growth on the back of the hand. This was removed by carbon dioxide snow, and three months later a definite subcutaneous tumour was found which was proved to be a spindle-

celled sarcoma. There was also in this case sarcomatous infection of the axillary glands.

The third case was that of a lad who suffered from a tumour of the head of the tibia, which was regarded clinically as sarcoma. Examination on two occasions by microscopic section showed this to be a chondroma. The tumour was extirpated, but growth again took place, and the growth was on this occasion discovered to be a spindle-celled sarcoma.

The fourth case demonstrated was that of a boy of 10 years, who exhibited a swelling in the lower end of the femur, which clinically would be regarded as a sarcoma, but which, when a portion was removed for microscopic examination, was discovered to be a myxo-chondroma. The case was exhibited to the Society as one which would require careful examination from time to time lest sarcoma should develop.

Mr. G. H. EDINGTON made a short communication on exostoses of the long bones. Spongy exostosis, while a well known condition, was, comparatively speaking, infrequent; cases resolved themselves into two categories—the solitary and the multiple exostoses, concerning the latter of which there were frequent mentions in surgical literature. The structure of cancellous exostosis was described and its situation on the affected bone. As regards its origin, he referred to Keith's views on the nature of multiple exostoses—namely, that there is a growth-defect of the membrane enveloping the cartilaginous forerunner of the future bone. The cause of this defect is possibly a disturbance in function of the thyroid gland. Mr. Edington thought that localized defect of membrane might be invoked as the cause of solitary exostosis. He then referred to the clinical manifestations presented by individual cases—namely, deformity, hindrance of function, injury from without, and bursitis—and briefly mentioned the operative treatment of the condition. The communication was illustrated by skiagraphic and photographic lantern slides of cases which he had had under observation.

*Diverticulum of the Bladder.*

Mr. J. MILL RENTON made a short communication on a case of diverticulum of the bladder, and showed the specimen. The patient was a man aged 53, whose urinary trouble followed the spraining of an ankle eight months previously. The bladder on examination reached the umbilicus, and there was no enlargement of the prostate per rectum, but there was obstruction to the passage of the instrument about the neck of the bladder. The urine was highly infected. On opening suprapubically an opening behind the left ureter was found which just admitted the forefinger upwards and downwards in front of the rectum. This diverticulum was separated by blunt dissection, and the neck divided and sutured from the outside of the bladder. Recovery was complete. Mr. Renton made remarks upon previous observations on such conditions, and commented upon the value of cystoscopy. The speaker referred shortly to the operative treatment (1) through the bladder, (2) through the peritoneum, and (3) outside the peritoneum.

Dr. H. E. JONES made a communication on "Glycosuria: a theory of its cause." He described his observations on the activities of the "Californian bees" (also known as the ginger-beer plant), and offered a theory as to the cause of glycosuria.

A MEETING of the Section of Obstetrics of the Royal Academy of Medicine in Ireland was held on April 13th, with the President, Dr. BETHEL SOLOMONS, in the chair. Dr. L. CASSIDY showed a specimen of fibroma of the ovary, removed from a woman aged 54, who had had five children, and whose menopause had taken place eight years previously. Dr. SOLOMONS said that fibromata were found in about 2½ per cent. only of all solid tumours of the ovary. The PRESIDENT showed a specimen of adenomyoma of the uterus, removed from a woman aged 38, who had been married six years and was sterile. At a previous operation a growth the size of a grape fruit, which grew from the left cornu of the uterus and was apparently an adenomyoma, was removed; the uterus was left as the woman was most anxious to become pregnant. She did not become pregnant, and at the second operation an obviously fibroid uterus was found, which was removed with tubes and ovaries, a very small piece of the cervix being left. After operation the patient still complained of pain, and as palpation of the cervical stump caused pain this was removed vaginally. There was no adenomyoma in the cervix, but histological examination of the body tumour showed typical adenomyoma uteri. The case was discussed by Dr. J. S. QUINN and Dr. G. TIERNEY. Dr. GIBBON FITZGIBBON then read the report of the Rotunda Hospital, which was discussed by Dr. L. L. CASSIDY, Dr. TOTTENHAM, Dr. R. J. ROWLETTE, and the PRESIDENT.

BRITISH CONGRESS OF OBSTETRICS AND  
GYNAECOLOGY.

## MEETING IN EDINBURGH.

(Concluded from page 723.)

The morning and afternoon sessions on the second day, Friday, April 20th, were devoted to short papers and demonstration of specimens. The chair was occupied by Dr. HERBERT SPENCER.

*X Rays in Inoperable Cancer.*

Dr. HERBERT SPENCER described two cases of cancer of the body of the uterus with secondary growths in the vulva and vagina, which remain free from recurrence five years and four years respectively after hysterectomy and treatment by  $\alpha$  rays and radium.

*Case 1.*—A parous widow, aged 62, with cancer of vulva and annular stricture of the vagina preventing examination of the uterus. The left vulva and inguinal glands (which were healthy) were excised, and the vagina dilated. The growth was found to be a papillary carcinoma of the uterus; cervix fixed (inflammatory). Radium emanation (108 mg.) was applied to the cavity of the uterus for twenty-four hours; abdominal hysterectomy six weeks later;  $\alpha$  rays to abdomen and vulva. No recurrence after five years.

*Case 2.*—A nulligravida, aged 56, with extensive cancer (adenocarcinoma) of the body of the uterus. Vaginal hysterectomy was performed with galvano-cautery. Four months later an ulcerated growth recurred in the anterior vaginal wall, which was deemed inoperable. Radium emanation (100 mg.) was applied. The growth completely disappeared within three months, and there was no recurrence after four years.

*Chorion Epithelioma of the Fallopian Tube.*

DRS. BETHEL SOLOMONS and E. C. SMITH described a case of primary chorion epithelioma of the Fallopian tube. The patient, aged 40, had been married seventeen years and had eight healthy children, the youngest aged 3 years; there had been no abortions. She was admitted to hospital because of continuous haemorrhage since her last period, which had started three weeks before admission. On the anterior vaginal wall, two inches from the vulva, was a tumour the size of a hazel nut, which proved on removal to be a chorion epithelioma. Laparotomy was performed, and a tumour of the same nature as the vaginal growth was found close to the left cornu of the uterus. The whole uterus and adnexa were removed, but two months after operation the patient developed secondary growths in the lungs, and died. The source of the growth it was impossible to ascertain; the patient had never missed a period, and the corpus luteum was that of menstruation.

*Chorion Angioma.*

Dr. GILBERT STRACHAN showed a specimen of placental chorion angioma. The obstetrical history was unimportant, and the condition was only discovered on examination of the placenta. The tumour was situated at one side of the placenta, was  $2\frac{1}{2}$  inches in diameter, and protruded on the amniotic surface. The uterine surface was not involved. Microscopically it consisted of a number of irregular large spaces filled with blood, and with a myxomatous fibrous tissue between. Dr. Strachan expressed the view that local congestion or inflammation could not explain the condition, and that it represented a purely neoplastic formation.

Dr. R. W. JOHNSTONE showed lantern slides of a similar case described by him in 1914. The tumour was lobulated, and each lobule was covered by exuberant chorionic epithelium, while the tissue between the vessels was myxomatous; the entire tumour therefore was composed of purely chorionic tissue. A distinct kink in one vessel leading to the tumour suggested some obstruction in the circulation as a causal factor.

*Treatment of Urinary Incontinence in Parous Women.*

Professor B. P. WATSON read a paper on incontinence of urine in parous women and its operative treatment. Incontinence of urine, he observed, was often associated with cystocele, but frequently occurred without it. It was observed in parous women, and the cause was a sagging downwards of the neck of the bladder from behind the posterior aspect of the pubis rather than weakness of the sphincter itself; it was produced by overstretching of the pubo-vesical layer of the pelvic fascia by the foetal head during labour. It might be prevented by a timely episiotomy. The operation

he described was similar to that employed by Eden and Lockyer for the radical cure of cystocele, except that the first stitch was placed well out and close to the posterior aspect of the pubis. The fascia was thus brought together over the neck of the bladder; catgut was the suture used. The results showed that out of 48 cases 28 were cured, 16 were improved, and 4 were no better. The paper was discussed by Professor DONALD, Mr. BECKWITH WHITEHOUSE, Professor BLAIR BELL, Dr. EDEN, Dr. HAIG FERGUSON, Dr. FITZGIBBON, Professor LOWRY, and Dr. HERBERT SPENCER. Considerable difference of opinion was expressed as to the nature of the bands seen on the deep surfaces of the lateral flaps. Professor BLAIR BELL maintained that they were not fascial, but composed of involuntary muscle, similar to that found in the utero-sacral ligaments. They should undergo involution after labour, and if they failed to do so incontinence was produced. Dr. FITZGIBBON said that in the cases in which operation failed cystoscopic examination revealed a spot of inflammation at the neck of the bladder. Professor HERBERT SPENCER used silk sutures, and maintained that all cases could be cured by proper operative measures. All the speakers, however, were agreed regarding the preventive value of episiotomy.

*Contraction Ring Dystocia.*

Dr. FITZGIBBON read notes on three cases of contraction ring dystocia. The patients had had 4, 11, and 3 children, and in each the labour was unduly prolonged, in one case for over two days. In one case pituitrin was given, and this probably accentuated the condition, although it did not cause it. In each case the foetus presented by the head, which was free above the brim in two cases and in the third reached the outlet. In one case, although forceps could be applied they could not be placed sufficiently satisfactorily to justify delivery of the head from above the brim, and version was decided on. In the other cases delivery was effected by forceps. In the case delivered by version it seemed at first impossible to pass the hand above the contracted portion of the uterus so as to reach the foetal limbs. In one of the cases delivered with forceps the head was brought over the perineum and in the other down to the perineum with ease, but advance then ceased. The ring in each case was closely applied to the foetal neck while the cervix was widely open and hanging loosely round the head. The ring resisted dilatation for some time in each case but then began to relax, and once this started the relaxation proceeded rapidly and delivery was easily effected—in the case of version and in one of the forceps cases—of living infants. The other case was moderately hydrocephalic. The treatment was practically the same in each case and consisted in the application of a steady dilating force upon the contracted ring, in one case by the passage of a hand between the ring and the foetal body and in the others by bringing the foetal shoulders down against the ring by traction on the foetal head. The ring remained unaltered for six or seven or ten minutes and then relaxed. The condition was closely allied to that found in imprisoned placenta, and the behaviour of the uterus what was to be expected in the case of a muscular organ.

The paper was discussed by Drs. LOCHRANE and SHANNON, Dr. HERBERT SPENCER, Mr. WHITEHOUSE, and Professor LOWRY. Dr. Shannon said that with deep anaesthesia and forceps the child often came away, but not always. In such cases craniotomy followed by version was the best treatment. Dr. Spencer advised cleidotomy followed by the application of a weight. Mr. Whitehouse thought that cleidotomy and version would be difficult to carry out, and did not see how craniotomy could be of benefit. Professor Lowry advised the administration of morphine and chloroform, and that no attempt to deliver should be made for half an hour; premature interference merely stimulated an already irritable uterus.

Professor R. J. JOHNSTONE (Belfast) demonstrated by means of blackboard sketches some uses of the continuous catgut suture in gynaecology.

*Short Papers and Demonstrations.*

*Developmental Intersexuality.*—Dr. F. A. E. CREW (Animal Breeding Research Department, University of Edinburgh) in a paper on this subject, said that abnormality of the reproductive system, in which the external genitalia are of an imperfect female pattern and the internal genitalia consist of paired maldescended testes and a double set of structures (male and female) comprising the accessory sexual apparatus was common among mammals and was usually referred to as tubular partial hermaphroditism. It was suggested that the

condition was the result of retardation in the exhibition of the sex hormone in a male. Normally in a male the sex hormone encouraged the fuller development of the Wolffian ducts, inhibited that of the Müllerian ducts, and guided the growth of the urogenital sinus and genital tubercle into scrotum and penis while controlling the parallel development of the testes and the gubernacular apparatus. In the absence of the directing control of the male sex hormone the Wolffian and Müllerian ducts pursued an equal and parallel development, and the urogenital sinus and genital tubercle continued their undifferentiated growth. Later these structures lost their embryonic plasticity, so that, when the sex hormone was elaborated, they were no longer capable of being affected. What was affected were the secondary sexual characters and the sexual behaviour, so that at the time of sexual maturity the individual had to be regarded as a male.

Dr. HERBERT SPENCER showed a specimen of congenital deformity of the posterior lip of the cervix in a virgin aged 52. The lip was elongated and hypertrophied, so that from base to tip it measured  $2\frac{1}{2}$  inches in length, forming a reddish lobulated tumour which filled the vagina and bulged the intact hymen. There was hypertrophy of the supra-vaginal cervix. Microscopically the tumour consisted of fibrous and muscular tissue covered with stratified epithelium and containing glands lined by a single layer of columnar epithelium. Dr. Herbert Spencer also demonstrated Dr. Butterfield's photo-micrographic attachment to an ordinary camera for taking photographs of microscopic slides without the use of a microscope. Magnification could be obtained up to 35 diameters.

Dr. HAIG FERGUSON showed: (1) A uterus fifteen days after Caesarean section from an eclamptic patient who had died from cerebral haemorrhage. The scar was invisible to naked-eye and even to microscopic examination. (2) An adenomyoma of the posterior vaginal wall simulating epithelioma. (3) Large subperitoneal fibroid with severe intraperitoneal haemorrhage from a ruptured vein on the surface. (4) Adenocarcinoma of the cervix in a nullipara. (5) Utero-vesical fistula plugged by the cervix; a vesico-vaginal fistula had formed during delivery of her sixth child, and after several unsuccessful attempts to close the opening a surgeon plugged up the opening with the uterus. The patient menstruated through the bladder, and by careful hygiene, washing out the bladder twice daily, etc., she had comfort for two years. Calculous deposits then began to form inside the bladder, on the lips of the cervix, and on clots of menstrual blood. These had to be removed every six months. The calculi set up bladder ulceration which resulted in the formation of several small vesico- and urethro-vaginal fistulae. The patient died nine years after operation of an ascending infection of the kidneys and Fallopian tubes.

A lively interchange of views on the best suture material for use in cases of vesico-vaginal fistulae took place between the Chairman and Professor Blair Bell; the former declared that if silver wire sutures were used every case could be cured; the latter that the use of silver wire was a retrograde step and that only catgut was justifiable. He did not claim to cure every case, however, as Dr. Herbert Spencer said could be done if silver wire were used. The silver wire sutures were removed afterwards.

Professor B. P. WATSON showed a uterus with a perfectly healed scar after Caesarean section. The patient had had Caesarean section performed in the South of England three years ago. Convalescence had been febrile, and, fearing the condition of the scar, Professor Watson decided to do a second Caesarean operation, although there was no pelvic contraction; the uterus was removed, leaving the ovaries. The scar had healed perfectly, and no trace of it could be found even microscopically. He had made inquiries regarding the suture material used, and found it had been interrupted catgut inserted through the entire depth of the wound except the mucosa. The wound had then been covered by a Lambert suture. It did not therefore hold that a febrile convalescence was necessarily followed by a weak scar, or that the dictum "Once a Caesarean, always a Caesarean," was always true. Professor Watson then demonstrated Cullen's sign of ruptured ectopic pregnancy in an old scar after an operation for appendicitis. The general opinion of the members was that the sign was of little or no value, the umbilical pigmentation being rarely present, and probably a mere coincidence when it was.

Mr. BECKWITH WHITEHOUSE showed a specimen of cervical fibroid with a vein opening into the cervical canal; severe haemorrhage and collapse had occurred after a fit of coughing;

myomectomy, followed by hysterectomy, was successfully performed.

Dr. O. D. LOCHRANE described a case of endometrial adenoma of the abdominal wall following ventro-suspension three years before. The tumour lay in the right rectus sheath, was more than half the bulk of the corpus uteri, and on section was found to contain a large number of small cystic spaces containing dark fluid blood, lined by columnar or flattened epithelium and surrounded by a stroma-like mantle. The tumour became enlarged and tender during each menstrual period. The body of the uterus was found connected with the site of operation scar by a peritoneal band one and a half inches long. The right ovary was adherent and contained several haemorrhagic cysts. Dr. Lochrane believed that the tumour had arisen from an implantation of endometrial tissue, carried by the catgut sutures passed between the uterus and abdominal wall at the first operation.

Dr. R. W. JOHNSTONE read notes of a case of endometrioma of the posterior vaginal wall associated with "chocolate cysts" of the ovary. The chief symptoms had been intra-menstrual dysmenorrhoea, dyspareunia, and sterility. Several speakers objected to the term "endometrioma" as unnecessary. "Adenomyoma" was sufficient. Mr. WHITEHOUSE related a case exactly similar to that described as "endometrioma" in an appendix scar in a male. Professor BLAIR BELL, however, maintained that the term "endometrioma" expressed the function of the small glands which rest in an endometrial stroma and also menstruate; an adenomyoma did not menstruate, and endometriomata were never found before puberty.

Dr. JAMES YOUNG showed lantern slides of an early ovum calculated to be about fourteen or fifteen days old. The blastocyst showed no projection of mesoderm into the trophoblast, and the trophoblast, unlike the Teacher-Bryce ovum, consisted almost entirely of cells of the Langhans type.

Dr. F. J. BROWNE (Edinburgh) read a short paper on some problems of latent syphilis, and also demonstrated a specimen of congenital absence of the left half of the diaphragm in a foetus.

This concluded the proceedings, and the members were afterwards entertained to tea in the reception room of the Royal College of Surgeons.

## Reviews.

### THE MECHANICS OF THE DIGESTIVE TRACT.

It might be said that the plausibility of a hypothesis varies inversely with the number of suppositions on which it is founded. The fewer the assumptions required to support it, the more likely is it to be correct. The aim of all biologists is to make use of as few hypothetical factors as possible in working out a reasoned explanation of observed facts. History shows frequently how the earlier hypotheses regarding any phenomenon tend to be complicated and involved, and how gradually, as more and more comes to be known of that phenomenon, one by one the unnecessary assumptions are pruned away, till ultimately the whole series of facts is found to be capable of explanation on the basis of one general fundamental law. Simplification is the essence of wisdom. The truth of these remarks is well exemplified in a book by Dr. ALVAREZ, entitled *The Mechanics of the Digestive Tract*,<sup>1</sup> in which he has collected and summarized the numerous contributions he has made during the past few years to the physiological journals. Instead of being content with the vague general concepts of vagotonia and sympathicotonia, instead of invoking the autonomic nervous system as the primary cause of intestinal movements, he has studied the reactions of the actual muscle itself, and has found in it certain properties which are sufficient to explain a large number of phenomena hitherto generally supposed to be dependent on the action of extraneous and more complicated factors.

Evidence is first brought to show that the circular muscle of the intestine is able to contract—and to contract rhythmically—after being deprived of all nerves. The stimulus giving origin to the beat is in the muscle itself. Dr. Alvarez tells us, moreover, that strips of muscle removed from different portions of the small gut show variations in rhythm. For

<sup>1</sup> *The Mechanics of the Digestive Tract*. By Walter C. Alvarez, M.D., George Williams Hooper Foundation for Medical Research, University of California. New York: Paul B. Hoeber. 1922. (Demy 8vo. pp. xii + 192; 22 figures. 3.50 dols.)

instance, the duodenal muscle contracts twenty times a minute, that at the lower end of the ileum only ten times a minute. The ratio of rhythmic contraction in the small intestine varies inversely as the distance from the pylorus. A definite gradation in rhythm is seen on passing down from the upper to the lower parts of the gut. But there are other gradients noticeable besides the rhythmic gradient. On comparing the duodenal muscle with the muscle of the lower ileum Dr. Alvarez has found that the latent period in the former is shorter, that its tone is greater, that its tendency to beat when removed from the body and placed in warm oxygenated Locke's solution is greater, and that its irritability to distension by gases also is greater than in the case of the latter. Further examination shows that the output of carbon dioxide is higher in the duodenum than in the ileum, and that the catalase content of the muscle is likewise greater. There is, in fact, a distinct parallelism between the gradients of rhythmic contraction, production of carbon dioxide, and catalase content. In other words, the metabolism of the upper part of the bowel is more rapid than that of the lower, and there is a graded difference between the two. Stimulate the small gut at any one point, and a wave of contraction spreads out in both directions, but because of the higher resistance of the cephalic segment and the lower resistance of the caudal segment the wave is more marked and travels farther in the downward direction.

All this is physiological. Under diseased conditions alterations in the various gradients arise leading to reversed peristalsis and other disturbances of contraction. It is these—a description of which unfortunately would take too long to give here—which are so interesting from a clinical point of view. Reasoning from ascertained fact the author uses his gradient theory to shed light on the most diverse conditions, such as indigestion, constipation, intestinal obstruction, vomiting of pregnancy, dietetics, the action of drugs, and other subjects which should claim the attention alike of the physician, the surgeon, and the gynaecologist. It is a wide, comprehensive, and illuminating theory. It is advanced in no spirit of dogmatism but with the caution of an experienced scientific worker; and no claim is made as to its finality.

The book will be widely read and widely appreciated. It is both helpful and stimulating. It is provided with an excellent bibliography, containing 456 references to original papers—altogether invaluable to those engaged in research. We will not add more to the list of reasons why it should be read. We recommend it unhesitatingly to all interested in the physiology and pathology of the animal body.

### DISEASES OF CHILDREN.

DR. J. H. HESS'S *Principles and Practice of Infant Feeding*, first published in 1918, has now reached its third edition.<sup>2</sup> It is smaller than many books devoted to this difficult subject, and on that account is somewhat easier to read, though perhaps not less difficult to understand. Dr. Hess is of the Czerny-Finkelstein school; but while still following that teaching and classification, he has in the present edition adopted some new names. He now divides the nutritional disturbances of infants into those unassociated with diarrhoea, those characterized by diarrhoea, athrepsia, and anhydraemia. But these new words are only other forms of Finkelstein's terms, disturbance of balance, dyspepsia, decomposition, and intoxication; and they only add to the artificial complications of the subject. Our real knowledge of dyspeptic infants is at present hidden under a mountain of prodigiously long names, which are worthy of the ingenuity of mediaeval theologians. These names do not accurately describe clinical phenomena, nor do they succeed in grouping them into a satisfactory pathology. As for therapeutics, though the ingenious but hypothetical pathological conceptions introduced by the German schools of Czerny-Finkelstein have strongly influenced treatment, yet it should be recognized that the method is empirical; not the wise and safe empiricism founded on experience and clinical observation, but that which rests on pretty but unsubstantial pathological theories. Dr. Hess gives most careful and detailed accounts of treatment, but does not record a single case illustrating its results; he, indeed, shows two charts, one labelled by decomposition, the other lobar pneumonia complicated by enteritis; but without more clinical details they are of little value. Some chapters are also devoted to rickets, spasmophilia, scurvy, acidosis, and the anaemias of infancy. The

author deals at length with the various theories of origin of rickets, with recent experimental work, with morbid anatomy and chemistry, but very summarily with the clinical features. Fig. 15 is a photograph of "a colored infant" showing marked rickets; Fig. 17 is given as a radiograph of the wrist of the same infant, but the ossification of the carpal bones is of a stage much later than infancy and would indicate an age of at least 5 years. The book concludes with an appendix of formulae and other miscellaneous information.

The book on diseases of children by Professor E. FEER of Zürich was first published in 1911; it has now reached its seventh edition. The author obtained the co-operation of a number of Austrian and German authorities, including von Pirquet, Pfäundler, Finkelstein, Moro, and Meyer. A book entitled a *Textbook of Pediatrics*,<sup>3</sup> founded upon Feer's volume, which was written in German, has now been produced in English by Drs. SEDGWICK and SCHERER. To it there are nine German contributors and fifteen American, and it is not quite clear how far the work of the latter is faithful translation and how much is revision and alteration. The general plan and main divisions remain as in the German book, and as it includes within its nine hundred odd pages a long section on infectious diseases and another on diseases of the skin the book cannot be described as too big for its scope. The number of illustrations is large (262), and some of those in the section of skin diseases are particularly clear and good; on the whole, however, the quality of the photographs is disappointing. There is also a tendency to a too literal translation, resulting in a clumsy form of German-English: for example, "the tendency is familiar" (p. 214); "a form of rheumatic disease coordinial with the joint inflammations" (p. 551); "rheumatism nodosum" (p. 709); "grippal diseases" (p. 699); "a plotic liver" (p. 323). Actual mistakes are also too numerous: on page 505, atheosis should be athelosis; and in the account of rickets there is a reference to *Findley's* observations (Findlay). Throughout the book there is very little said about the teaching and contributions of the British schools of medicine, and the book must be regarded as presenting a German view of the subject. For example, in reference to the vitamin theory of rickets, the following sentence occurs: "While the theories about this factor have formerly been rather vague, American observers in animal experiments, and pediatricians in the central empires, during the food shortage caused by the blockade have added considerable research to this view."

*Feeding, Diet, and the General Care of Children*,<sup>4</sup> by Dr. A. J. BELL, is a book whose title reveals its general character. It is written for mothers and trained nurses, and describes in simple language the rules of infant feeding, the preparation of bottles, the hygiene of the nursery, and so forth. It discusses also the diet of older children, supplying diet lists up to twelve years of age. Other chapters are devoted to very short accounts of the symptoms and nature of the commoner diseases of infancy and childhood. Such a book is apt to recall the old saying that "a little knowledge is a dangerous thing"; and while it could do no harm in the hands of a trained nurse it might not be harmless in those of the average mother. The aim of the book is praiseworthy, and the simple, clear style is well adapted to achieve it.

Dr. WALTER BIRK's book on diseases of infants is a companion volume to that on diseases of children, already noticed. The present volume is the fifth-sixth edition,<sup>5</sup> the first having appeared early in 1914. The book seems popular in Germany, and translations have been published in American, French, and Italian. In trying to explain this success, one is struck by the small size of the book; the physiology and feeding and diseases of infants are dealt with in 275 pages. As it is written expressly for students and practitioners, this brevity gives it an advantage. There are four sections, dealing with the dietetics of infancy, the diseases of the newborn, the

<sup>2</sup> *Textbook of Pediatrics*. Edited by Professor E. Feer, Zürich. Translated and edited by J. P. Sedgwick, B.S., M.D., and C. A. Scherer, M.D., F.A.C.P. First edition in English. Philadelphia and London: J. B. Lippincott Company. 1923. (Med. 8vo, pp. xviii + 917; 72 figures, 42s. net.)

<sup>3</sup> *Feeding, Diet, and the General Care of Children. A Book for Mothers and Trained Nurses*. By Albert J. Bell, A.B., M.D. Philadelphia: F. A. Davis Company. 1923. (Post 8vo, pp. xii + 275; 11 illustrations, 24s. net.)

<sup>4</sup> *Säuglingskrankheiten*. By Professor Dr. Walter Birk. Fifth and sixth editions. Bonn: A. Marcus and E. Weber. 1921. (Demy 8vo, pp. xii + 282; 25 figures.)

<sup>5</sup> *Principles and Practice of Infant Feeding*. By Julius H. Hess, M.D. Third revised and enlarged edition. Philadelphia: F. A. Davis Company. 1922. (Demy 8vo, pp. xvi + 495; 34 figures. 4 dolls. net.)

nutritional disorders of infants, and the diseases of infants. Following the classification of Czerny and Keller, the author divides nutritional disorders into food injuries, infections, constitutional disorders, and congenital defects. As is common in German textbooks, he gives a full description of the exudative diatheses of Czerny. This section is well done, and the principles of treatment are fully explained without excessive detail. The section dealing with diseases of infants is perhaps abbreviated to a dangerous point; but there is an adequate account of congenital syphilis, and also of the common respiratory disorders of infants. The description of nervous diseases is pressed into six pages, and is quite inadequate.

### TREATMENT OF FRACTURES.

THE ninth edition of *The Treatment of Fractures*,<sup>6</sup> by C. L. SCUDDER, has recently been published. The book is now so well known that it is no exaggeration to say that it is the standard American work on the subject. Since the appearance of the eighth edition in 1915 an enormous number of cases of fracture have been under treatment as the result of the war. Experience gained from these cases has to a certain extent modified surgical procedure, for the principles of treatment are the same in civil as in military surgery. It has come to be generally recognized that a fracture is not only a lesion of bone, but may also be associated with injury to the skin, muscles, blood vessels, nerves, and to joints in the neighbourhood of the fracture, as well as to the several viscera protected by bony structures. Treatment to be efficient must be directed not only to procuring accurate union of fragments, but to the restoration of the surrounding soft parts. Perhaps some of the outstanding advances in the treatment of fractures may be summed up as follows: The need for immediate operative treatment on all cases of compound fracture, with removal of damaged tissues and efficient fixation. The proper treatment of shock. The acknowledgement that the indirect and direct traction principle is capable of correcting shortening in fractures of long bones, and that the cases in which direct fixation by the use of metallic sutures and plates is indicated are relatively few. The necessity for the early active movements of joints contiguous to the fracture. The value of active as distinguished from passive movements of joints. And lastly, the absolute necessity for x-ray examination of fractures both before and during treatment.

Throughout his work Dr. Scudder pays attention to the prognosis in the various forms of fracture, and a clear guide is given as to the probable period of disability. The book is most admirably printed and fully illustrated, with x-rays, diagrams, and photographs which greatly add to its value.

Cases of so-called simple fracture are often dreaded by the general practitioner and surgeon alike, and the result is frequently highly unsatisfactory from the patient's point of view. The book under review should prove of real help in the treatment of these difficult problems, and can be strongly recommended.

### ST. MARY'S HOSPITALS, MANCHESTER.

THE *History of the St. Mary's Hospitals, Manchester*,<sup>7</sup> prepared by Dr. J. W. BRIDE, is based on an analysis of the early registers showing the obstetric work of the hospitals. In the course of that undertaking he learned much of interest concerning the early history of the institution, and decided to make it accessible to others. The result is a concise, clearly expressed account of the hospital since its foundation. It contains chapters on the administration and management of the institution and its gradual development, with a series of short biographies of twenty-one former honorary physicians and surgeons. A list of all the honorary members of the staff who have been connected with the hospital since it was first established is given in an appendix. Within the limits to which he has confined himself Dr. Bride has done the work well and, as far as we can judge, accurately. The present charity, known as the "St. Mary's Hospitals," consists of a handsome modern building with 121 beds adjoining the Royal Infirmary, devoted exclusively to gynaecology and diseases of children, and another equally modern building

of 58 beds with 50 babies' cots for the reception of maternity cases, situated more in the centre of the town. It was formed in 1904 by the amalgamation of the old St. Mary's Hospital for women and children with the more recently established Southern Hospital, also for women and children.

The older institution, known since 1854 as St. Mary's Hospital but originally designated "the Manchester Lying-in Hospital," was founded by Mr. Charles White, F.R.S., in conjunction with his son Thomas and his friends Drs. Edward and Richard Hall in the last decade of the eighteenth century, a century prolific in the establishment of medical charities, which have survived to the present day. It is interesting to note that with the exception of St. Bartholomew's at Rochester, dating from 1078 A.D., and the Bath Mineral Water Hospital, from 1610 A.D., the eighteenth century opened apparently without any provincial hospitals. Addenbrooke's Hospital, Cambridge, was founded in 1719; between 1735 and 1750 six more came into being, and by the end of the century the number had been increased by thirty-one more, of which ten were established in the last decade. St. Mary's Hospital, opened in May, 1790, was in point of age the second lying-in charity in the provinces; the Newcastle-on-Tyne Maternity Hospital was established in 1760 and the Liverpool Maternity Hospital in 1796. Its first habitation was a small house, from whence it was transferred to more commodious premises, and in 1855 to a building especially erected for the purpose in Quay Street. Finally, the present building in Whitworth Street, now used for maternity cases only, was opened in 1903. The development of the hospital presents some points of interest. It was originally designed for lying-in patients only; a considerable number were admitted for their confinements, but most were attended at their own homes. The scope of its work was gradually altered; fewer and fewer cases were admitted as in-patients, until in 1816, partly from inadequacy of funds and other reasons, all patients were attended at their own homes. Coincident with this diminution in the maternity in-patients there was developed an out-patient department for "all diseases peculiarly incident to women, and to children under two years." Some years later in-patient accommodation was provided for difficult maternity cases and also, with the advance of gynaecology, provision for diseases of women in general. Amongst the twenty-one short biographies of former members of the staff the first place is naturally given to Charles White, the founder of the hospital, a remarkable man and a picturesque figure; lack of space, and no doubt the fact that his career has been amply treated elsewhere, have prevented Dr. Bride from doing full justice to him. He was 62 years of age when he founded the hospital; he had long been distinguished as a general surgeon, and, as an obstetrician, had revolutionized the management of lying-in women. Without a knowledge of the conditions of life at that period, it is difficult to appreciate the originality to conceive, and the energy and force of character required to enforce, the line of treatment he introduced.

In this connexion it may help a little to remember that White must have worked under conditions and in surroundings similar to those depicted by Hogarth, for they were contemporaries, though Hogarth died in 1764, when White was 36. In 1752 White had been instrumental in founding the Manchester Royal Infirmary and was an active member of the staff for thirty-eight years, when, owing to a dispute with the board of management, he resigned and took part in the founding of the maternity hospital.

Dr. Bride does not make any adequate reference to the Southern Hospital, which was an integral part of the present St. Mary's Hospitals. It was established about 1866, through the exertions of Dr. John Thorburn, a man of great public spirit and high repute, who was Professor of Obstetrics and Gynaecology at the Owens College, which became later the Victoria University of Manchester. It was founded as a hospital for diseases of women, including maternity cases, and children. On the death of Professor Thorburn, Dr. W. J. Sinclair became the leading surgeon there, and when he succeeded to the professorship of obstetrics and gynaecology the hospital became closely identified with the university. In 1893 the David Lewis Trustees offered £70,000 to build a new joint teaching hospital on a site near the university, on the condition that the two institutions were amalgamated and that the university participated in the control of the new hospital. The scheme fell through, owing to the inability of those concerned to come to a satisfactory agreement, and the money was used to found the David Lewis Epileptic Colony at Sandalebridge, Cheshire. Ten years later, conditions having

<sup>6</sup> *The Treatment of Fractures, with Notes upon a few Common Dislocations.* By C. L. Scudder, M.D. Ninth edition, revised. Philadelphia and London: W. B. Saunders Company, 1923. (Roy. 8vo, pp. 749; 1,252 figures, 42s. net.)

<sup>7</sup> *A Short History of the St. Mary's Hospitals, Manchester, and the Honorary Medical Staff, from the Foundation in 1790 to 1922.* By J. W. Bride, M.D. Manchester: Sherratt and Hughes, 1922. (Cr. 8vo, pp. 132; 10 plates, 6s.)

altered, the amalgamation was successfully carried out with other funds. All these matters are briefly noted in the book in a manner that excites interest and makes the reader wish that the author had been a little less concise. We would especially have liked to know more about Dr. Clay, the Father of Ovariectomy in this country.

#### ABDOMINAL PAIN.

DRS. WILLIAM BRAMS and ALFRED LUGER, who have translated Professor NORBERT ORTNER's book on *Abdominal Pain*,<sup>8</sup> state that the teachings of Bamberger, Neusser, and Ortner are presented in it. We regret that they are not expressed more clearly, though we suspect that the translators are in some measure to blame. The headings of the chapters are well chosen—diffuse abdominal pain, localized abdominal pain, epigastralgia, pain in the right hypochondrium, and so forth—but the promise of orderly information held forth is not fulfilled in fact; there is too much repetition and too much confusion. There are a few good points—such, for instance, as the fact that in intestinal colic pain is of a wave-like character, rising to a maximum and then subsiding with more or less complete relief until the next wave comes. In biliary and urinary colic, on the other hand, the pain is continuous, perhaps for hours, with only slight variations in intensity. On the whole only a skilled clinician will gain anything from the book, as only such a one will know how to separate the plums from the vast amount of pudding in which they are embedded. An extract from page 51 will give an idea of the author's catalogue-like method. He is speaking of the abdominal crises of tabes, and goes on to say "such crises may be due to causes other than tabes—as, for instance, spinal lues, syringomyelia, multiple sclerosis, myelitis, diabetes, Basedow's disease, tuberculosis, syphilis, neoplasms, actinomycosis of the intraspinal roots, chronic morphinism, disease of the coeliac plexus, pancreatitis, lesions of the lesser curvature of the stomach or of the cardia, retroperitoneal glands, and aneurysm of the abdominal aorta."

#### SURGERY.

THE appearance of the fourth fascicule of *La Pratique Chirurgicale Illustrée*,<sup>9</sup> by VICTOR PAUCHET, brings out in many ways the contrast between English and French methods. The volume is well got up and there are numerous illustrations depicting the minutiae of each step in the operations. It deals with a variety of subjects. For example, M. Pauchet tells us that he treats recurring dislocation of the shoulder-joint by excision of a portion of the lax posterior part of the capsule. The arm is abducted to a right angle and the skin incision is made in the axilla along the line of the neurovascular bundle, which is retracted forwards. For a surgeon possessing the necessary anatomical knowledge the operation is said to be simple. The author accepts the view that adenomata of the breast and chronic mastitis are due to chronic intestinal stasis. In all doubtful cases of malignancy he strongly advises local excision followed by microscopical examination; the radical operation, should it then be found necessary, being deferred until a later date. He considers this step essential, not only for establishing the diagnosis, but also the prognosis. What happens to the lymphatic spread following this intervention, should the tumour be malignant, is not discussed, and the method can be hardly said to be an advance on that of rapidly cutting a section by means of the freezing microtome and examining it at the time of the operation. The radical operation recommended follows the usual lines, except that the incision does not go so low; mention is not made of the lymphatic spread along the rectus sheath. He considers two applications of radiotherapy before operation useful. Of cases of duodenal ulcer treated by gastro-enterostomy he says that 70 per cent. are completely cured, and that 30 per cent. suffer from after-trouble, including hæmorrhage, perforation, and jejunal ulcers (5 per cent.). Catgut is used throughout in the form of three rows of sutures. A transverse incision is advocated as giving good approach and a means of exploring the gall bladder, appendix, and looking for signs of stasis. In an article on the biliary tract its physiology and its relations to the pancreas, as well as the formation of gall stones, are discussed; the gastric content was found to be normal in the majority of cases of gall stones. For carcinoma of the

caecum right hemicolectomy with end-to-end anastomosis is performed. For carcinoma of the rectum he advocates permanent colostomy followed in fifteen days by the application of radium and in six weeks by excision of the lower bowel by the abdomino-perineal route. For fibrous contraction of the rectum temporary colostomy is performed followed by perineal excision and reconstitution of the bowel. This is no doubt the ideal method, but the author does not say in what percentage of cases it is possible.

#### NOTES ON BOOKS.

UNDER the title of *Puerperal Sepsis and its Prophylaxis* Dr. THORP, the Assistant-Medical Officer of Health for Sunderland, and Borough Medical Officer for Maternal and Child Welfare, has summarized a good deal of clinical knowledge of the condition named, and indicated the treatment he has found useful in his official practice. The most valuable part of his short book is the section on prophylaxis, especially as bearing upon the management of maternity homes. His recommendations include the daily inspection of the fingers of the midwives and pupils by the matron, and he emphasizes the doctrine that the value of soap and water is much greater than that of antiseptics for the hands. "Too much reliance is placed upon the perfunctory use of antiseptics by pupils and midwives, sufficient time for action of these being rarely given." He might have added also that the strength which most skins can tolerate is quite inadequate for the purpose of the destruction of organisms. It is high time that this fetish of a bowl of 1 per cent. lysol or other similar solution should be abolished. The author says:

Surgical obstetrics should never be carried out without an anaesthetist. It is impossible to administer chloroform and to apply forceps and remain sterile.

There is room for more specialists in midwifery in great industrial areas. Too often surgical procedures of grave import have to be undertaken by practitioners with little experience and with less liking for the work and with totally inadequate help.

A very much improved training of midwives is required, with particular supervision of the training afforded in small maternity homes.

The above quotations may suffice to indicate the lines upon which Dr. Thorp deals with this question of prophylaxis; their value, and indeed the value of the whole pamphlet, is enhanced by its being written by one who is not himself an obstetric specialist. We trust it will have a wide circulation, as a perusal of it cannot fail to be helpful and instructive alike to medical practitioners, public health officials, and nurses.

The fourth quarterly volume of *International Clinics*,<sup>10</sup> edited by Dr. HENRY CATTELL of Philadelphia, in collaboration with several distinguished members of the profession in America, the British Isles, and Canada, contains a number of illustrated clinical lectures and original articles dealing with medical welfare work, nutritional problems, clinical medicine, surgery, and pediatrics. In an article on diphtheria Dr. Parker Hitchens of Washington at once gives an estimate of the value of the Schick test; he found that the percentage susceptibility to infection between the ages of 1 and 2 years was 70, and that there was a gradual decline to 15 per cent. over the age of 10 years. In cases where the test is positive and there is a history of definite exposure, an immediate injection of antitoxin should be given. In other circumstances the injection of toxin-antitoxin mixture as a prophylactic measure has been of the greatest value in raising immunity. He states that the annual number of deaths from diphtheria in America was formerly 80,000. Since the use of antitoxin the number has fallen to 20,000, and by the routine application of the Schick test the number should, he thinks, be further reduced. The method should, he thinks, be more widely used for dealing with carriers in schools and children's hospitals.

A German version, apparently much shortened (but it has no table of contents, no index, and no list of illustrations), of Dr. PARKES WEBER's book, *Aspects of Death*, has been prepared by EUGEN HOLLÄNDER under the title *Der Tod als Bild*.<sup>11</sup> The illustrations selected for reproduction are well printed and the book in its German form makes a very agreeable appearance. The full English edition was reviewed in our columns of July 1st, 1922 (p. 16).

## MEDICAL AND SURGICAL APPLIANCES.

*A Pelvic Support for Plaster Bandaging.*

MR. E. MUIRHEAD LITTLE, F.R.C.S. (London), writes: In the applications of plaster-of-Paris to the pelvic region and upper parts of the thighs, as in the treatment of congenital dislocation of the hip, or after operations upon the hip-joint and upper end of the femur, a good support is a desideratum. Such a support should interfere as little as possible with the application of bandages; the part included by them should be as small and thin as possible, and it should be easy to remove the support after the application is complete. The appliance shown in the accompanying illustration

represents an attempt to fulfil these conditions. It was made according to my design for use at the Royal National Orthopaedic Hospital some ten years ago, and has been in general use ever since. The one size of support can be used for almost any sized patient, including infants and adults. The smaller the patient the smaller the part of the support included in the plaster. The whole of a small child's trunk can be supported by it, but in the case of an adult sandbags or some other prop under the shoulders are necessary. Having proved the usefulness of the appliance by a long trial I feel justified in recommending it to all surgeons who may have to apply gypsum to the pelvic region. I am indebted to the makers, Messrs. Krobne and Sesemann, for the illustration.

*The Disinfection of Water-Closets.*

The practice of disinfecting water-closet pans is considered by some persons as entirely unnecessary, for they maintain that if the fittings are properly fixed and the contents of the pan are speedily discharged down the soil pipe with a good flush of water disinfection must be superfluous. On the other hand there are many who will not be satisfied unless a disinfectant in some form accompanies each flush from the cistern. For the use of these an automatic appliance called the Lewbart Disinfecter has been devised, which is fixed on the wall, and arranged that each time the contents of the pan are flushed, five drops of a concentrated disinfectant are poured into the pan and soil pipe after the flushing is completed. The disinfectant container, it is stated, requires refilling about every three months. It is claimed that the apparatus, which costs 35s., can be fixed by an unskilled person. It is obtainable from the Lewbart Manufacturing Company, Ltd., 2 and 3, Norfolk Street, Strand, London, W.C.2.

## RECENT ADVANCES IN MEDICAL EDUCATION IN ENGLAND.

## SECOND MEMORANDUM BY SIR GEORGE NEWMAN.

*[Second Notice.]*

## THE CLINICAL STUDY OF MEDICINE AND SURGERY.

SIR GEORGE NEWMAN begins this section of his Memorandum by affirming that "the purpose of the medical curriculum is the training not of specialists but of general medical practitioners," but complete knowledge of the science and art cannot be attained in five years, and if this be attempted "the curriculum becomes too heavy and the student is overfed for his size." At his school and hospital the student must be taught clinical methods and the clinical habit, including methods of examination, elucidation of subjective symptoms, laboratory tests, case taking, and record keeping. The Medical Council's new scheme is designed to prevent the student from dropping a subject so soon as he has passed in it; the basal subjects will be continued in their application throughout the course. And the student must learn to treat persons as well as diseases: work, sleep, exercise, dietary, recreation, and so forth, have all to be thought of; also public facilities in the way of clinics, dispensaries, hospitals, etc., have to be borne in mind. When he begins practice he is in a new world, with 60 per cent. of the deaths due to half a dozen conditions, and a third of his insurance patients suffering from bronchitis or dyspepsia, another third from minor injuries, lumbago, debility or anaemia, local sepsis, or the

like; there are also defects of the organs of special sense, and notifiable diseases.

A discussion of a minimum standard of competency is illustrated by references to surgery summarized under eleven headings, too long to set out here. The British course of clinical study is set forth by quoting the new regulations of the General Medical Council as officially summarized; the "British method" is described as consisting of (a) clerks and dressers, (b) bedside teaching, (c) clinical lecture demonstrations, (d) clinical teaching in the out-patient department, (e) clinical work in various special hospitals, and (f) junior house appointments. Sir George Newman holds that "it is the pursuance of this system of clinical study which has made English medical education the most practical in the world," and that the Medical Council's action "cannot fail to fortify it and make it more nearly universal."

The chief needs of clinical study are held to be three: "First, the inspiration of all clinical study by science; secondly, an increasing opportunity for the student before qualification to undertake responsible practice under supervision; and thirdly, the permeation of clinical work with a preventive spirit." The author considers that the introduction of the student to the bedside, either under the old apprenticeship system or in the medical school, notwithstanding its common sense, "has brought with it a certain measure of routine and habit which has led to some failure to establish his practice (which has been static) upon his science (which has been progressive)," with the result that "a false antithesis has become current between the scientific man and the practical man." Clinical teaching, it is said, may be so didactic and matter of fact as to fail to awaken mental endeavour, and may be "standardized to the lowest mentality of the student group rather than to the highest." But the teacher should also be leader, "and the students must bestir themselves and climb up after him." Especially in the out-patient department there is risk of "spotting" cases rather than apprehending them. The case, it is insisted, "must be explored by science, system by system, symptom by symptom." Practitioners "may not, it is true, always be able to practise their profession with this degree of completeness and penetration, but they will by this method of education have learned the scientific approach." This the practitioner may acquire "by observation of signs and symptoms with his own eyes and ears and hands and understanding; then by the uses of instruments of precision; then by directly recording his results; then by experience." The duty of the teacher to train himself in teaching is next insisted on, and it is asked, "How many medical professors have given serious study to the science and method of education?"

In considering clinical experience under supervision it is observed that students have increased more quickly than hospital beds, and that tuberculosis, cancer, and syphilis are often sent to special hospitals, thus restricting the practice in the hospitals of the medical schools. Also, more beds are needed now owing to increased study requirements. Towards overcoming these difficulties more use may be made of hospitals hitherto unconnected with schools—ordinary voluntary and Poor Law hospitals; likewise there are the new clinics of local authorities, sanatoriums, dispensaries, infant welfare centres, and venereal disease clinics, school clinics, and so forth. Lastly, as in Ireland, fourth and fifth year students might have three months' stay in hospitals, half the time attached to the medical wards and half to the surgical.

## UNIVERSITY CLINICS (CLINICAL UNITS).

Sir George Newman, who attaches much importance to these clinics, gives an interesting historical survey, and enumerates the component parts of a university clinic as follows:

- (a) An adequate whole-time and part-time staff.
- (b) The control of wards (50 to 100 beds).
- (c) A proper
- (d) Ample
- (e) Adequate

He holds that the new recommendations of the General Medical Council express precisely the desired developments, so that "the entering student shall be better furnished for the medical course, and that the contributory sciences shall be integrated." The purpose of the university clinic is teaching and the advancement of learning. The question of whole-time staffing is considered, and various alternatives are discussed, the opinion being reached that in this country the head of the clinic would be permitted to undertake such degree of outside private practice as would not interfere with

<sup>1</sup> Recent Advances in Medical Education in England. A Memorandum addressed to the Minister of Health by Sir George Newman, K.C.B., M.D., Hon. D.C.L., F.R.C.P., Chief Medical Officer of the Ministry of Health and of the Board of Education. Crown Notice to the General Medical Council, London: H.M. Stationery Office, Imperial House, Kingsway, W.C.2, 1923. 1s. 3d. net. (The first notice was published last week at page 723.)

his official duties. As to the rest of the staff the objective would be

not only the "setting apart of one or more whole-time clinicians for educational work, but the best method of creating a team of clinicians who are also laboratory workers, in a unit, under the leadership of a professor who has control of beds, laboratories, and out-patient department, with adequate provision as regards time, equipment, and teaching ability, in order that the clinical education of the student may be directed along lines that will produce the best treatment for patients and the advance of knowledge."

The subject of university clinics is further discussed under the headings of study in the ward, teaching in out-patient department, laboratory work, and auxiliary equipment. Then the present position in this country is considered, and it is said that "the organization is not a new invention, but is the natural development of the English system of clinical teaching," which development may well be allowed to proceed naturally and gradually. Three years of it are held to have shown substantial improvement both in teaching and in treatment of patients; more time and supervision is devoted to students, more work is done by clerks and dressers, and there is less spoon-feeding. The methods and spirit of research are essential in the routine of the university clinic, which is a training school for its staff in the art of teaching. "Lastly," writes Sir George Newman, "the university clinic is integrating medicine," and education is no longer in watertight compartments. The dangers of an unsuitable director are recognized, but as they receive their appointment from the university that body has its remedy.

#### OBSTETRICS AND GYNAECOLOGY.

The fact that 60 per cent. of confinements are now attended by midwives increases the proportion of difficult cases left to the medical profession, and at the same time the midwife is bound to call in a doctor to every complicated labour. Yet a committee of the Royal Society of Medicine reported in 1919 that while "the systematic instruction given is, generally speaking, satisfactory, and is in the hands of obstetric physicians," unfortunately "the practical instruction leaves very much to be desired, and in some respects merits emphatic condemnation." The main defects were reported as want of beds and of ward teaching, but great improvement had followed the establishment of midwifery wards at certain hospitals, though the teaching was still insufficient. The committee recommended the establishment of obstetric "departments" in some of the larger teaching hospitals with existing maternity wards, and new "centres" in outlying districts of the metropolis, for instruction of medical students apart from pupil midwives, and for ante-natal, natal, and post-natal work. Though additional provision has been made it is still insufficient, and out of over 5,000 beds in the twelve London teaching hospitals there are only about 150 for midwifery and 300 for gynaecology. Poor Law institutions should be used to supplement these, and the claims of the medical student for teaching should come before all others. Sir Francis Champneys reported to the General Medical Council in 1920 that many women trained for the Central Midwives Board examination never practise as midwives, and in about twelve years the cases allotted to such women for training amounted to no fewer than 356,420; at present, indeed, only 22 per cent. of trained midwives actually practise as such. In the provinces increased provision of maternity homes has been made, but most of it is used for pupil midwives. General organization, however, is being improved at many medical schools, and the progress of ante-natal work advocated and illustrated by the late Dr. Ballantyne in Edinburgh has advanced the practice of preventive medicine.

Sir George Newman sketches a scheme of obstetric teaching, and in accord with the General Medical Council advises that each medical school should have available a complete obstetric department, in which senior as well as junior officers should teach, the courses of instruction including obstetrics, diseases of women, and pediatrics, with due integration of the earlier subjects of the medical curriculum with obstetrics. A syllabus of the course is outlined under lectures, demonstrations, clinical teaching, and maternity district work. The clinical teaching should include ante-natal clinic, labour wards, lying-in wards, infant welfare centres, gynaecological wards and operating theatre, out-patient department, and female venereal department. Midwifery should be taught at the bedside just as medicine and surgery are, and records kept of work done. In his report to the General Medical Council, Sir William Smyly, who inspected for the Council the final examinations in these subjects, advised that a clinical

examination should be required wherever possible, and the Council has recommended that "in midwifery, where a clinical examination is not held, the duly attested record of the work done by the candidate in clinical midwifery must be presented to the examiners for assessment in the final examination."

#### PREVENTIVE MEDICINE IN MEDICAL PRACTICE.

Sir William Osler wrote:

"When the thoughtful historian gets far enough away from the nineteenth century to see it as a whole, no feature will stand out with greater distinctness than the fulfilment of the prophecy of Descartes that we could be freed from an infinity of maladies, both of body and mind, if we had sufficient knowledge of their causes and of all the remedies with which Nature has provided us. Sanitation takes its place among the great modern revolutions—political, social, and intellectual. Great Britain deserves the credit of the first practical recognition of the maxim *salus populi suprema lex*."

The foundation knowledge required for preventive medicine is in three departments—the natural history of disease, the cause and circumstances of disease, and the effect of environment. Though in recent times the laboratory has played a great part, it is the general practitioner who laid the foundations—Harvey, Sydenham, Mead, Fothergill, Heberden, Huxham, Baker, Withering, Jenner, Lind, Thackeray, and Taylor of Penrith. In the work of all of them prevention and cure were associated, though engineers, analysts, and administrators are agents in its communal applications; even to-day "much of the actual investigation and differentiation is falling to the medical practitioner."

The application of the scientific method to the control of infections intimately concerns the practitioner, and includes (a) study of causes, and early diagnosis; (b) prompt application of prophylactic methods, such as serums and vaccines; (c) notification; (d) isolation and treatment; (e) disinfection when necessary; (f) detection and control of "contacts" and "carriers"; and (g) the adoption of special methods varying in different diseases.

The sphere of preventive medicine extends beyond infectious diseases. There also come within its scope abortion, miscarriage, stillbirths, much infant mortality, children's disorders, such as ophthalmia, rickets, dental decay, and malnutrition, and many diseases of skin, eye, ear, nose, and throat, and among adults much physical impairment due to causes in large measure preventable—rheumatism, dyspepsia, constipation, bronchitis, anaemia, and various others. In surgery, asepsis is a preventive measure, and prevention applies to various conditions both in children and adults, including industrial surgery.

For such reasons the General Medical Council recommends "that throughout the whole period of study the attention of the student should be directed by his teachers to the importance of the preventive aspects of medicine." It is to be a pervading influence. The kind of knowledge needed for the practice of preventive medicine includes personal hygiene of body and mind, a grasp of the etiology of disease, an appreciation of the place and purpose of hygienic environment, and a realization of the effects of social evolution.

"What has been the medical effect of industrial revolution or the introduction of steam? of elementary education and religious liberty? of the improvement of roads and transport? of the rise and fall of wages and the cost of living? of the importation of meat and corn? of the growth of the towns?"

Nothing can indicate better than these questions the breadth of outlook of the author of the Memorandum, and the answers he gives to some of them are stimulating. After consideration of ways and means for giving effect to the Medical Council's policy of permeation of the whole curriculum by the principle of prevention, the chapter ends with the following forecasts:

"As the National Health Insurance Service becomes established it will prove an effective instrument of preventive medicine, for, by its means, the patient will be brought into the doctor's hands at an earlier stage, and in due time the doctor will have the preventive attitude and method of instruction of medical students. Direct instruction of medical students in preventive medicine or lectures should not be overlooked as being overweighted with public health."

#### SPECIAL SUBJECTS ASSOCIATED WITH MEDICINE.

**Pediatrics.**—The General Medical Council has placed pediatrics foremost among special subjects, and the Memorandum urges that every medical school should have a

department of pediatrics, that a definite period of time—say, three months—following obstetrics should be allocated to child study, and that the subject should be included in the final examination. "Systematic pediatrics (as taught in America) and child welfare (as practised in England) should be associated together, for they are mutually complementary and interdependent."

**Psychology and Psycho-pathology.**—The requirements of the general practitioner in this branch of knowledge are a clear account of modern psychology, a concept of the unconscious mind, the worth of self-study of normal psychological phenomena, and of deductions from study of abnormal but not insane patients as bearing on therapeutic measures. He must be prepared for emergencies and for diagnosis of the chief forms of mental disease and defect, and for certifying under the several Acts. It is important that mental inefficiency and impairment be prevented, or be detected as early as possible with a view to effective treatment. All this needs training by a course of instruction and clinical work, first in a mental hospital and then in an out-patient clinic. The curriculum, it is suggested by Sir George Newman, should consist of five to ten lectures in normal psychology, preferably in the physiology course; half a dozen explanatory discourses in abnormal psychology, concurrently with clinical work in mental disease; ten or twelve systematic lectures on mental disease, also concurrently with clinical work and demonstrations at a mental hospital; and a series of demonstrations in the out-patient clinic for mental disorders at a general hospital. Medical schools are not yet sufficiently equipped for proper instruction, but advantage should be taken of the special schools for mentally defective children.

**Ophthalmology.**—Eye affections are so common from birth onwards that this is not properly a special subject. By stages the General Medical Council has come to require, in the new curriculum, instruction in diseases of the eye, refraction, and the use of the ophthalmoscope—requirements which have been in great measure forestalled at many medical schools, though uniformity of instruction and examination has been lacking. The licensing bodies are at present organizing courses.

**Veneral Disease.**—The 190 clinics now established for free treatment are available for the education of students. The subject is compulsory, and as an example of a course of instruction a scheme suggested by experience at the St. Thomas's Hospital clinic is set forth in the Memorandum. It includes bacteriology, pharmacology, demonstrations, lectures, and clinical work. The value of ante-natal treatment for both mother and child should be impressed on the student.

**Dental Education.**—Sir George Newman presents a lucid sketch of the facts and considerations which have gradually but inevitably led up to the new dental curriculum and the new *Dentists Register*, as well as to the penal prohibition of unregistered practice. The aim of the Council in the new scheme is to provide "a minimum curriculum without impairing the standard of efficiency." The revised curriculum is given in full in the Memorandum, and it is affirmed that "dentistry may now become, for the first time, an organized instrument and means of preventive medicine." The new *Register* includes 13,000 names.

#### PUBLIC HEALTH.

As long ago as 1863 the British Medical Association urged the General Medical Council to consider the qualifications required for holding office in what has now developed into the public health service of Britain. The Medical Act of 1885 conferred on the Council the power to register such qualifications, and recognition was given to certificates or diplomas which had already been granted by licensing bodies. Later there came the statutory requirement that for some offices such diplomas were to be essential, and so, under rules issued by the Council, the organization developed. The rules have now been revised and strengthened, and, so altered, take effect as from the beginning of 1924. They are based on the Council's agreement with the dictum of Dr. Bruce Low in his report of his inspection of the D.P.H. examinations throughout the United Kingdom, that "it is of national importance that weak or unsuitable candidates should, as far as possible, be kept out of the Public Health Service of the country." The scope of study includes maternity, infant, and child welfare,

tuberculosis, venereal disease, occupational and food-borne disease. The candidate is required to work with a medical officer of health for not less than six months, and "must go and see and learn the practice of the branch of medicine he has chosen to follow;" also he will not be allowed to obtain his diploma until a minimum of two years after his qualification in medicine, so that there shall be at least an opportunity for some development of maturity of thought and outlook, in whatever department of study and practice the interval be spent, whether in a laboratory, a hospital, a dispensary clinic, or sanatorium, assistantship in general practice, or other medical occupation. The new rules are quoted in full in the Memorandum, and it is pointed out "that Part I is analogous to the intermediate sciences in the medical curriculum, and Part II to the clinical art of applying these in practice."

#### CONCLUSION.

Sir Clifford Allbutt wrote in 1919: "It is revealed to us that Medicine has come to a new birth . . ."; it has changed "from a craft of tradition and sagacity to an applied science of analysis and law; from a descriptive code of surface phenomena to the discovery of deeper affinities; from a set of rules and axioms of quality to measurements of quantity." After the mediaeval centuries of darkness, Sir George Newman writes, "the new day dawned in 1543, when Vesalius published his *Fabrica* at Basel and Copernicus his famous book at Nuremberg on the revolution of the planets round the sun;" and the Memorandum goes on to give a rapid sketch, mentioning the introduction of the stethoscope and the beginnings of physiology, pathology, anaesthesia, bacteriology, protozoology, immunology, asepsis, internal secretion, and cardiology. "The representatives of medicine and science have thus come to the aid of the nations, to the succour of the human race." Within our own time we have seen the advance of public medicine, the organization of research, the growth of medical and surgical treatment, and the reform of medical education. The training of the physician affects the well-being of the State, but he is also the trusted confidant of his patient, and on this ground his education and his function must be individualistic. The inspiration of reform is the prevention of disease. "Curative medicine and remedial surgery must have immediate priority, but the ultimate goal is prevention." The future of medicine in England depends not merely on proper training to obtain a registered qualification, but "upon continued education after graduation." Four requirements are emphasized in the conclusion, and may be condensed thus:

(a) The necessity of integration in the medical course and avoidance of overburdening the student with details, so that he may "reflect and comprehend and grow." The teacher should be an *educationalist* and realize this.

(b) Clinical study must remain the sheet-anchor of education. Instruments and apparatus should be only supplementary to observation by the organs of sense; final judgment should depend on acumen and competence.

(c) The load of examinations should be lightened, notwithstanding the good purpose and competency of examiners; "the system remains a shackle upon medical education," and the student's course is standardized not by love of learning, but by the prescription of the examining body. In 1922 the General Medical Council resolved that "In the regulations for the several examinations it should be provided that examiners, in assessing marks, be empowered to take into account the duly attested work done by the candidate throughout his course of study in the subject of the examination."

(d) Post-graduate courses are necessary to keep the practitioner informed of new medical knowledge and its applications. In London a central scheme is necessary for the graduates of the twelve schools, and for medical men from the colonies and foreign countries. Other countries have much to learn from us and we have much to learn from them.

Financial assistance from the Treasury to medical education is justified, and the Memorandum contains evidence of its wise and economic use. Notwithstanding all that has been accomplished, the author of the Memorandum holds that the present reform movement in medicine is only at its beginning. No doubt he is right, and his own present contribution to the movement will, by informing the profession and the public of what is being done and what is being aimed at, give new and very valuable stimulus to the progress of which he makes himself the chronicler.

## SYPHILIMETRY.

Our Paris Correspondent referred a few weeks ago (p. 652) to a system of controlling the effects of anti-syphilitic treatment devised by Dr. Vernes and described by him in a series of communications to the Académie des Sciences. He has in Paris an Institut Prophylactique, where a large number of cases are dealt with, and, as our correspondent mentioned, a public appeal has been launched in France, with very influential support, to defray the cost of adding to the prophylactic institute a teaching establishment where medical practitioners can make themselves acquainted with the details of the method Vernes recommends. It should be said that the method does not command universal approval in France and has not been generally adopted by syphilologists and pathologists. Indeed, recently, a number of syphilologists issued a counter-manifesto criticizing the grounds upon which the appeal is being made. The method has been briefly mentioned in our columns,\* but it has not hitherto attracted much attention in this country, and an account of it may be of interest.

In the first place it is to be observed that the limitations of the Wassermann test are well known and are particularly felt when it is desired to know how far a given course of treatment has gone towards eradicating syphilis. Attempts to solve the problem have been made; for example, Weichardt, in his epiphannin test, and Ascoli in his meiostagmine test, made use of the alteration in surface tension of certain substances which occurred when mixed with syphilitic serums. Others, notably Sachs and Georgi, Meinicke, Kolmer, and Dreyer and Ward (Sigma test), have relied upon the flocculation which occurs when syphilitic serum is added to organic extracts in correct proportion.

In Vernes's test suitably diluted "péréthynol" (an alcoholic and ethylene dichloride extract of horse heart) is used, and the flocculation produced is measured. The péréthynol is so prepared that when mixed with distilled water under a given set of conditions a colloidal suspension is obtained of definite uniform opacity. This suspension is adjusted to give no flocculation with a normal serum and varying degrees of flocculation with a syphilitic one, the amount of flocculation being proportional to the intensity of the infection. In order to measure the degree of flocculation he originally added pig serum, which interferes with the flocculation of a péréthynol-syphilitic-serum mixture, and in doing so loses another property it possesses—namely, the power to dissolve sheep's red corpuscles. The measure of haemolysis is therefore inversely proportional to the original flocculation, so that no haemolysis indicates a strong reaction, and complete haemolysis no reaction between the tested serum, the péréthynol, and the pig's serum. More recently he has adopted the method of measuring the flocculation directly by an opacimeter, thus dispensing with the pig serum and the red cells. A reading is taken by comparing the amount of light cut off by the opacity of the fluid (female venereal serum and péréthynol) and that by the bedside just as medicine is in distilled water). The kept of work done. In his report

difference between the two is read off on a scale and referred to a table which gives the weight of precipitate in milligrams per cubic centimetre. This method promises a much more exact means of measuring flocculation than the naked eye or hand lens commonly employed in other flocculation tests. The instruments for measuring and delivering the various quantities of the reagents, and for their preparation, and, above all, the optical instrument for estimating the amount of flocculation, are models of ingenuity, but the cost of the installation of the apparatus for the performance of the test must militate against its adoption, except where very large numbers of tests are to be made.

Vernes claims that the direct measurement gives a far wider range than the indirect. The diagnosis does not depend on a single test but on the curve which is plotted out from the degrees of reaction discovered in a series of tests. Vernes claims that by his test the patient's progress can be measured accurately and cure determined eventually with complete certainty.

If, following arsenical treatment, the patient is going to relapse serologically the relapse occurs usually from the second to the fifth month, rarely during the sixth, and very rarely during the seventh. If there has been no reaction in serum on eight monthly tests following suspension of treatment and if it is negative also in the cerebro-spinal fluid the patient may be considered permanently cured. Vernes states that in a very large number of cases, extending over a long period, he has never seen an exception to this rule. Children conceived by parents who satisfy these conditions have never in his experience shown clinical or serological evidence of syphilis; moreover, a person who has fulfilled them may contract syphilis anew.

Dr. Vernes does not appear to employ any unusual remedy, but insists that it is the rhythm of the treatment rather than the amount which is of importance, though he does not make clear exactly what he means by rhythm—that is, how he decides on the amount and spacing of his doses of arsenobenzol. The treatment is controlled by the test, and when the serum has been brought to give no flocculation with péréthynol a test is carried out each month; if the reaction tends to return more treatment is indicated.

Though, as has been said, syphilimetry has attracted little attention in this country, a certain amount of work on it has been done in America, notably by Cornwall and Aronson. The former reports the results of comparative Wassermann and Vernes tests on 232 serums and 130 cerebro-spinal fluids. The tests on serums agreed in 68 per cent., the balance of 32 per cent. being in favour of the Wassermann in 25.5 per cent. and in favour of Vernes in 6.5 per cent. Of the 130 cerebro-spinal fluids the results agreed in 80 per cent.; of those disagreeing the balance was in favour of Vernes in 16 per cent. and of Wassermann in 4 per cent. More recently in France cases have been reported in which the Vernes test was positive in non-syphilitic cases and negative in florid secondary cases. At a meeting of the Société française de Dermatologie et de Syphiligraphie on November 9th, 1922, Leredde reported three cases of undoubted active syphilis in which the Vernes test was negative, and his evidence was supported by Ravaut, Gougerot, Flaudin, and Pinardo.

If syphilimetry is all that its author claims for it, it is certainly very attractive; but in view of the above, and until the test has been confirmed by a number of well qualified observers over a considerable period of time, it must be accepted with caution.

The need for caution is confirmed by the terms of the manifesto to which we have already referred; it was signed by a large number of leading syphilologists and was published in the Paris newspapers evidently as an appeal for further work.

\* See to be found in the *Atlas de* review of which appeared in the *Ann. Med. (Paris)*, 1921 (p. 857). The optical method has been described by Vernes in

The manifesto states that the signatories consider it their duty to call the attention of the public to certain points. The first is that the method of diagnosis called flocculation is not new, is not superior to other methods of sero-diagnosis of syphilis, and even appears in a number of cases less sensitive and trustworthy; secondly, it is pointed out that it is an established practice to follow the evolution of syphilis by the study of serological reactions and to judge the effects of treatment from them, but that it is neither possible nor safe to measure the degree of syphilitic infection numerically. The signatories also consider it imprudent to assert that syphilis has been cured because the flocculation test and other laboratory controls remain negative for eight months. Their general conclusion is that the prophylactic institute is applying neither a new method of diagnosis nor methods of treatment superior to those employed by other doctors.

### THE PSYCHOLOGY OF DREAMS.

THE substance of a series of lectures delivered by the late Dr. W. H. R. Rivers at Cambridge and elsewhere has been published in a volume entitled *Conflict and Dream*.<sup>1</sup> It is fortunate that the manuscript of these lectures was left in a form which made it possible for Professor G. Elliot Smith to prepare it for publication; otherwise the psychologist would have been deprived of a thoughtful contribution to one of the most obscure problems of mental life. The pleasure of reading this particularly clear and interesting book on dream psychology must inevitably be tinged with regret that the author did not live to continue investigations so full of promise.

Study of his own and other persons' dreams led Rivers to accept, though with important modifications, Freud's scheme of the processes by which the dream is produced. He makes this scheme the starting point of his discussion, and subjects Freud's theory to criticism from various points of view. The essential and most original feature of Freud's teaching is that dreams as a whole have a meaning, and that their psychological origin can be traced with certainty and precision by means of his psycho-analytical technique. Such a view is in striking contrast to that previously held by most psychologists—namely, that the dream is an anarchical and chaotic revival of memory images to which no meaning can be ascribed. Though some dreams are difficult to explain causally, the view that they are motivated by unconscious tendencies, as are the thoughts and actions of waking life, would appear to be reasonable, in spite of the seemingly meaningless character they present. The same forces which impel the individual into ceaseless mental and physical activity during the day may be assumed to seek expression, and to control the thought processes, during sleep. Dr. Rivers accepts this view without hesitation, but arrives at the meaning or latent content of the dream by a method which differs from that utilized by Freud in his interpretations. In an interesting chapter he criticizes the method of free association as an instrument for elucidating the meaning of the dream. He does not question the value of the psycho-analytic technique as a method of diagnostic value, but he doubts whether the thoughts reached by the process of free association have necessarily taken a part in determining the dream.

When Dr. Rivers began to analyse his dreams he discovered that as soon as he became awake he was already having, and had for some time been having, thoughts about a dream, the dream itself being still clearly in his mind. He regards this unwitting or partially unwitting

method of analysis as one especially likely to lead one to the real thoughts and emotions forming the latent content of the dream. By following this procedure he found that the dream images merged by insensible gradations into waking thoughts, and the solution of the dream came in a more or less spontaneous way. Dr. Rivers felt that the interpretations given by Freud were forced and arbitrary, and his own investigations led him to criticize Freud's dream formula as unduly simple and as an inadequate expression of the relation between the manifest and latent content. Basing his view on the personal study of dreams, a number of which are described in this volume, he suggested, as an alternative to the wish-fulfilment theory, the hypothesis that the dream is the solution or attempted solution of a conflict which finds expression in ways characteristic of different levels of early experience.

The essential difference between this hypothesis and Freud's is the stress laid on recent conflicts in the motivation of the dream. According to Dr. Rivers, while the structure of the dream is infantile and primitive, it is determined by adult interests; putting the matter in very simple language, it may be said that the opposing impulses and troubles of daily life continue to preoccupy the individual during sleep, though expressed in a disguised, grotesque, and fantastic form. On the other hand, though Freud recognizes that recent, superficial, and conscious wishes take their part in the dream, he considers that they do so only in so far as they are associated with a primitive, infantile, repressed tendency of which the individual is normally unconscious. From the standpoint of Freud the dream is to be regarded as the distorted expression of a primitive impulse seeking only its own ends; he holds that the process of dream-making involves no intellectual operations, has no constructive value, is non-creative, and reaches no conclusions. Rivers, on the other hand, regarded the dream processes as more allied to the thoughts and behaviour of waking life. He found that dream thoughts are primarily concerned with the external situations of daily life; the tendency to harmonize conflicting interests, to develop new and useful combinations of images, and to find solutions, he regarded as characteristic of the dream consciousness as it is of the waking. He describes a number of dreams in which he detected evidence of a constructive process, and suggested that the dream may be capable of solving or helping to solve practical problems which may be presented in the course of daily life, and, though in symbolic and fantastic form, may express conclusions better than those reached in daily life. He explained the superiority in this respect of the state of sleep to the waking life on the hypothesis that during sleep the conflict between opposing impulses is free and open. One impulse is not thwarted by another as when awake; both have equal play, so that the imagination can apply itself without restraint to finding a solution of the conflict.

This theory of the dream as the solution or attempted solution of a conflict he applied to the elucidation of the difficult problem of the affect in dreams. Briefly, the view taken is that the different degrees of painfulness of the affect depend on different degrees in which the dream forms a successful conclusion; in dreams accompanied by no appreciable affect a satisfactory solution of the conflict upon which they depend has been reached, but where the solution of the dream is completely unsuccessful there is an affect of a highly painful kind. Rivers was in agreement with Freud that the effect of transformation of the latent content is to diminish the affective aspect of the conflict, and that where there is considerable transformation there is little affect; but he did not accept the explanation of this transformation—or, as Freud prefers to call it, distortion—by reference to

<sup>1</sup> *Conflict and Dream*. By W. H. R. Rivers, M.D., D.Sc., LL.D., F.R.S. With a Preface by G. Elliot Smith, F.R.S. London: Hogarth Press, Trench, Trubner, and Co., Ltd. 1923. (Pp. xi+195. 12s. 6d. net.)

the agency of the censorship. He supposed that the relaxation of higher mental levels during sleep permits earlier levels of mental activity to function, and thus, though the dream is concerned with recent conflicts and external situations, its structure is primitive, regressive, and infantile.

Rivers in these lectures gave only brief consideration to the relation of dreams to pathological mental processes, myths, and the products of artistic activity. Here he touched on very big problems, and was only able to deal with them in a cursory manner. He believed that in mental disorder, as in dreams, the importance of early experience has been greatly exaggerated by Freud and his followers, and he ascribed considerable pathogenic significance to recent conflicts in the production of abnormal mental states. Except in a limited number of cases this view would scarcely seem to harmonize with the facts of clinical experience. If it were generally applicable the psycho-neuroses would be much more amenable to treatment than is actually the case, and it is doubtful whether any but the mildest cases are the outcome of superficial conflicts and external difficulties, though such factors, no doubt, have a certain influence in provoking more pronounced episodes of inadequacy in habitually neurotic persons.

In an interesting and important lecture on symbolism and dreams Rivers subjected Freud's theory of universal symbolism to criticism. Freud believes that the fundamental and perennial interests of mankind re-create afresh out of individual material stereotyped symbols, and that, while many of these symbols cannot be interpreted by the method of free association, their meaning can be supplied from a knowledge of myths, folk-lore, and primitive beliefs. The arguments advanced by Rivers against this view are based on a study of his own dreams, in which he shows that symbols have a variable interpretation, and on his ethnological researches. The latter led him to believe that no systems of symbolization are of universal distribution, and that the so-called innate symbolism is the result of a common tradition so prevalent that it influences every member of the community, and becomes, perhaps at an early stage of his life, part of the furniture of his mind. He was thus led to the conclusion that the tendency to symbolize certain thoughts by means of the same symbols, or by symbols having a close similarity to one another, is not instinctive but acquired; it is part of the "social heritage." His views on this subject have been expressed more fully elsewhere in various papers, and it is to be hoped that these also may be collected in a book.

#### COUNTRY LIFE AND COUNTRY DOCTORS.

MR. LLOYD GEORGE—who has the knack, if we may use the expression without offence, of putting into words thoughts which other people are beginning to formulate—enumerated in his address to young liberals at Manchester last week certain matters in which the English and Welsh, if not the Scots, were wasteful. One was waste of health and its attendant energy by bad housing, about which, in large towns at least, there is little room for doubt; another was waste of coal, and it is certainly wasteful to pollute the air by turning tons of combustible material into it, but this probably was not what he was thinking of. Another was the waste of brain power for lack of education, about which until he will define the meaning of education in this connexion there is room for two opinions; and the fourth was the wasteful misuse of land. He quoted Lord Ernle for the assertion that Belgium raised five times as much to the acre, and Germany twice as much, as Great Britain. Mr. Lloyd George, true to the political doctrine by which he has often preached before, believes that a change in the laws would be a remedy. But it is strange that the laws

Great Britain has been able to breed the best cattle, sheep, and pigs in the world, as is proved by the prices given by foreign buyers for pedigree animals. He went on to say that the population on the land is diminishing decade by decade, whereas in other countries—he mentioned Belgium, Denmark, France, Holland, and Germany—it is increasing. To consider whether the last clause is strictly accurate or not would take us too far, but there is no doubt that our rural population is decreasing, and we are glad that a leader of Liberal political opinion should have so quickly come in to endorse and reinforce the thesis Dr. Williams-Freeman so ably maintained from a particular point of view in the brilliant little essay published in the SUPPLEMENT on April 21st. The country doctor is friend and helper through all the countryside; he suffers with the rural community, and it suffers in its dearest interests and in its efficiency through the handicap under which he works. Mr. Lloyd George was the father of the Insurance Act, which worked something like a social revolution; it was impossible to foresee all its effects, but its most ardent advocates did not assume that its working would not disclose defects. We feel sure that Mr. Lloyd George at any rate did not. Will he not look into this matter of the plight of the country doctor, and use his great influence to see that justice is done to him and to the country people among whom and for whom he works? No great sum is needed, and the coffers of the Insurance Commission are perhaps fuller than some would have us believe.

#### THE OPHTHALMOLOGICAL SOCIETY'S CONGRESS.

THE annual congress of the Ophthalmological Society of the United Kingdom was held under the presidency of Mr. Maitland Ramsay, of Glasgow, on April 26th, 27th, and 28th. There was a large attendance of members and many interesting papers were read. The proceedings opened on Thursday, the 26th, at the Royal Society of Medicine. After the President's opening address, Mr. Treacher Collins and Sir William Lister each contributed a paper on that interesting and somewhat rare condition of angioid streaks in the fundus oculi. Then followed papers by Mr. Aspley Greaves and by Mr. Foster Moore upon their results of cataract extractions by Barraquer's method. Since Barraquer first published an account of his method its value as compared with older and more tried methods has been much discussed. In the afternoon a discussion on the disorders of the blood and their ophthalmological manifestations was opened by Sir Humphry Rolleston, Sir Frederick Andrewes, and Dr. W. C. Souther. At 5 o'clock there was a large gathering to hear Professor George E. de Schweinitz deliver the Bowman lecture on "Certain aspects of pituitary body disorders mainly exclusive of the usual central and peripheral field defects." Professor de Schweinitz held the large audience spellbound by his oratory. The lecture was illuminated by the results of much careful anatomical research of the pituitary body and its immediate anatomical relations, and contained many interesting suggestions as to the various probable and possible ways by which the optic nerve fibre might be involved by irregularities of the anatomical, physiological, and pathological conditions of the gland. This year's Bowman lecture will take a very high place in the records of this famous institution. The members dined together in the evening at the Langham Hotel. On Friday morning a discussion upon the diagnostic significance of proptosis was held. It was opened by Mr. Wilfred Trotter, Mr. Herbert Fisher, and Dr. Angus MacGillivray. Many members took part in the later stages, and the chief divergence of opinion appeared to be with regard to the treatment of those cases of proptosis which were due to arterio-venous communications in the cavernous sinuses. Papers by Mr. Holmes Spicer on "Secondary corneal opacities"—a subject particularly his own—and by Mr. Williamson-Noble on "Macular changes in thrombosis of the central retinal vein" followed. In the afternoon a clinical meeting was held at the London Hospital, where cases of interest were shown. In the evening a long list of papers and demonstrations had been arranged. They were of

interest and covered every line of thought and research in ophthalmology. On Saturday morning, after the business meeting had been held, the proceedings opened with a paper by Dr. Angus MacGillivray on "Enucleation of the eyeball under local anaesthesia." This paper produced much discussion and reminiscence from the members of the society. Mr. Leslie Buchanan followed with a paper on a new subjective visual phenomenon connected with neuralgia. Papers by Mr. Percival Hay on the working distance of patients with moderate and high myopia after correction; by Mr. Humphrey-Neame, on the results of further investigations on the passage of arsenic into the aqueous humour after intravenous injections of novarsenobenzol in rabbits; by Mr. Inglis Pollock on a case of pseudo-glioma; by Mr. Lindsay Rea, on ocular syphilis, with special reference to the treatment of interstitial keratitis; and by Mr. Alexander, on a theorem generalizing the optical problems of ophthalmoscopy and skiascopy, followed. The proceedings then terminated.

#### ACUTE SYMPTOMS AFTER GASTRO-ENTEROSTOMY.

SEVERE acute symptoms after gastro-enterostomy are usually explained by mechanical obstruction of the jejunum distal to the stoma. But that similar severe toxic symptoms may follow gastro-enterostomy without such obstruction is shown by three cases investigated by Haden and Orr,<sup>1</sup> who argue that an intoxication of the same nature as that elucidated by G. H. Whipple in intestinal obstruction may occur when impediment to the outflow of the contents of the blind duodenum allows toxic substances to be formed in a part of the intestine where absorption is rapid and complete. The symptoms and the changes in the blood and urine observed—namely, very high non-protein nitrogen and a well marked increase in the nitrogen excretion by the kidneys—were identical with those in intestinal obstruction. Renal insufficiency appeared to be ruled out, and the increase of the non-protein nitrogen in the blood and of the urinary nitrogen was ascribed to breaking down of the body protein by the toxin. One case showed well marked alkalosis and the other two, in which this investigation was not undertaken until the acute stage of the intoxication had passed, presented a high normal level. In the two cases in which the urinary chlorides were examined there was a very striking suppression of chlorides in the urine, the plasma, and the blood as a whole, which resembled that observed in pneumonia and ascribed by Whipple to the influence of a protease intoxication. This metabolic change was obviously closely related to the alkalosis, and might be due to fixation or utilization of the chlorides in the process of protein destruction, the sodium ion being thus free to combine with  $\text{CO}_2$  and to circulate as sodium bicarbonate with the production of alkalosis. It is possible that the utilization of chlorides in the process of protein destruction is protective, and that the administration of a sufficient amount of chlorides to keep the blood chlorides at the normal level may be effective in combating the intoxication. The authors have started an experimental investigation on dogs to determine the part played by the chlorides in these intoxications, and their results as bearing on practice may be anticipated with interest.

#### ESTIMATION OF SUGAR IN BLOOD.

THE memorandum of the Medical Research Council published on April 21st (p. 695) announcing that insulin was available for purchase stated that the manufacturers will be directed during the present period of restricted production to supply insulin only to those hospitals and to those registered medical practitioners who have proper facilities at their command for making accurate blood-sugar determinations. Consequently each hospital and practitioner supplied will be required to undertake, among other things, to make a careful correlation of the diet, of the blood-sugar changes, and of the

insulin dosage in each case. In this connexion we would call attention to a paper in the current number of the *Biochemical Journal* by Dr. E. G. B. Calvert, who describes a method of estimating the amount of sugar in blood which he has found rapid and reliable. He claims that the number of manipulations has been reduced to a minimum, and that the method is, therefore, particularly valuable in routine clinical work. It is founded upon the methods of Polin and Wu and Mackenzie Wallis and Gallagher. The amount of blood required can be obtained from a single prick of the finger and is greater than can conveniently be obtained by the blotting paper hitherto in general use. The blood is collected in a small platinum capsule of special design, the weight of which is known and remains constant. The capsule with the contained blood is weighed on a torsion balance, and capsule and blood are at once dropped into a short wide test tube containing distilled water, with which it can be completely mixed by a few turns of the test tube. As in other methods, the power of glucose to reduce an alkaline solution of copper is utilized. By the addition of phosphomolybdic acid to the cuprous oxide so produced a clear deep-blue solution is obtained, any unreduced copper being at the same time decolorized. The depth of colour is a measure of the amount of reduction, and consequently of the percentage of sugar present. This estimation has hitherto been made by comparison in a colorimeter with the depth of colour similarly produced from a solution of glucose of known strength. Dr. Calvert has replaced the standard solution by glass discs of the same shade and colour as the solution. A curve of correction for copper reduction is provided, and by its use an appreciable if not considerable error in the estimation of sugar is eliminated. It is claimed that the accuracy of the method is high, as the fullest use is made of the blood available, and that the method is so simple that estimations for several blood curves can be made concurrently.<sup>1</sup>

#### A JOURNAL OF HELMINTHOLOGY.

WE have received the first number of the *Journal of Helminthology*, which is being edited by Professor R. T. Leiper, and published from the Helminthology Department of the London School of Tropical Medicine. The subscription price for the annual volume containing five parts is 25s. The journal will appear bi-monthly and is primarily intended to provide for the prompt appearance of original papers and other communications written by the staff and associated workers of the various sections of the Department of Helminthology. The first number, which bears the date March, 1923, contains about forty-eight pages. Dr. A. J. Hesse writes on the development of *Bunostomum trigonocephalum*, a common nematode parasite of sheep; it is a close ally of the ankylostome, but Dr. Hesse shows that it is not capable of invading the host through the skin. Dr. G. M. Ververs contributes two articles. The first deals with the lung flukes (*Paragonimus*); a study of the cuticular spines and the size and shape of the eggs leads him to agree with the conclusions of Ward and Hirsch, that there are several species of this genus hitherto regarded as variants of *P. westermanii*. A series of figures shows that there are many variations in the internal organs, so that no specific characters can be based upon them. On the other hand, the cuticular spines are remarkably constant in the various species. It would appear probable that more than one species occurs in man. Dr. Ververs's second contribution deals with a number of new parasitic worms found in British Guiana during the visit of the Filariasis Commission in 1920. A study of considerable interest to those engaged in fur breeding in this country forms the basis of a paper by Dr. Goodey and Mr. T. W. M. Cameron, M.R.C.V.S., who have investigated the structure and life history of *Ascaris columnaris*, a common parasite of the skunk. This parasite has grown to be so extraordinarily prevalent on the

<sup>1</sup> Haden, R. L., and Orr, T. G.: *Bull. Johns Hopkins Hosp.*, Baltimore, 1923, xxxiv, 28-30.

<sup>1</sup> Information as to the cost of the apparatus can be obtained from A. Gallenkamp and Co., 19, Sun Street, Finsbury Square, E.C.; the coloured glass discs are supplied by Messrs. Baird and Tatlock, Cross Street, Hutton Garden, E.C.

ranches for skunk rearing started in this country just prior to the outbreak of the war as to have become a serious economic factor. The presence of the parasite appears to give rise to serious deterioration in the fur and produces fatal results when present in numbers. We congratulate the editor on having broken with the fashion of illustrating scientific papers by photographs and on presenting his readers with good line drawings, which are clearer and more informing.

#### EFFECTIVE RATES OF INCOME TAX.

A WHITE PAPER just issued by H.M. Stationery Office consists of tables which should be of interest to income tax payers. They show in the case of (a) single persons, (b) married couples without children, and (c) married couples entitled to the allowance for three children, the amount of income tax (including super-tax where the total income exceeds £2,000) payable on certain incomes, and the effective rates charged in the £, for the years 1922-23 and 1923-24. The proposed reduction in the standard rate of income tax (from 5s. to 4s. 6d. in the £) for the later period automatically involves a reduction from 2s. 6d. to 2s. 3d. in the £ in the rate of income tax chargeable on the first £225 of an individual's taxable income—that is, the actual income less the allowance in respect of earned income and less the personal allowances and deductions. The following figures show the amounts payable by married couples entitled to the allowance for three children on "earned" incomes ranging from £500 to £3,000, and the effective rate of tax (on incomes up to £250 there is no charge):

Actual Total Income.	Charge for 1922-23.		Proposed Charge for 1923-24.	
	Amount.	Effective Rate.	Amount.	Effective Rate.
£ 500	£ s. d. 16 17 6	s. d. 0 8	£ s. d. 15 3 9	s. d. 0 7½
1,000	118 2 6	2 4½	106 6 3	2 1½
2,000	343 2 6	3 5	208 16 3	3 1
2,500	505 12 6	4 0½	453 16 3	3 8
3,000	680 12 6	4 6½	621 6 3	4 1½

In the case of incomes exceeding £2,000 the above figures include super-tax as well as income tax.

#### M.O.H., CAPE TOWN.

THE South African mail this week brings two announcements regarding the Health Department of Cape Town. The *Cape Argus* of March 17th publishes an article on the forthcoming retirement, at his own request for reasons of health, of Dr. Alfred Jasper Anderson from the post of medical officer of health. Dr. Jasper Anderson arrived in Cape Town on October 1st, 1901, to take up the duties of first medical officer of health of the Cape Town Council; during the previous ten years he had been medical officer of health for Blackpool. With the unification of the Peninsula municipalities in 1913 he was appointed medical officer of health for the larger Cape Town area. The following summary of figures pays an eloquent tribute to his work in South Africa. In 1901 the European death rate was 17.1 per 1,000, and the coloured death rate 37.6. In 1915 the rates were 15.6 and 23.5. The infantile death rate among Europeans has declined during his tenure of office from 136 per 1,000 to 98.3. Although retiring from his association with the municipality, Dr. Anderson will continue to live in Cape Town. The *Cape Times* of March 28th reports a deputation from the Western Province Branch of the British Medical Association to the Cape Town City Council, in regard to the proposed division of the work of the Health Department into two sections. The deputation was introduced by Dr. C. M. Murray. Dr. Darley Hartley explained that in the Branch's opinion separation of the duties hitherto under the medical officer of health into two branches, curative and preventive,

would be detrimental to the public health. The Branch took no exception to this division so far as executive functions were concerned, but felt strongly that the ultimate administrative control should be with the medical officer of health, for the keynote of public health was unity of direction. The resolution he quoted from was adopted unanimously by a meeting of sixty-one members of the Western Province Branch. Dr. Moffat, who followed, spoke of the importance of maintaining one administrative head of all the health departments. The Mayor, in reply, pointed out that the Council last December decided to combine the office of medical officer of health with that of superintendent of the Infectious Disease Hospital; if that decision was to be reversed a unanimous rescinding resolution would be necessary. Dr. Abdurahman, Chairman of the Health Committee, argued against the views put forward by the deputation. The Mayor informed the members of the deputation that their views would be considered by the Council, and the interview closed. Subsequently Dr. T. S. Higgins, who for the past ten years has been medical officer of health for the borough of St. Pancras, London, was appointed to the post of M.O.H. Cape Town.

#### INFANT WELFARE CONFERENCE.

THE National Association for the Prevention of Infant Mortality and the National Baby Week Council are jointly organizing a conference on infant welfare to be held at Carnegie House, Piccadilly, on Monday, Tuesday, and Wednesday, July 2nd, 3rd, and 4th, under the presidency of the Right Hon. Neville Chamberlain, M.P., Minister of Health. The conference will coincide with the National Baby Week celebrations organized by the same bodies. Business will begin at 10.30 a.m. on July 2nd with the President's address, after which a discussion on "The causal factors of infant mortality up to 1 year of age (ante-natal, intra-natal, and post-natal) and their prevention" will be opened by Drs. Eardley Holland, J. S. Fairbairn, Eric Pritchard, and R. C. Jewesbury. In the afternoon the subject of maternity homes and their relation to maternal mortality from childbirth will be introduced by Dr. W. Allen Daley. On the morning of July 3rd Drs. W. G. Willoughby and Mabel Brodie will open a discussion on the scope, staffing, and administration of maternity and child welfare centres; in the afternoon the question, "Is it advisable in urban areas to combine the functions of the health visitor with those of other officers of local authorities?" will be debated; openers, Drs. E. W. Hope and F. Wynne. The morning of July 4th will be given up to a discussion, opened by Dr. Rhoda Adamson, on the maternity resolution passed by the Washington Convention, 1919, and the afternoon to housing in relation to infant welfare. During the conference visits will be made to a number of maternity and child welfare institutions of various kinds in London. Copies of the programme and information regarding fees may be obtained from the honorary secretary, Miss J. Halford (Carnegie House, 117, Piccadilly, W.1). The two organizations arranging the conference are sections of the National League for Health, Maternity and Child Welfare, of which the chairman is Dr. G. F. Still. The League acts as a co-ordinating body and a central clearing house for information. It has a lending and reference library, and is the publishing department for most of its sections. The work of five societies is thus carried out in one office with an interchangeable staff.

#### INTERNATIONAL CONGRESS OF THE HISTORY OF MEDICINE, 1925

At a meeting of the permanent committee of the International Society of the History of Medicine held at Antwerp on April 11th it was decided to hold the Fourth International Congress of the History of Medicine at Geneva, Switzerland, during the third week of July, 1925. The following officers were elected: *President*: Dr. Charles Greene, Cambridge. *Secretary-General*: Dr. A. de Peyer, Geneva. *Général Dufour*, 22. *President of Honour*: Sir Denis

Power, London. *Vice-Presidents of Honour*: Dr. Edward B. Krumbhaar, Philadelphia, U.S.A.; Dr. Tricot-Royer, Antwerp; Dr. J. G. de Liut, Gorinchem, Holland; Dr. Charles Singer, London; and the President of the Medical Society of Geneva for the year 1925.

#### INDUSTRIAL FATIGUE BOARD.

THE third annual report of the Industrial Fatigue Research Board, dealing with the year 1922, has been published (H.M. Stationery Office, 2s. net). The duty of the Board is to suggest problems for investigation, and to advise upon or carry out schemes of research referred to it by the Medical Research Council; to promote better knowledge of the relations of hours of labour and of other conditions of employment, including methods of work, to functions of the human body, having regard both to the preservation of health among workers and to industrial efficiency. The Board was instructed to seek the co-operation of industries in the fullest practical application of the results of this research work to the needs of industry. The report gives an account of the work of the Board and its several committees during the year. The inquiries fall under three general headings—general investigations, inquiries into industrial problems, and researches in various selected subjects. The bulk of the volume is made up of a series of individual reports, including two by Dr. H. M. Vernon, one on atmospheric conditions and efficiency, and the other on future investigations in the pottery industry.

### Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

#### *Dangerous Drugs (Amendment) Bill.*

THE Earl of Onslow, on April 25th, moved the second reading of the Dangerous Drugs and Poisons (Amendment) Bill in the House of Lords. He explained very briefly the provision, pointing out that people who committed purely technical offences were insured against the risk of the heavy penalties, because it was provided that no proceedings for an indictable offence should be instituted without the consent of the Attorney-General or the Director of Public Prosecutions. There was no discussion, and the bill was committed to a committee of the whole House.

#### *Colonial Medical Services.*

Dr. F. E. Fremantle asked, on April 25th, whether there is at the present time any difficulty in securing suitable candidates for the vacancies in the Colonial Medical Services, more especially those in the West Indies; what steps, if any, the Under Secretary for the Colonies had taken and proposed to take to secure action in the direction recommended by the report of his predecessor in respect of the medical services in the West Indies; whether, pending amelioration of conditions of service along the lines recommended in the report the Colonial Office proposed to continue recruiting for these services in this country; and, if so, what steps were being taken to advise intending candidates of the difficulties with which they would have to contend if they took up these appointments? The Under Secretary for the Colonies (Mr. Ormsby-Gore) said that there was no serious difficulty in securing suitable candidates for vacancies in the Colonial Medical Services, except as regarded appointments in West Africa and a few other posts for which it was possible to offer only small salaries. Effect had already been given to many of the recommendations regarding the medical services in the West Indies made by the President of the Board of Education when he was Under Secretary for the Colonies, but financial exigencies had prevented the realization of some of his proposals. There was no ground for thinking that the conditions of service in the great majority of the Colonial Medical Services were not satisfactory. Recruitment for these services was being continued in this country, but had been discontinued in the case of a few posts at low salaries in some of the poorer colonies. As full information as possible with regard to the terms and conditions of service was given to all intending candidates.

In reply to a further question by Dr. F. E. Fremantle, Mr. Ormsby-Gore said that the incidence of disease and the rates of mortality in some of the West Indian Colonies were capable of considerable reduction with great economic advantage. The Colonial Governments had given much attention lately to medical and sanitary matters; several had appointed committees of inquiry, and several had lately reorganized their public health services. In this work the Colonies were hampered by commercial depression and by the indifference of sections of the public which did not yet fully realize the profound importance of the community with the public to progress.

Dr. Fremantle asked, on April 30th, whether the Colonial Secretary had under consideration any proposals for ameliorating

the conditions of medical service in the Windward Islands; and whether he was aware that the conditions had been the subject of memorials from the Grenada Medical Service since 1919. Mr. Ormsby-Gore said that the decision would be reached at an early date, but he was sorry to say that the financial position of the Windward Islands was such as to restrict the possibilities of improvement in the conditions of the medical service.

Dr. Fremantle asked which colonies, and how many individual medical appointments, were affected by the discontinuance of recruitment in this country in the case of certain medical posts at low salaries; how these appointments were now filled by the several colonies; and what were the medical qualifications and nationality of the successful candidates for such posts. Mr. Ormsby-Gore said the question whether a medical appointment should be filled from this country was frequently decided only when a vacancy occurred, and that accordingly it was not possible to state definitely how many individual appointments were affected, but the number was probably between a dozen and a score. The appointments concerned were some of those in the Windward, Leeward, Bahamas, Turks, Caicos, and Cayman Islands. Most of them were filled by local West Indian candidates of British nationality possessing qualifications obtained in the United Kingdom or Canada. It appeared that there were only two medical men in the islands in question whose qualifications were foreign. Dr. Fremantle inquired whether the reason these posts were filled by persons holding American degrees was that the conditions of service were not such as to attract those with British qualifications. Mr. Ormsby-Gore replied that he believed those two doctors with American degrees were British West Indians.

Dr. Fremantle asked whether the Colonial Secretary was still, in the words of the Wood Report, always hampered in recruitment for colonial medical appointments carrying rights of private practice by the absence of sufficient data as to the value of such practice; if so, what steps had been taken by his department to give effect to the suggestion for removing this defect.

Mr. Ormsby-Gore said the value of a private practice must vary in accordance with individual capacity, and such information as the collector of the value of the appointment. The passage of this point was referred to the colonial governments concerned for their observations and no specific reply had yet been received. No difficulty had been encountered in the case of any appointment to these colonies since the date of the report. He believed that all that was done was to tell candidates in round figures what the private practice brought in to the previous occupant of the post.

#### *Pensions and Pensioners.*

The Pensions Minister stated, on April 26th, that the total number of awards declared to be final during the twelve months ended March 31st was approximately 246,000. In about 123,000 of the cases in which the final award was at the rate of less than 20 per cent. the men were previously in receipt of a conditional pension. He was unable to say in what proportion of these cases the disability was permanent, but only in a minority of not more than one-third of the whole number was the disability certified to be of indeterminate duration, and in most it was a minor injury in a final or stationary condition. The number of final awards in four-year cases in the year ended December 31st, 1922, was 54,600. The number of these cases which were at the rate of 20 per cent. or upwards and under 20 per cent. respectively was not at the outset especially recorded, but for the period for which a record was kept recommendations in favour of permanent pension were in the proportion of six to four recommendations for award of less than 20 per cent. The proportion of the former class showed a steady increase. A great proportion of the permanent pensions which were made "statutory final" were four-year cases. The average duration of final weekly allowances was about 80 weeks. The total number of men under home treatment with allowances is 7,215, and the total number of pensions and final weekly allowances is 707,000.

The Pensions Minister has said, in reply to a question, that in support of a claim made long after a man's discharge, that a disability from which he was suffering was connected with his service, the best evidence was evidence, whether medical or other, sufficient to establish the existence of the disability since discharge. But while this had always been pointed out by the Ministry in its instructions as an ordinary (though not by any means absolute) requirement, it had been clearly laid down that there were cases of latent disease which might not manifest themselves until very long after discharge, but might nevertheless be reasonably held to have been present before that date. The list of diseases of that class was drawn up on the advice of the highest independent medical authorities with the object of indicating that in the case of these diseases specially long periods after discharge could be allowed for the first known manifestation of the disease in order to establish continuous history. The following is a list of the diseases: Pulmonary tuberculosis, twelve months; general paralysis of the insane, eighteen months; subacute infective endocarditis, two years; diabetes, six months; aneurysm, one year; chronic granular kidney occurring in a man under 45 years of age, two years.

Major Tryon has stated also that reduction in the accommodation of the Ministry's hospitals would naturally follow on the decrease in the demand for in-patient treatment for pensioners. A considerable number of out-patient clinics had been established at convenient centres, and were administered by the Ministry, by civil hospitals, or by the British Red Cross Society on an agreed basis.

**Board of Control.**—Mr. Neville Chamberlain informed Mr. Ammon, on April 25th, that the total gross cost of the Board of Control for the financial year 1922-23 was approximately £470,236, less appropriations-in-aid (fees for licences, etc.) £7,756. The gross cost included grants-in-aid to local authorities and voluntary institutions £408,791, cost of State institutions for mental defectives £26,795, salaries and expenses, etc., of head office staff, £34,650.

**Deaths from Small-pox.**—In reply to Mr. Scrymgeour, on April 18th, Mr. Chamberlain said that 24 of the 27 deaths from small-pox in England and Wales last year occurred in the outbreak of virulent small-pox in London and the neighbourhood, and that in this outbreak the fatality rate was 23.7 per cent. in the case of vaccinated persons, and 60 per cent. in the case of unvaccinated persons. The age of the youngest vaccinated person who died from small-pox was 43. Seventy-two cases, of which 23 proved fatal, were nursed at the Metropolitan Asylums Board Hospital at Dartford between July 1st and December 1st, 1922.

**Accidents at Woolwich Arsenal.**—In answer to Sir Kingsley Wood, on April 23rd, who raised a question on the closing of the hospital at Woolwich Arsenal, Lieut.-Colonel Guinness said that an officer of the R.A.M.C. was always available by day and by night, and adequate facilities existed for the treatment of cases of injury pending their removal to hospital. Injured employees requiring in-patient treatment would in future be taken to the Royal Herbert Hospital, about a quarter of a mile distant. Apart from the Arsenal ambulance, always available in working hours, arrangements had been made with the Metropolitan Asylums Board for the immediate supply by day or night of fast motor vehicles. These would be drawn in the first instance from the Brook Ambulance Station close to the Royal Herbert Hospital. In the event of a very serious accident additional ambulances could at once be called up from neighbouring stations. The London County Council ambulances were also available. In his opinion the arrangements which had been made were satisfactory.

**Illness from Vaccination.**—Mr. Robert Young asked, on April 23rd, whether, seeing that the operation of vaccination was in many cases enforced, the Minister of Health would see that where untoward results ensued compensation for loss of health and employment wages would be paid, seeing that vaccination was *prima facie* in the interests of the community. Mr. Chamberlain said that the Vaccination Acts did not provide for the compulsory vaccination of adults, and he was advised that there was no statutory authority for the payment of compensation out of the rates in the circumstances referred to.

**Heart Cases and Dentures.**—Major Tryon, on April 19th, informed Mr. Becker where there was no dental disease due to war service but the extraction of teeth was recommended by the Pensions Department as a necessary part of treatment for an accepted disability, it was the practice to supply artificial dentures when necessary in the interests of a pensioner's health. In regard to a statement by Mr. Becker that a man undergoing treatment provided at the National Hospital for Diseases of the Heart, had had his teeth removed as part of the treatment, and the Ministry had refused to supply him with false teeth, Major Tryon said he understood that the need for artificial dentures had not been established in this case, but he was making further inquiries. Mr. Becker asked whether the Minister was aware that a large number of ex-service men had their teeth removed to assist heart treatment and had not had the money to buy dentures. Was the hospital supposed to supply these teeth, though getting only a capitation of 3s. per head? Major Tryon thought he had dealt with the point.

**Mentally Defective Children.**—Lord E. Percy informed Mr. C. Wilson, on April 19th, that the latest statistical information as to school accommodation for mentally defective children was contained in Appendix F of the report of the Chief Medical Officer to the Board of Education for 1920. In 293 areas for which data had been tabulated there were approximately 28,000 children reported as mentally defective in the category of "feeble-minded." This total included children under the local combined authority. The total accommodation provided in certified special schools for educable mentally defective children was over 16,000. As to the number that still required to be specially examined by school medical officers, Lord E. Percy said that his only information was from the medical officers themselves.

**Choice of Disinfectants.**—Mr. Chamberlain informed Mr. Becker, on April 18th, that he had no evidence to show that disinfectants totally devoid of bactericidal action were sold to the public. But he was aware that, judged by certain tests, disinfectants sold might differ considerably in their bactericidal power. As at present advised, he was not prepared to adopt the suggestion that a test should be required. Advice as to the choice of disinfectants for particular purposes could generally be obtained from the health officers of local authorities.

**Fee for**—Sir J. Remnant asked, on April 18th, whether the Minister of Health had been drawn to the representations of the Society of Medical Officers of Health, the British Medical Association and others relative to the inadequate charges authorized by the Ministry for the bacteriological examinations of the various grades of milk under statutory rules and orders, necessitating as it did the services of a skilled bacteriologist and the provision of the necessary material. Mr. Chamberlain said he had received the representations. He was advised that the work was of a routine character and that the cost per sample should not exceed the amount which had been suggested where

arrangements were made at the laboratory for dealing with the considerable volume of samples which might be expected to result from the scheme of milk grading.

**Nurses' Registration.**—In reply to a question as to the alleged growing resentment amongst registered nurses on the ground that the authority of the General Nursing Council for England and Wales had been usurped by medical men the Minister of Health said there was no evidence of any such feeling in the nursing profession, and the marked increase in the number of recent applications for admission to the Register seemed to him to negative the suggestion. The nurse members form two-thirds of the council, and it was within their power to control the selection of the committee. He understood that the chairman of three out of six standing committees were doctors, but he had no information on the other points, and was not prepared to make representations on matters wholly within the discretion of the council. In reply to another question Mr. Chamberlain said that an examination syllabus (Schedule 2) for the general part of the Register would be approved subject to two small modifications accepted by the council. The syllabus would form part of the rules and sufficiently indicated the subjects in which the candidate was required to be trained. The council had decided to make the syllabus of training advisory only as was allowed under Section 3 of the Act.

**Education Department Medical Service.**—On inquiry by Sir Joseph Leigh on April 20th Lord Eustace Percy stated that the promised co-operation between the Education Department and the Ministry of Health is now effective. The number of medical officers engaged exclusively at the Board of Education is seven.

**Health and Unemployment Insurance.**—Major Boyd-Carpenter, on April 17th, stated the total cost of administration of National Health and Unemployment Insurance per person relatively as follows: National Health Insurance, 6s. 8d.; Unemployment Insurance, 7s. 1d.

**Patent Medicine Stamp Duty.**—Major Entwistle asked, on April 17th, whether according to the constitution placed by the Customs and Excise Department upon the provisions of the Patent Medicine Stamp Duty Act, 1812, makers of chemical preparation sold under a fancy name, by not claiming proprietary rights, were able to avoid the incidence of the *ad valorem* Patent Medicine Stamp Duty. Major Boyd-Carpenter replied that the question whether any particular medicine was liable to stamp duty depended upon a number of considerations. If particulars of the case in mind were furnished to him he would have the matter looked into.

#### Answers in Brief.

The Minister of Health has stated that the Village Settlement Scheme for tuberculous ex-service men recommended by the Barlow Report of 1918 was under consideration, and would be discussed with representatives of the British Legion at an early date. The Hospitals Commission has distributed £421,023 of the Parliamentary grant of £500,000 in aid of the voluntary hospitals. The Commission has not yet made any recommendations as to the necessity for any future grant, or for the continuance of some central body to act as a link between the local voluntary hospital committees.

The general question of the salaries of health visitors is receiving the consideration of the Minister of Health. The Minister of Health has stated that the results of treatment and research in the leper asylums in India were being carefully studied in his department and would be discussed at the forthcoming international conference on leprosy at Strasbourg, at which this country would be represented by a medical officer of the Ministry.

The Parliamentary Under Secretary, Home Office, has stated, in reply to a question, that a bill to consolidate and amend the law relating to coroners is in preparation. He was unable to say when it would be introduced.

In reply to a question with regard to the arrangements for persons under remand in prison for mental observation and report, the Parliamentary Under Secretary, Home Office, said such persons were usually put into the prison hospital, but if the accommodation did not allow they were placed in cells provided for this purpose, and were supervised by the hospital officers. These cells were gated, and it was found by experience that they were the most suitable. They were located in special parts of the prison where few persons passed. The extension of the Birmingham scheme (as regards segregation and observation) to other prisons would involve structural alterations and the expenditure of large sums of money.

The number of ex-service men who have received a Government grant to enable them to finish their education at universities or colleges of similar standing in Great Britain is approximately 19,850, of whom up to the present about 10,110 have obtained a degree or diploma.

The number of persons in England and Wales in receipt of Poor Law relief on March 31st, 1923 (including lunatics in asylums) was approximately 1,439,000.

Four prosecutions have so far been instituted under the Debtors' Act, 1921.

The Minister of Health will at an early date discuss with the British Legion the question of village settlements for tuberculous ex-service men.

So far as the Colonial Office is aware no general opinion has been established in Iraq. In 1923 an attempt was made to control the opium traffic by local monopolies, but this had appeared to need regulation, and there is no reason to suppose that the High Commissioner is to furnish a report.

## X RAYS IN DIAGNOSIS.

## THE SILVANUS THOMPSON MEMORIAL LECTURE.

THE sixth annual Silvanus Thompson memorial lecture was delivered by Mr. C. THURSTAN HOLLAND, D.L., Ch.M., honorary consulting radiologist to the Liverpool Royal Infirmary, on Tuesday, May 1st.

After a reference to his predecessors—Rutherford, Bragg, Hill, Bayliss, and Lodge—he paid a worthy tribute to the memory of Silvanus Thompson, his work, and his position amongst physicists.

Mr. Holland took as the subject of his lecture, "The influence of  $x$  rays on diagnosis." Speaking of the Röntgen Society—the oldest of all the  $x$ -ray societies in the world—the lecturer said it had never been possible to draw a hard and fast line between the purely medical and the purely scientific, and that the society existed, to some extent, in order to bring together all interested in the study of  $x$  rays so that mutual benefit might result. The co-operation of physicists, manufacturers, and radiologists was practically an essential of advance.

*Early Days.*

He related how in December, 1895, Röntgen first published the details of his discovery, in a short paper which was remarkable for its lucidity and completeness. In February of 1896 the lecturer had seen some of the early attempts of Sir Oliver Lodge "to take radiographs," the subject being a boy with a pistol bullet in his wrist. After several failures a successful radiograph was obtained; the exposure was one and three-quarter hours, and, as the lecturer characteristically remarked, "Providence alone is to be thanked that no  $x$ -ray burn followed."

Mr. Holland then gave an account of his early experiences in  $x$ -ray work. He said: "At the end of May, 1896, I was the proud possessor of a 3-inch spark coil, six Grove cells, and a tube without an anticathode." They survived only a few days, being replaced by accumulators and a Jackson focus tube. At this very early date "Professor Herbert Jackson made possible by this one tube improvement all the beautiful radiographs which we see at the present time."

Mr. Holland then gave an account, with illustrations, of his own work in the early days of radiography, done with an apparatus which cost £30, including the tube. He related that as early as October 2nd, 1896, two boys with coins in the oesophagus were examined; the coins were found and removed. One of the coins had been in the throat for just over a year. The child had been treated for tuberculosis, and had been to many specialists and health resorts. Within a few weeks of the removal of the coin his cough and all his other symptoms had entirely disappeared. Mr. Holland cited this as "one of the first great  $x$ -ray triumphs of diagnosis." He related how in November, 1896, he examined his first chest case, and in December "my notebook reports that a stomach case was examined, and that the exposure given was one hour."

He gave many examples of the trials and troubles in the early days of radiography, and of how these were successfully overcome. Mr. Holland believed that the influence of  $x$  rays as regards accurate diagnosis was even yet not altogether realized, and proceeded to trace the development of radiography in the investigation of the various systems of the body.

*Diseases of Bones.*

He first dealt with the bony skeleton, and showed how from the very first all conditions affecting it had been recognized as a "fair field for  $x$ -ray diagnosis. . . . The demonstrations of fractures, dislocations, and of disease and abnormalities as they affect bones is such an everyday  $x$ -ray necessity that it has altogether ceased to be a wonder, and the examinations are made as a matter of course." The lecturer emphasized the value of radiography in injuries adjacent to and affecting joints in the demonstration of cracked fractures of bones in injuries to the small bones of the hand and foot, and showed how the accuracy of diagnosis, wholly impossible in the pre- $x$ -ray days, had a great influence on final results.

The results of  $x$ -ray examination of bone conditions became of greater and greater importance as experience increased; there was no disease affecting bones, whether intrinsic or extrinsic, which did not, in its course, give rise to some  $x$ -ray

change from the normal. In many cases in which the clinical diagnosis was doubtful, the  $x$ -ray findings became conclusive. He showed, however, that one unfortunate result of this universal application of radiography was the tendency, more particularly in out-patient departments, to rely to such an extent upon the  $x$ -ray diagnosis that the cases were not properly examined by the student; he emphasized the importance of a thorough clinical examination in addition to the  $x$ -ray examination.

*Foreign Bodies.*

He then proceeded to deal with the methods of detection and localization of foreign bodies, paying a just tribute to the work of the late Sir James Mackenzie Davidson.

*Diseases of the Urinary Tract.*

The lecturer dealt next with the urinary tract. The modern surgery of stone in the kidney and ureter had been the direct result of  $x$ -ray diagnosis; the first kidney stone shown, and later removed by operation, was reported by Dr. MacIntyre of Glasgow in July, 1896. Mr. Holland gave his own experience in this branch of the work, and stated that at the present day "radiography is the only method of examination which can be relied upon to demonstrate the presence of stone in kidneys or ureters. All other diagnostic methods are merely assistant to  $x$  rays in the interpretation of doubtful shadows. Radiography is the stand-by of physicians and surgeons. By showing the size, shape, and position of a stone it will often decide the question of medical or surgical treatment. . . . The salient feature of radiography is not the showing of the shadows of those stones—that is an easy matter; it is the difficulty, indeed sometimes the impossibility, of making an accurate differential shadow diagnosis. He gave several examples of exceptional cases, and spoke of the use of the opaque catheter and the injection of an opaque solution into the ureter and kidney. It has been the custom in Liverpool at the Royal Infirmary for many years to place almost implicit confidence in the  $x$ -ray examination, be it positive or be it negative: at the same time always remembering that in the negative cases the possibility of a small uric acid stone must be borne in mind; and also that in a certain number of cases which show suspicious shadows only, errors of interpretation must occasionally occur, which, in some cases at any rate, are not preventable. . . . Exploratory operation for kidney stone is a thing of the past: this is the triumph of  $x$  rays in the diagnosis of stone."

*Thorax: Pulmonary Tuberculosis.*

In dealing with the examination of the thorax by the  $x$  rays Mr. Holland showed how the present position had not been established without a somewhat bitter fight. He said: "It has taken time to convince the majority of physicians that radiography can disclose with accuracy what cannot be detected by auscultation and percussion; but fact after fact disclosed by  $x$  rays—striking pictures of pathological conditions, quite unsuspected—occurring day after day, could not be pushed upon one side, and it is now admitted by most physicians that gross intrathoracic lesions may be present which are not diagnosable by the ordinary method, but which  $x$  rays reveal at a glance in a most dramatic manner." He gave numerous instances of such cases.

The subject of pulmonary tuberculosis was carefully reviewed, and the lecturer gave his definite conclusions:

1. The clinical diagnosis of pulmonary phthisis is in many cases a mere matter of conjecture, one which is not proven by physical signs, and one on which the history of the case has a very significant bearing.
2. That in many cases—and I emphasize the many—in which physical signs are reported to me as being entirely or almost entirely absent,  $x$  rays disclose a condition of such extensive disease that at the first sight it seems incredible.
3. That in any case of recognized lung tuberculosis the  $x$ -ray examination will inevitably reveal more than the most skilled clinician without  $x$  rays can arrive at.
4. The negative value of a properly conducted  $x$ -ray examination is of the very greatest value.

*Gastro-intestinal Tract.*

The historical aspect of the  $x$ -ray investigation of the gastro-intestinal tract was briefly outlined. The lecturer proceeded to describe the triumphs of radiology in the differential diagnosis of oesophageal and gastric conditions. The influence of  $x$  rays in the diagnosis of intrinsic and extrinsic diseases affecting the oesophagus was discussed, and the

question of the x-ray diagnosis of gastric ulcer dealt with. The lecturer entirely agreed with the statement of Sir Berkeley Moynihan that "in the diagnosis of gastric ulcer it has pride of place, in competent hands it is far more accurate than any other method of diagnosis, clinical or chemical, or than all other methods combined." Mr. Holland, in speaking of gastric ulcer, stated that he had seen over 200 cases of hour-glass stomach of every possible variety. Very few had been diagnosed previous to the x-ray examination. The importance of x-ray examination in all cases of chronic dyspepsia was emphasized, and many illustrative cases were given. He concluded his lecture with a word of warning. He thought that in teaching hospitals a little too much is at present being asked from radiologists. They were often expected to make a diagnosis from the x-ray examination alone; this he considered was not fair, and not calculated to advance either the art of radiology or that of medicine.

#### Conclusion.

X-ray examination was one method used for arriving at a correct diagnosis, and although it was both dramatic and final in many cases in others it was to a large extent influenced in its reading by a knowledge of other facts. "Students are being taught to rely too much upon the x-ray departments for their diagnosis, and are neglecting to develop to its full the art of observation and deduction so wisely used by their ancestors."

X rays, he went on to say, have crossed the paths of medicine in every direction, and wherever they have crossed those paths they have left behind beacons of light.

### THE IMPORTANCE OF EARLY DIAGNOSIS IN PULMONARY TUBERCULOSIS.

It is a very favourite occupation of enthusiasts in personal and general hygiene to calculate the annual number of deaths which might be averted if only more enlightened principles could be inculcated into the people and a higher standard of sanitation be realized in their environment, as, for instance:—To what extent the infantile mortality might be reduced if a perfectly safe milk supply could be ensured? What would be the effect on the longevity of the workers were certain factory defects removed? How many lives would be saved in tropical countries if the tsetse fly could be exterminated or the mosquito banished beyond the confines of man? And so on. A very interesting and inspiring pursuit, and one which, by appealing to the imagination of the enlightened, has probably provided a considerable stimulus to the carrying through of valuable reforms in the prophylactic treatment of disease.

The publication by the Medical Research Council of a report on tuberculosis in insured persons accepted for treatment by the City of Bradford Health Committee<sup>1</sup> might well engender an attempt on the part of some of the more speculative members of the community to estimate the yearly saving of lives in the British Isles if all patients developing pulmonary tuberculosis could be diagnosed in the early stages of the disease. Though tempted to give way to a similar impulse ourselves, we feel it better to direct our activities into a more didactic channel, and to give a brief account of the results which have been obtained by Dr. Vallow in the treatment of the poorer social classes affected with tuberculosis at Bradford. In the years 1914-16 the number of persons accepted by the Health Committee for treatment of pulmonary tuberculosis was 584 (342 men and 242 women). These figures comprised patients in all stages of the disease, and were not selected in the way that patients for sanatorium benefit usually are. For the early, and the more hopeful of the moderately advanced cases, sanatorium treatment was adopted; for the advanced cases hospital treatment was given as a preventive measure; and for certain other cases domiciliary treatment was provided. Added to this, the after-care of discharged institutional patients was effectively attended to by health visitors and others, and extra food and clothing were provided for such cases as required it.

Owing to the fact that Bradford forms a complete civic unit, the following up of the patients and the ascertaining of the number of deaths which occurred has been comparatively easy—so much so that only 3.9 per cent. of the patients have

been lost sight of. The statistics collected with regard to their after-history have been completed, yielding information for an average of five years in the case of those patients who survived. The classification adopted was similar to that of the Association for the Study and Prevention of Tuberculosis in America, with certain differences to be noted later. The results of a careful analysis of the figures show that of 204 Stage I cases only 3.4 per cent. died; of 158 Stage II cases 55.1 per cent. succumbed; and of 222 Stage III cases the mortality was no less than 99 per cent. If the actual deaths amongst the Stage I cases be compared with the expected deaths amongst the general population of England and Wales—calculated by multiplying the "exposed to risk" by the ratio of mortality for the approximate ages according to the English Life Table No. 8—it is found that the patients in this category enjoy a practically normal after-lifetime. A comparison of the Bradford figures with those of the Midhurst report (Spec. Rep. Series, No. 33) shows that the Stage I cases in the former series do rather better, the Stage II cases much the same, and the Stage III cases, for obvious reasons, very much worse.

These, quite briefly, are the results obtained. There are one or two points to be noted. First, as regards classification. Though the standard adopted was similar to that employed at Midhurst there are certain differences. For instance, in the Bradford Series Stage I cases were restricted to those showing very limited signs confined to not more than one lobe, whereas in the Midhurst series slight infiltration of both apices was permitted. Again, in the former series, to qualify for Stage III a patient had to show extensive signs in three or more lobes, while in the latter series extensive infiltration or consolidation in one or more lobes was required. This means that on the Bradford classification a patient might have disease of the whole of the left lung, and be absolutely moribund, and yet, since only two lobes were affected, he would have to be relegated to Stage II. True, it is unusual to find such extensive disease in one lung without at least some trouble in the opposite one, yet such cases do occur—as all those familiar with artificial pneumothorax treatment will admit. These differences do undoubtedly detract from the value of an exact comparison between the Bradford and Midhurst figures. Again, in calculating the mortality rate, in the Midhurst series all deaths were counted—no matter from what cause—while in the Bradford series, it appears—though the author does not give very definite information on the point—that only those dying from pulmonary tuberculosis were included. Lastly, it is unfortunate that no classification based on the presence or absence of tubercle bacilli in the sputum was made in the Bradford cases.

Leaving aside these points, however, there is a big fundamental fact which stands out pre-eminent—namely, that patients developing pulmonary tuberculosis who are diagnosed in the early stages of the malady, who receive adequate sanatorium treatment, and who then return to their work in the industrial town in which they primarily contracted their disease, enjoy, for all practical purposes, a normal after-lifetime. This is a fact, and amidst the tangled skein of conflicting opinions regarding the treatment of phthisis it is a fact to be firmly grasped. It is a fact which should serve as a guide in the subsequent attitude of the health authorities towards the prevention of tuberculosis. It is a fact which should stimulate every medical practitioner to do his best to recognize the disease before it is yet too late. It is a fact which all those who oppose the present sanatorium treatment of pulmonary tuberculosis have got to face. And it is a fact which should give encouragement to all those whose endeavours have been directed towards providing a rational treatment for the disease—a treatment, moreover, which comprises not merely a few months' rest and training at an institution, but which recognizes the importance of enlisting the help of the social workers so as to ensure the prolonged after-care of the patient and the provision of the best hygienic conditions which the circumstances will allow.

There has been published in *The World's Health* (a monthly review issued by the League of Red Cross Societies) an account of the conference of Oriental Red Cross Societies, held at Bangkok, Siam, towards the close of last year. The conference was presided over by Sir Claude Hill, director-general of the league, who together with Dr. Malcolm Smith acted as delegates of the British and Australian Red Cross. Dr. Norman White represented the League of Nations, Dr. M. E. Butler the Rockefeller Foundation, and Dr. W. W. Peter the Council of Education in China.

## England and Wales.

### PSYCHOLOGICAL MEDICINE AND RESEARCH AT BIRMINGHAM.

SIR FREDERICK MOTT has taken up his new duties as honorary director of the pathological laboratories of Birmingham City Mental Hospitals, and gave the first of a series of lectures on body and mind at the university on April 26th. Principal C. Grant Robertson, who presided, said that in 1919 Sir Charles Hyde generously founded a lectureship in psychotherapy; a single lecture had been delivered each year by a different lecturer. When, mainly through the instrumentality of the vice-chancellor, Sir Gilbert Barling, negotiations with the Asylums Committee resulted in the provision of funds for research work, the annual lectureship had been converted into one in morbid psychology tenable for three years, and this post had been accepted by Sir Frederick Mott, who, in addition to giving general supervision of the laboratories at his weekly visits, would give a course of lectures. It was hoped that the scheme for research in mental diseases would eventually be extended, and that other public authorities of the Midland area would join and would contribute to its funds and to the facilities for study. Sir Frederick Mott said that he had hoped that another university would have adopted a scheme similar to that instituted in Birmingham, but in this he had been disappointed, and London was without a university school such as had been established in Birmingham. In foreign countries the university would always be found associated with a mental hospital, and a great part of the valuable work coming from Germany in neurology and psychology had been due to that association. There the professor of psychology at the university was nearly always superintendent of the mental hospital.

### BRITISH HOSPITALS ASSOCIATION.

The annual conference of the British Hospitals Association will be held in Sheffield on May 31st and June 1st, under the presidency of the Hon. Sir Arthur Stanley. The first business of the conference will be to consider the reference from the last annual meeting concerning the establishment of a central fund for the provincial hospitals. Mr. H. J. Waring, F.R.C.S., Vice-Chancellor of London University, will then deliver an address on "The future of voluntary hospitals from a medical viewpoint," which will be followed by a discussion. In the afternoon there will be a discussion on modern hospital administration, in which Dr. S. S. Goldwater, of Mount Sinai Hospital, New York, will take part. A reception will be held later in the afternoon at the town hall by the Mayor of Sheffield and Sir Henry Hadow, Vice-Chancellor of Sheffield University, and in the evening there will be an official dinner to the delegates at the Royal Victoria Hotel, with Sir Henry Hadow in the chair, and Lord Onslow, chairman of the Voluntary Hospitals Commission, as the principal guest. On the following day the business meeting will be held. Hospital finance will thereafter be discussed; an opening statement will be made by Sir Napier Burnett, Lord Hambleton will give an address on hospital finance in its relation to approved societies, and a discussion will follow. The Master Cutler, Mr. R. W. Matthews, will give a luncheon at the Cutlers' Hall to the speakers and the council of the British Hospitals Association and other leading members of the conference. In the afternoon arrangements have been made for visits to the different hospitals and convalescent homes in the neighbourhood. Official programmes for the conference will shortly be obtainable from the regional secretary, Mr. S. R. Lamb, Sheffield Joint Hospital Council, St. Peter's Close, Sheffield.

### THE CARE OF THE INSANE IN LONDON.

In a report presented to the London County Council on April 24th the Mental Hospitals Committee discussed the conclusions of the Ministry of Health Committee which recently investigated Dr. Lomax's charges against asylum administration. Of the ten mental hospitals belonging to the London County Council, three—Hanwell, Colney Hatch, and Banstead—date back for about ninety, seventy, and forty years respectively, and in their older parts do not conform to modern ideals. The Committee states, however, that classification of patients, which is more readily carried out in modern buildings, is the rule in all the London mental hospitals so far as structure permits. At each hospital a deputy medical superintendent relieves the medical super-

intendent of certain executive duties. The medical superintendents meet the assistants every morning in consultation. Every opportunity is afforded for patients to have private interviews with members of the medical staff. The charges made by Dr. Lomax with regard to prescribing and administration of medicines have no applicability to the London mental hospitals. Facilities exist at all the hospitals for hospital and surgical treatment, and the services of specialists are obtained when considered necessary. The Committee is satisfied that no patients who are fully recovered are detained, but has some doubt whether patients may not be too readily discharged on the application of friends. Every effort is made by up-to-date treatment to bring about recovery. Employment in suitable cases, as well as amusement, is provided, and therapeutic occupation is being considered. With regard to those criticisms by Dr. Lomax for which the Departmental Committee said there was some ground—namely, the number and training of assistant medical officers, the number and training of nurses, and the monotony of diet—the London County Council Committee states that at all its large mental hospitals there is authority to employ, in addition to the medical superintendent, eight medical assistants, many of whom possess a special diploma in psychological medicine; it is a condition of the Council's nursing service that nurses shall train for and obtain the nursing certificate of the Medico-Psychological Association before taking rank as staff nurses; improvements in dietary are being considered, and authority has lately been obtained to make certain meals more appetizing. It is agreed that in classification some account should be taken of home conditions and surroundings, though the mental state of the patient is the chief factor upon which classification must be decided. It is agreed also that preference in future appointments should be given to candidates possessing a diploma or degree in psychological medicine, and that it is desirable that superintendents shall have held a general hospital appointment. Seclusion, it is thought, requires a more precise definition by the Board of Control (a recommendation to that effect was agreed to by the Council), but at the same time the Committee is satisfied that there is no abuse of seclusion at the London mental hospitals. The organization of after-care work needs to be considerably strengthened and extended; and the Committee concurs in the opinion that the provision of facilities for the early treatment of incipient mental disorder without certification would be of great value to the community. In this connexion reference is made to the Maudsley Hospital. The Committee concludes its report by stating that it is anxious that the natural concern of the friends of the patients in its charge (over 18,000) should not be aggravated by groundless apprehensions as to their treatment.

## Scotland.

### EDINBURGH SUMMER POST GRADUATE COURSES.

The syllabus of post-graduate courses to be given at Edinburgh in July, August, and September has been issued. These courses were first given in 1906, were repeated annually till the outbreak of the war, and were resumed in 1919. Though the organization of the various courses and the numbers of graduates attending them have not yet reached the high-water mark of 1913, the present year's syllabus shows a marked advance upon that of any year since the war.

The first course this year is in obstetrics and gynaecology. It will last four weeks, will begin on July 16th, and will comprise clinical midwifery (one hour daily at the Maternity Hospital), clinical gynaecology (two hours daily in the Royal Infirmary), child welfare and ante-natal clinics, and demonstrations of obstetrical and gynaecological pathology. The fee for this course is ten guineas.

A special course on diseases of children will be held from July 30th to August 10th. It will consist of clinical demonstrations on the common and important medical and surgical conditions of infancy and childhood, supplemented by eight lectures on special subjects. Preventive medicine in relation to childhood is also included in ante-natal clinics, child welfare clinics, dental clinics, and venereal disease clinics. The fee for this course is six guineas.

A general medical course, lasting four weeks (from August 13th to September 8th) will fill up practically the whole day from 9 a.m. to 4 p.m. The examination of the

various systems is taken up by members of the Royal Infirmary medical staff as follows: Circulatory system, Dr. W. T. Ritchie; respiratory system, Dr. Fergus Hewat and Dr. H. Whitridge Davies; renal and alimentary systems, Dr. R. A. Fleming and Dr. John D. Comrie; nervous system, Professor Edwin Bramwell; ductless glands, Dr. John Eason; blood, Dr. A. Goodall. There are also clinics upon general medical diseases, infectious diseases (Dr. Claude Ker), dermatology (Dr. Cranston Low and Dr. F. Gardiner), diseases of the eye, diseases of children, venereal diseases, and tuberculosis; as well as demonstrations of medical anatomy, medical side-room work, *post-mortem* examinations, morbid anatomy, and medical radiology.

A general surgical course will run concurrently with the medical course and occupy the same hours daily. The following departments of surgery will be taken up individually: General surgery, Mr. John Fraser; surgery of the kidney, Mr. Henry Wade; abdominal surgery, Mr. Chiene and Mr. Wilkie; venereal diseases, Mr. David Lees. There are also surgical and gynaecological operations and surgical clinics in the Royal Infirmary and Royal Hospital for Sick Children, and demonstrations on surgical anatomy, surgical pathology, and surgical radiology.

A set of special lectures on subjects of general medical and surgical interest have been arranged for those attending the two last-mentioned courses, and include—

Surgery of the large intestine, by Sir Harold Stiles; Diagnosis of biliary infections, by Mr. Wilkie; Estimation of renal efficiency, by Dr. J. D. Comrie; Labyrinthine and intracranial complications of middle-ear suppuration, by Mr. J. S. Fraser; Common disabilities of the foot, by Mr. John Fraser; Mechanism of certain cranial deformities, by Mr. D. M. Greig; The Schick reaction and diphtheria immunization, by Dr. C. B. Ker; Sensitization phenomena in diseases of the skin, by Dr. R. Cranston Low.

During the period of the general courses the following special courses may be attended, at hours to be arranged, by those desiring to do so: Diseases of the Blood, Vaccine Therapy, and Physiological and Biochemical Methods in Clinical Medicine. It is also pointed out that during the summer term (May to July), before the ordinary post-graduate courses begin, there are numerous courses suitable for graduates—namely, Medical Entomology and Parasitology, Diseases of Tropical Climates, Psychology and Experimental Psychology, Neurology, Chemical Physiology, Tuberculosis, Clinical Therapeutics, Venereal Diseases, Surgical Pathology, and Diseases of the Nose, Throat, Ear, and Larynx.

Application for enrolment or for details of the courses should be made to the Secretary, Post-Graduate Courses in Medicine, University New Buildings, Edinburgh.

#### GLASGOW: CLINICAL MEETING.

The clinical meeting of the Glasgow and West of Scotland Branch of the British Medical Association was held in the Western Infirmary on the afternoon of Tuesday, April 24th, and tea, through the kindness of Dr. D. J. Mackintosh and the managers, was served in the conservatory on arrival. The clinical demonstrations commenced at 4 p.m. and continued until 6.15. They proved most interesting and instructive, and embraced an unusual number of rare conditions. At the close of the demonstrations very hearty votes of thanks were, on the motion of the President of the Branch, Dr. G. Douglas McRae, accorded to the managers and Dr. Mackintosh, and to the medical and surgical staffs, for the trouble they had taken in providing such an interesting and educative programme. The attendance was 115. Thereafter an adjournment was made to the Grand Hotel, where dinner was served under the chairmanship of Dr. G. Douglas McRae. The guests present were Dr. John Stevens (Chairman, Scottish Committee), Dr. J. R. Drever, Scottish Medical Secretary, and Mr. Andrew S. Barr. After dinner and the toast of the King, the Chairman called on Professor Stockman to present the Association prize of £10 to Mr. Andrew S. Barr for the best essay of 5,000 words sent in by students of the Glasgow medical schools on the diagnosis and treatment of jaundice arising from obstruction of the larger bile ducts. The toast of the Branch was proposed by Dr. Drever and responded to by the Chairman. Other toasts followed. During the evening a varied programme of songs and stories was carried through, which added greatly to the enjoyment of the fifty

## Ireland.

### SUPERANNUATION ALLOWANCES.

THE Ministry of Local Government (Irish Free State) has addressed a letter to the Dublin Corporation with regard to the superannuation allowances for its officials; it will be of much interest to medical officials, who either have recently retired from the public services or are about to do so. In the course of the letter it is pointed out that the principles to be observed in granting pensions are:

(1) Pension should run from the date on which employment definitely ceased.

(2) Normally 1/60th for each completed year of service, with a maximum of 40/60ths.

(3) No pension for employees of less than 60 years of age, or with less than the period of service prescribed by statute, except—

(a) In cases of permanent incapacity if the statutory period of service has been completed, but the age of 60 has not been attained.

(b) In specially meritorious cases the nominal rate may be increased by the addition of extra years' service not exceeding one-third of the service, but subject to a maximum of two-thirds.

(4) In the case of wage-earners distinction must be drawn between substantive wages and additional war wages, and in the case of salaried officials in regard to bonus. An addition to the pension calculated on the bonus may be allowed subject to half-yearly revision in accordance with the cost of living scale.

If preferred, the Ministry would agree to 75 per cent. of the current cost of living, bonus being included in the substantive salary for the calculation of a fixed pension. No emoluments in the shape of overtime or extra duty pay, or other casual remuneration, are to be regarded as pensionable.

(5) Pensions to be calculated according to statute on the average of the wages of the three preceding years, or on the remuneration at the time of resignation.

### ROYAL ACADEMY OF MEDICINE IN IRELAND.

The centenary of Pasteur was celebrated by a meeting of the Academy of Medicine in Ireland at the College of Physicians. Sir Arthur Chance was in the chair, and an address on Pasteur was delivered by Dr. William Fearon, Sc.D. Among those present were Dr. M. F. Cox, President of the College of Physicians; Sir William Wheeler, President of the College of Surgeons; the Most Rev. Dr. Bernard, Provost of Trinity College; and Sir William Thompson. The first ceremony, however, was to confer the honorary fellowship of the Academy on Professor E. Hastings Tweedy. Dr. T. P. C. Kirkpatrick formally presented Professor Tweedy, who, he said, had won both for the Academy and himself an honoured name throughout the world. As Pasteur had taught how to prevent and cure hydrophobia, so Ernest Tweedy had taught how to control that almost equally terrible disease eclampsia, which too often killed both the mother and her unborn child. In the long roll of Irish physicians no name ranked higher than that of Ernest Tweedy. The announcement was received with acclamation.

The Chairman, in making the presentation, said that in one branch of the medical art Dublin held the foremost place; her fame in obstetric medicine was known all over the civilized world. By his original and very valuable investigations, his lucid teaching and his public work, Dr. Tweedy had advanced and maintained the reputation of the Dublin school of medicine. For that they owed him a debt of gratitude, and now they were trying to pay a little of their debt by conferring upon him the highest honour and distinction within the power of the Academy to give; to emphasize the dignity, the presidents of both colleges were present. He hoped that the ceremony would be a happy augury of the time when, strife and destruction over, Irish men, with their destinies in their own hands, would commence the work of reconstruction. In that work the medical profession would have a heavy responsibility; while the work appertaining to legislative change fell upon other shoulders, there were many problems which could only be solved by the best brains in their profession.

Professor Tweedy, in the course of his reply, said that he fully appreciated that the Academy of Medicine had conferred upon him the greatest honour within its power and having said that he felt that ambition required no further stimulus. If the honour could be enhanced it had been enhanced by allowing it to fall upon the day on which the Academy celebrated the centenary of one of the greatest scientists of his time, Louis Pasteur.

## South Australia.

[FROM OUR CORRESPONDENT.]

### MEDICAL LEGISLATION.

THE last session of the State Parliament was happily barren so far as medicine and the allied professions are concerned, nor have all the eggs laid by the legislative goose in former years yet been hatched. The Venereal Diseases Act of 1920 may almost be considered a "dud," for the Regulations under the Act necessary to put it into force have not yet been gazetted, possibly have not yet been drafted. Medical reformers and legislators who so eagerly demanded legislation seem, nevertheless, to be satisfied. In medical circles, however, a determined attempt is being made to have some reform of the maternity bonus. It is generally recognized that it does no particular good to mother or baby, but this, curiously enough, was never suggested by the Labour party, at whose behest it became law, after being turned down by their caucus a few months previously; it was undoubtedly a political bribe. It now costs Australia about three-quarters of a million a year, and the force of the argument (prophetically advanced many years ago by Dr. Hone) that the money might be spent to greater advantage by providing pre-maternity clinics and making a real attempt to lessen neonatal and infantile mortality is beginning to be appreciated.

### THE UNIVERSITY AND MEDICAL SCHOOL.

Two handsome bequests have been made for the benefit of the medical school—one of £30,000 by the late Mrs. Marks and the other of property worth at least £20,000 by the late Miss Keith Sheridan, the daughter of an Edinburgh M.D. who came out to Adelaide many years ago, not to practise medicine, but as a journalist. The University Council is considering the relative claims of research and of the foundation of additional chairs, or of medical units, but no plans are yet matured. To justify the devotion of some portion of this income to research, it may be mentioned that Professor Brailsford Robertson has succeeded in manufacturing in the Biochemical Laboratory a preparation of insulin the efficiency of which has already been proved by Dr. De Crespigny in some of his cases.

In the medical school there are no important changes, nor on the staff of the principal hospitals, but there is quite an influx of returned post-war graduates, who besides their military decorations bring with them the F.R.C.S. Eng. or the M.R.C.P. Lond.; it is hoped that openings may be found for their energies. Sir Joseph Verco leaves this week to represent the University at the octocentenary of St. Bartholomew's Hospital, where he was a distinguished student.

### THE BRITISH MEDICAL ASSOCIATION.

The Branch flourishes and increases in numbers. It is eagerly expecting the advent of incorporation, so that arrangements may be made whereby it can become possessed of the British Medical Hall. The limited company which owns the property has declared a dividend for the first time, and it is hoped that it may be handed over to the Branch some day free of mortgage. The Listerian oration this year was delivered by Dr. Rothwell Adam, the Emeritus lecturer on obstetrics and gynaecology in the University of Melbourne. The indebtedness of obstetrics to Lister was admirably brought out, and the address was much appreciated. The President of the Branch this year is Dr. T. G. Wilson, the lecturer on gynaecology at the University.

## India.

### DINNER TO SIR TEMULJI B. NARIMAN.

SIR TEMULJI B. NARIMAN, Sheriff of Bombay, was the guest of honour at a dinner on March 13th given by members of the medical profession in Bombay to celebrate his golden jubilee as a medical practitioner. Major-General W. E. Jennings, Surgeon-General to the Government of Bombay, was in the chair, and some seventy-five medical men, representing the different communities, took part in the celebration. General Jennings presented Sir Temulji Nariman with a silver salver, on which the names of his medical colleagues were to be inscribed.

### MILITARY MEDICAL SERVICES.

From an announcement made in the Indian Legislative Assembly, on March 16th, it would appear, according to the *Pioneer*, that the Government has under serious consideration the proposals made by the Escher Committee for the future organization of the military medical services. The Committee recommended that the post of Director of Medical Services should be held alternately by an officer of the Royal Army Medical Corps and the Indian Medical Service. Mr. Burdon said that acceptance of this recommendation would prevent the amalgamation of the appointments of the Director of Medical Services and the Director-General of the Indian Medical Service. The Inchcape Committee apparently considered the possibility of this amalgamation, but found it impracticable as a means of securing economy. Mr. Burdon said that the Director of Medical Services could not give the time required to discharge the duties of the Director-General of the Indian Medical Service in addition to his own.

### SURGERY IN MYSORE.

The report for 1921 of the Krishna Rajendra Hospital, Mysore, shows that work of a high standard, particularly in surgery and gynaecology, is being carried out in that hospital. During the year 2,845 in-patients and 56,754 out-patients were treated, while 1,048 major operations and 594 minor operations were performed on in-patients, and 779 minor operations on out-patients. Notes on a number of the more important cases are included in the report, and some of the accounts of extensive gynaecological procedures show that excellent results were obtained. Dr. Mahomed Usman, superintendent of the hospital, deserves commendation for the good work done under considerable difficulties.

## Correspondence.

### COLLOIDAL PREPARATIONS.

SIR,—In view of the conflicting statements made by Sir William Pope and Professor Clark as to the properties of certain preparations professing to be of a colloidal nature, it may be worth while to give my own experience with a sample of "collosol ferrum." This was bought at Messrs. Martindale's, and the price paid was five shillings for four ounces. It was a clear liquid of a slightly brown colour, such as a very weak colloidal solution of ferric hydroxide would have, although tests by dialysis—to be referred to presently—suggested that the colour had another source, possibly the glucose which Sir William Pope states to be present. Glucose, unless chemically pure, usually gives brown solutions.

The solution was strongly acid—10 c.cm. required 3.1 c.cm. of N/10 sodium hydroxide to neutralize it to phenolphthalein. Thus it was even more acid (about N/30) than the specimens examined by Professor Clark; and, one would imagine, not very satisfactory for intramuscular injection. Ferric hydroxide can, of course, exist in an alkaline solution, provided that a protective agent is present. In acid solutions the sugar and gelatin are superfluous. It is interesting to note that ferric chloride solutions remain slightly acid even when shaken with freshly precipitated ferric hydroxide.

In the next place, my sample of "collosol ferrum" gave a deep blue colour with potassium ferricyanide, a faint blue with the ferrocyanide, thus agreeing with those of Professor Clark. It gave also a precipitate with silver nitrate and nitric acid. A preparation which I made for class purposes in Graham's manner by shaking a dilute solution of ferric chloride with freshly precipitated and washed ferric hydroxide in excess, gave no reaction with either ferricyanide or ferrocyanide, which is the normal behaviour. If such a solution is precipitated by sodium sulphate and filtered, the filtrate gives no colour with thiocyanate. The ferric ions present are in such low concentration as to be undetected by this delicate test. It is well known that a trace of ferric chloride is necessary for the stability of these sols, but it is present in the non-ionized state, adsorbed by the particles of ferric hydroxide.

But the presence of ferrous or ferric ions does not exclude the possibility that there might be iron in the colloidal state in addition. To test this I submitted the "collosol ferrum" to dialysis against water through a membrane of parchment paper. After two days, equal volumes of the solutions inside and outside the membrane were treated with hydrochloric

acid and zinc in the usual manner, in order to convert any ferric salt present into ferrous chloride and to dissolve any in the colloidal state. Both solutions became clear and nearly colourless, and gave no reaction with thiocyanate. On addition of ferricyanide both became deep blue, and I was unable to detect any difference in the intensity of the colour. If there had been any indiffusible iron in the original preparation, the contents of the dialyser would have contained more total iron than the dialysate. I am bound to conclude that if there was any iron in the colloidal state in the original solution it was only in extremely minute amount. In connexion with Sir William Pope's remarks about the variety of dimensions of the pores in ultra-filters, it is only fair to remember that Professor Clark tested his membranes with congo red, and that my parchment paper was known to be impermeable to this dye, whose particles are too small to be resolved by the ultra-microscope.

As to the presence of particles visible under the ultra-microscope, I have in another place called attention to the fallacy of this test unless account is taken of the concentration of the solutions. It may be to the point here to mention that I found a colloidal solution of the acid of congo-red which contained only one part by weight in about 200 of water had to be diluted 1,300 times before the particles were sufficiently far apart to be seen separately and counted. "Collosol ferrum" ought to be crowded with particles when diluted 130 times. The appearance of a large number in the undiluted state could be accounted for by a trace of colloidal material. It is scarcely necessary to remark that the apparent close packing of the particles is due to their actual size being far less than it seems to be, owing to the large diffraction rings.

Since, as Graham showed, one of the properties of colloidal ferric hydroxide is precipitation by sodium sulphate it would have been possible to make a further test of "collosol ferrum" if protectives had not been added unnecessarily. As it is, however, the absence of a precipitate might be attributed to the presence of sugar and gelatin and would not prove the absence of the colloid.

If the iron were in the colloidal state in this preparation a bottle of four ounces would only contain a single dose, as pointed out to me by Professor Cushty. It is true that claims are made that remedies in the colloidal state are greatly more effective than in true solution, but the evidence is very doubtful, and in any case "collosol ferrum" contains little or no colloidal iron. It is a somewhat costly preparation at five shillings the dose, whatever its nature.

I take it that in the particular case of iron the therapeutic object is to avoid the astringent action of the ionized salts on the stomach. Now these are absent in solutions made in Graham's manner and probably also in the commercial "dialysed iron." But I have not tested the latter.

For purposes of intravenous or intramuscular injection, if such modes of administration of iron are really necessary, it would seem advisable to possess solutions of neutral or slightly alkaline reaction. So far as I am aware, these are only stable in the presence of rather high concentrations of alkali. But this might be overcome by appropriate inert protectives, such as sugar. Sir William Pope reminds us of Graham's observations on this point.

As to the controversy which has excited this lengthy letter, I can only conclude that if Sir William Pope's "colloidal ferrum Crookes" is another name for "collosol ferrum," the preparation which he had in his hands was a different one from those sold to the public. That sold to me was similar in its properties to those tested by Professor Clark.—I am, etc.,

W. M. BAYLISS.

London, N.W.3, April 28th.

SIR,—Sir William Pope does me the honour of quoting my name in support of the dignified rebuke which, in your issue of April 28th, he administers to my friend Professor Clark. There are many, no doubt, who have deplored Professor Clark's display of that modernist, scientific spirit, which is so insidiously undermining the reverence for authority, at one time the sure foundation of medical belief. To all such it is a real encouragement to see your columns opened once more to a statement like that of Sir William Pope, made with such calm resistance to the challenge of presumptuous experiment.

But Professor Clark, alas! is rebellious and unrepentant. He still questions, on the strength of his own experiments, the accuracy of a statement which, as Sir William Pope points out, "has never before been impugned." Could scientific

presumption go further? Alas! it could. Sir William Pope states that a solution is alkaline; Professor Clark dares not only to assert that it is acid, but to suggest that the question can be settled by a vulgar appeal to litmus paper.

Let us hope, Sir, that Professor Clark, and the British Medical Association which has too thoughtlessly encouraged him, will see the error of their ways, and will abandon such attempts to assert the authority of the experimental method against that of innumerable assertions and advertisements, and, now, of a pronouncement *ex Cathedra Chemica Cantabrigiense*.—I am, etc.,

London, N.W., April 28th.

H. H. DALL.

#### SPACE JUDGEMENT WITH ONE EYE.

SIR,—The very interesting article on monocular and binocular vision by Dr. T. Stewart Barrie, read at the Glasgow Meeting (BRITISH MEDICAL JOURNAL, December 30th, 1922, p. 1260), together with the discussion thereon, opens up a wide view of a subject on which hitherto there has been much misconception. Ophthalmologists and others possessed of binocular vision have laid great stress on the necessity of its possession in order to obtain a stereoscopic effect with its consequent advantage in the judgement of distances and relative positions in space of objects seen. This view appears to have been reached mainly by testing persons who were accustomed to binocular vision by occluding one eye.

As Dr. Stewart Barrie rightly points out, however, people who have long been accustomed to monocular vision have really got the stereoscopic sense, and are as accurate in judgement of distances for ordinary purposes as those with binocular vision. He instances the common fact that a man with one eye can drive a motor car through a crowded street with as much ease as a man with two eyes.

In the next sentence he states that "aviators, for example, should have binocular stereoscopic vision." It is this last sentence in which he appears to me to be inconsistent. Surely the requirements in stereoscopic vision and in the accurate judgement of distances and positions on the part of a motor driver in crowded traffic are far greater than those of an aviator. In any case, it seems to me exceedingly difficult, on any theoretical considerations, to suppose that the parallax or convergence due to the eyes, being some six centimetres apart, could be sufficient to aid appreciably in the judgement of distances when the eyes are situated in an aeroplane travelling at a high rate of speed. Some months ago I had to examine an air pilot who had been flying during the war and subsequently, and who had experienced no difficulty in his spatial judgements, although he only had monocular vision. He had a convergent concomitant squint, seeing 6/5 with the fixing eye and 6/36 with the squinting eye. He appeared to have perfect judgement for distances, and to be in every way fitted for the flying for which experience had already demonstrated his fitness. The only doubt in my mind lay in the fact that he had only one useful eye, and consequently no "spare part" in the event of an accident to the one good eye. The regulations would class him as unfit because lacking in binocular vision—not because lacking in a spare part.

Now when a person with binocular vision has one eye occluded, his spatial judgements, at any rate for near objects, are interfered with. This is not the case with the possessor of a perfectly alternating strabismus who is accustomed to using either eye with equal facility. Can one avoid the conclusion that the unattainable ideal in an aviator would be to have a perfectly alternating divergent strabismus, thus giving a wider field of view with a perfect spare part?

It is a question of a different sort when we come to the requirements of stereoscopic vision at very close range, such as ophthalmic surgery. At this range the accommodation effort should help largely—perhaps as much as the convergent effort—in forming a judgement. Eminent surgeons, as far as I know, are of the unanimous opinion that binocular vision is necessary for an ophthalmic surgeon. It would be interesting to learn whether this opinion is the result of experience with students and others who have for long been accustomed to monocular vision, and whether they consistently err unfavourably with those possessing binocular vision, and also whether other causes of clumsiness than the lack of binocular vision had been excluded. It would, of course, be necessary to exclude those who have binocular vision at ordinary range but weak convergence and fusion for near objects. Bishop Harman, in stating his experience with strabismic

not mention whether he had investigated the matter carefully or whether it was merely a general impression derived from his large experience.—I am, etc.,

Brisbane, March 14th.

E. O. MARKS.

### INSULIN AND DIABETES.

SIR,—In a letter which appeared in the *BRITISH MEDICAL JOURNAL* of November 18th, 1922 (p. 997), I ventured to predict that the optimistic forecasts then being circulated in the press as to the curative properties of insulin in diabetes would not be fulfilled, and that its true sphere of usefulness was likely to be limited. I have since had the opportunity of putting the treatment to a practical test in a number of cases of various types with insulin prepared in my own laboratory, and the results obtained have tended to confirm the conclusions I arrived at on theoretical grounds. From the articles which appeared in your issue of April 28th it would seem that the experience of other English workers has been similar to mine, for, although it is evident that insulin is capable of reducing the sugar content of the blood in all forms of hyperglycaemia, it is not a "cure" for diabetes in the popular sense of the term—that the patient is able to resume an unrestricted diet after a course of treatment. In the large majority of cases the beneficial effects of insulin are only temporary, ceasing when the injections are discontinued; in a small proportion a permanent improvement in metabolism appears to result, but in my experience these are cases in which the hyperglycaemia and glycosuria are dependent entirely, or almost entirely, upon a functional deficiency of the internal secretion of the pancreas.

As a means for tiding diabetics over crises which are frequently uncontrollable by other methods of treatment, or for ensuring a maintenance diet in severe cases where the power to metabolize carbohydrate is permanently lost, insulin is invaluable, but for the average patient treatment with insulin under present conditions is a will-o'-the-wisp, reliance upon which usually ends in disappointment.

I am interested to see that the observations carried out by Drs. Kellaway and Hughes have led them to the conclusion that insulin improves metabolism by a transformation of carbohydrate into some other complex, with economy of oxygen and liberation of excess of carbon dioxide, for my own experiments, conducted along entirely different lines, have suggested that when insulin is injected the diminished sugar content of the blood which results is associated with an increase in the hydrolysable carbohydrate and deposition of glycogen in the tissues.

It is suggested by Dr. Leyton in his paper that a differential diagnosis between pancreatic and hepatic disease may be made by estimating the sugar in the blood after an injection of insulin, a fall in the sugar indicating a pancreatic origin for the hyperglycaemia, while no distinct change will point to the liver being at fault. Seeing that insulin reduces the sugar content of the blood even in normal animals in proportion to the dose, it would be interesting to have a full account of a case in which "no distinct change" was produced in the blood sugar by a full injection, and the reasons for concluding that the hyperglycaemia was of hepatic origin.

It is unfortunate, in my opinion, that the Medical Research Council have seen fit to adopt a unit of measurement for insulin differing from that originally described by its inventors, as it will lead to endless confusion and call for very careful distinction between doses given on the English and Toronto bases.—I am, etc.,

London, W., April 30th.

P. J. CAMIDGE.

### TREATMENT OF PUERPERAL INFECTIONS.

SIR,—Dr. Dudley W. Boswell takes issue with me on my views regarding the above. He finds that I have departed from the teaching which he and I received in Edinburgh from Professor A. R. Simpson. Than my old chief there was no more up-to-date teacher of midwifery. But twenty years ago knowledge of infective processes was not so advanced as it is to-day, and I am sure that Simpson would have been the last to claim that his teaching on any subject was to be the final word for all time.

The case which Dr. Boswell quotes, where death followed removal of a putrid piece of placenta during the febrile period, absolutely supports my contention. According to his chart the patient suffered from sapraemia until the intra-uterine interference was carried out; after that from septicaemia and pyaemia, and finally died.

May I quote a similar case coming within my knowledge? Some seven years ago a patient was admitted to my ward with a high temperature, fetid vaginal discharge, and obviously very ill. She had had a premature labour seven days before. The cervix was patulous. Blood cultures were taken daily for the next six days and were negative. On the seventh day after admission I was tempted to explore the interior of the uterus with my finger and remove some debris. The temperature, as in Dr. Boswell's case, fell and remained normal for about twelve hours and then rose higher than before. Blood culture, taken twenty-four hours after the interference, was positive for streptococcus, and blood infection persisted till the time of her death four days later.

Dr. Boswell does not mention that he took blood cultures in his case, but evidently, from the way in which his chart is worded, he believes that after his interference a blood infection was present.

It is just such cases as his, and the one which I have quoted, which make me feel so strongly that the interior of the uterus should not be interfered with in the presence of fever.—I am, etc.,

Edinburgh, April 30th.

B. P. WATSON.

### VENOUS PULSATIONS AND VENOUS TRACINGS.

SIR,—The article by Dr. Harrington Sainsbury on venous pulsations and venous tracings, published in the *BRITISH MEDICAL JOURNAL* of April 14th, seems to me a valuable contribution to the subject. I am glad that he emphasizes the importance, frequently so little appreciated, of the sphincter action of the auricular fibres at the junction with the great veins when the auricle contracts.

In my thesis for the M.D. Paris in 1896 I wrote:

"Si les veines ne se trouvent pas protégées contre l'action de l'oreillette par une valvule, elles se trouvent cependant protégées par une action sphinctérienne très efficace, et, à mon avis, il n'est pas plus difficile de comprendre comment l'oreillette propulse son contenu dans le ventricule, que de comprendre comment une laktière, lorsqu'elle ferme la main, fait écouler le lait du pis de la vache."

In the *BRITISH MEDICAL JOURNAL* of April 13th, 1912, in an article on the genesis of the venous pulse, I maintained the same view, and also suggested that the wave  $\alpha$  was probably an inertia or shock wave, due to the sudden arrest of the venous blood stream by the contracting sphincter. In fact, the contracting sphincter not only arrests the flow, but nips the adjacent veins, and must throw back the contents of the diminished lumen, thus aiding incidentally the formation of the wave  $\alpha$ .

In a leaden water pipe the sudden closing of a water tap at the end evokes a thud, which gradually swells and finally bursts the tube behind the tap. Screw taps are now generally used to avoid this. Were the tube elastic it would make a wave  $\alpha$  an inertia, or shock, or ballistic wave, and the closed tap would negative any theory of its possible regurgitant origin.

Dr. Sainsbury seems to have difficulty in attributing the wave  $\alpha$  to the mere advent of blood. He writes:

"Behind the block, and proceeding backwards from it, the blood would gradually accumulate. Can we see here the development of any wave (justly so named) within the veins by the smooth afflux under the low pressures of health?"

I maintain that the veins producing the wave  $\alpha$  are not dilated merely by receiving a "smooth afflux" of blood. They have to dilate, as I wrote in 1912, "till the dilatation is sufficient to absorb the inertia of the venous column."

One cannot push a candle through a door panel, but it is possible to shoot it through. Motion is as important as material. An incompressible venous column, suddenly arrested at its head, would resist the arrest by dilating the side walls of the containing vessel near the point of arrest. The dilatation would not be by a smooth afflux, but by a light hammer blow near the sphincter, heaping the blood up locally, and sharply dilating the adjacent venous walls; thus starting the wave, which along the jugular is finally recorded as the wave  $\alpha$ .—I am, etc.,

Mentone, April 21st.

D. W. SAINWAYS.

### AURICULAR FLUTTER SIMULATING DEATH.

SIR,—In the *JOURNAL* of April 21st (p. 698) Sir James Mackenzie refers to two very important cases of restoration of the heart beat following upon intracardiac injections of adrenaline, this after cessation of heart beat and respiration for periods of four minutes and three and a half minutes

## Obituary.

SIR SHIRLEY MURPHY, K.B.E., F.R.C.S.,  
Formerly M.O.H. London.

We regret to announce the death of Sir Shirley Forster Murphy on April 27th, at the age of 74. He had been in failing health for some time, but the immediate cause of death was influenza and bronchitis.

Shirley Forster Murphy was born in 1848, educated at University College School and Guy's Hospital. After qualifying M.R.C.S. in 1870 he set about acquiring experience in various directions with a view to fitting himself for what he seems to have regarded from the first as his life's work. He was for some years resident medical officer at the London Fever Hospital and also worked for a time as an officer of the Metropolitan Asylums Board, thus acquiring clinical experience of infectious diseases which served him in good stead. He became Assistant Director at the Animal Vaccine Station and was always specially interested in any question relating to small-pox or vaccination. He was for some years Medical Officer of Health in St. Pancras, there gaining knowledge of housing problems and of sanitary conditions generally, of which he made such good use in later years.

For a time he acted as the first honorary Medical Officer of the Mansion House Council on the Dwellings of the Poor, and already in these early years he was asked to undertake special inquiries, for example, into the sanitary condition of Southend and into outbreaks of infectious disease by the Local Government Board, and he also took part in a housing inquiry for the Home Office. He was particularly interested from the outset in various branches of work in connexion with public health outside his ordinary official activities; for instance, he formed a close friendship with Mr. C. S. Loch, the secretary of the Charity Organization Society, and was especially familiar with the work of Miss Octavia Hill and with that of the Rev. Samuel Barnett at Whitechapel. He was, moreover, appointed lecturer on Hygiene and Public Health at St. Mary's Hospital.

Throughout his life he was intimately associated with the Society of Medical Officers of Health, of which he was one of the secretaries and in 1891-2 and again in 1904-5 the president. In his first presidential address to the Society he said the beneficial results which were then accruing, from the activities of medical officers of health, were such as to convince people that this was work which should be assisted and not hampered. It is interesting, in the light of this observation, to compare certain average rates for the first three and the last three years of the 22 years during which the author of the statement was County Medical Officer. The death rate from all causes declined from 20.1 to 14.6; the death rate from the principal epidemic diseases fell from 5.57 to 2.98; and the infant mortality from 152 to 113 per 1,000 births. It was always his aim to secure the co-operation of his colleagues the medical officers of health. As he said, in 1905, soon after he was for the second time made president of the Society, speaking of his London colleagues, "My association with them has always been a pleasure. I have received their assistance, their kindly criticisms, and at all times their good will." He often spoke, too, of the cordial sympathy and support he received from the medical department of the Local Government Board, from the Chief Inspector of the Home Office and from the Superintendent of Statistics at Somerset House.

Soon after he qualified, he became a member of the Epidemiological Society and from 1877 to 1889 acted as one of its secretaries. In his arduous duties in connexion with this Society and the Society of Medical Officers of Health, he always relied largely upon the assistance of Lady Murphy. One of his earliest papers for the Epidemiological Society was on "Sanitary administration of dairy farms," in 1888. When he became president in 1894 he delivered an address on the Study of Epidemiology, in which he first made reference to the remarkable "August depression" exhibited by the notifications of scarlet fever and diphtheria in London. The "notch" in the seasonal curve of these two diseases

specially observable when consideration was limited to the school ages, and this phenomenon led to special study of the question as to how far "school influence" was operative in promoting the spread of these diseases. In the session 1887-8 he read a paper on "Seasonal variations in age distribution and fatality," and followed this up in the session 1899-1900 by another paper on "Seasonal variations in the age distribution of deaths in certain diseases." One of his latest contributions was a paper on the "Variations in the age-incidence of mortality" read in March, 1897.

He served at one time or another on several departmental committees and, either as witness or member, in connexion with Royal Commissions. He managed to learn a great deal about the behaviour of epidemic diseases in all parts of the world, and, as his friend Sir Arthur Whitelegge once observed, it was always a wonder to those who knew him how he contrived to keep himself abreast of all the latest work at home and abroad. Sir Arthur Whitelegge added that he suspected that Lady Murphy acted as a worthy helpmate in this, as in all other respects. His name was well known to epidemiologists and public health workers all over the world and he was always at the disposal of any foreign visitors and ever ready to give them every help in his power.

He was elected a Fellow of the Royal College of Surgeons of England in 1899, and he became vice-president of the Royal Sanitary Institute and of the Royal Statistical Society; he was awarded the Jenner medal by the Royal Society of Medicine, and the Bisset Hawkins medal for distinguished service to the public health by the Royal College of Physicians. In association with Sir Thomas Stevenson he edited Stevenson and Murphy's *Treatise on Hygiene*.

His wide outlook and early training and experience in so many branches of public health and epidemiology were no doubt largely responsible for the fact that in 1889 the first London County Council appointed him as its Medical Officer of Health. In the early days of the Council the question of the clearance of insanitary areas, which had been brought prominently before the public at the time of the Housing Commission, of which the late King Edward VII was a member, occupied a great deal of his time. He obtained detailed personal knowledge of the insanitary areas in the County of London, and devoted a vast amount of work to the study of these areas in co-operation with the local medical officers of health with a view to effecting clearances; he gave evidence at the numerous housing inquiries which were held during the succeeding years by the Home Office or the Local Government Board. The question of London water supply was the subject of a Royal Commission of Inquiry, in the early nineties, and the London County Council, on Sir Shirley Murphy's advice, had surveys made of the rivers Thames and Lee and their tributaries, with a view to evidence as to pollution being placed before the Commission. He was always impressed with the fact that the death rate from water-borne diseases in London (which was supplied with river water) did not compare unfavourably with the corresponding death rate in Glasgow (which obtained a pure lake supply brought from a long distance); and it was partly due to his general attitude on the question that the policy ultimately adopted was that of improving the existing river supplies and not embarking upon the ambitious project of going to Wales. He was always, however, concerned to see that steps were taken to obviate danger from flood water, and that full consideration was given to perfecting the arrangements for storage and filtration.

He had to do with framing by-laws relating to dust and refuse removal, to offensive trades, and to cottages and seamen's lodging houses in London. The operation of by-laws relating to house and trade refuse brought about great amelioration as regards fly prevalence. It had been the subject of comment by visitors from America and Continental cities to London that there should be no flies in the curtilage of houses or within the town of London, except in the case of decomposing materials.

Prevalences of infectious diseases were also a subject of his consideration. The outbreak of diphtheria in 1899-1900

Hamburg in 1892 caused much apprehension in this country, and, as a matter of fact, four cases of undoubted Asiatic cholera actually occurred in London in the summer of the following year, but the disease did not spread. The small-pox of 1893 and 1901-2—more particularly the latter—smouldered to some extent among common lodging-house inmates, and this led to a scheme, for the early diagnosis of small-pox cases generally, being elaborated by Shirley Murphy, and ultimately to the appointment of a special medical expert for this purpose. The particulars with regard to all doubtful cases were circulated by Sir Shirley to his colleagues in the different parts of London and in immediately surrounding areas. A number of milk outbreaks of scarlet fever occurred during the years when Sir Shirley Murphy held office, and prompt stoppage of the infected supply of milk was always secured by him. In 1894 he prepared a memorandum on diphtheria prevalence in London which stimulated further research into this question.

The nature of some of the various special reports included in his annual reports may be illustrated by reference to a few of them. The First London Life Table was prepared on the basis of the Census figures of 1891-1900, and published in 1901. Numerous reports on the sanitary conditions of various London districts were made year by year. In 1894 he reported on Enteric Fever in relation to water supply, and on an outbreak of Scarlet Fever in Blackheath, also on the Disposal of House Refuse and on Disinfection; in 1895 on London By-laws generally; in 1896 on prevalences of Diphtheria; in 1897 on By-laws as to Houses let in Lodgings; in 1898 on the Preparation and Sale of Food, on Provision of Public Slaughterhouses, and on Mortality in relation to overcrowding; in 1901 on Experiments on Disinfection; in 1902 on Accommodation for Women in Common Lodging Houses; in 1904 on Watercress; in 1905 on the conduct of the businesses of fried fish sellers, fish curers, and marine store dealers; in 1906 on Inspection of Food by riparian authorities; in 1907 on Cerebro-spinal fever; in this and the two following years, on nuisance from flies and vermin; and in 1909 on an outbreak of Scarlet Fever and on Pulmonary Tuberculosis.

From 1904 onwards night censuses of homeless persons in London were taken every February; they were found of great use by the Local Government Board, and largely contributed to provision being made to prevent accumulation of poor persons on the Thames Embankment in the winter months.

In 1904 he was knighted. Soon after his retirement from the office of Medical Officer of Health for the County of London the war broke out, and he at once volunteered for military service. He was placed in charge of the sanitary service of the London area, and entered upon his work as Lieutenant-Colonel R.A.M.C.(T.F.) at the Horse Guards. In 1919 he was created K.B.E. in recognition of these services.

In recent years he served on the London Insurance Committee, and acted as representative of the Government at congresses in America, and as Deputy Chairman of the Trade Board for the Fur Trade in Great Britain. In 1920-21 he was Master of the Society of Apothecaries, with which he had long been associated. In 1921 he was nominated by the Ministry of Health as a manager of the Metropolitan Asylums Board.

He married, in 1880, Ellen, daughter of the late Henry S. King, and sister of Sir Henry Seymour King, K.C.I.E. The deepest sympathy will be felt for Lady Murphy and her two daughters.

W. H. HAMER.

Sir Shirley Murphy was long a member of the British Medical Association; he was secretary of the Section of Public Medicine of the Annual Meeting in Belfast in 1884, vice-president of the Section at the meeting at Leeds in 1889, and president of the Section of State Medicine in 1901, when the Association held its Annual Meeting at Cheltenham.

A largely attended memorial service was held at the Church of St. Martin-in-the-Fields on the morning of Tuesday, May 1st.

#### A. E. BROSTER, L.R.C.P., M.R.C.S.

We regret to record the death at Exmouth of Dr. A. E. Broster, who practised for many years in Wirksworth. Arthur Erdswick Broster was born in 1854 and received his medical education at University College Hospital Medical School. He was house-physician to University College Hospital and afterwards resident medical officer to the National Hospital for the Paralysed and Epileptic. He took the diplomas of L.R.C.P. Edin. and M.R.C.S. Eng. in 1877, and in that year served as surgeon to the Red Cross in the Russo-Turkish war. Soon afterwards he settled in Wirksworth, Derbyshire, where he was greatly esteemed both for his character and his medical attainments. He was medical officer of health for the town for over thirty years and was a J.P. for the county of Derbyshire.

We are indebted to Sir THOMAS BARLOW for the following short tribute: I knew A. E. Broster well, as a student, a resident, and as a fellow practitioner. He was a good all-round doctor—good from start to finish. I saw many of his patients from the Derbyshire dales with him. His statements about his cases were models—terse, accurate, complete, with no essential omitted. He was modest, but he knew his job, was resourceful, and he could hold his own. It was a privilege to meet him, to hear his North Country speech and note his quiet humour. He was very humane and the staunch friend of every one of his patients. May there never be a lack of doctors like him on the English countryside!

The death of Dr. REES MORGAN of Newport (Mon.) took place somewhat suddenly on April 11th, although he had been in ill health for two years. He was born in 1855 at Llandovery, Carmarthenshire, and was educated at Llandovery College, and afterwards at Edinburgh and Glasgow. He obtained the L.R.C.P. and S. Edin. in 1884. His first three years of practice were spent at Treherbert, whence he removed in 1887 to Llandilo. There he carried on a very successful practice for ten years, but was obliged to relinquish it owing to a bad breakdown in health. A trip to South Africa and a short residence there completely restored him, and on his return he resided for a time at Bexhill. In 1899 he went to Newport, where, by his painstaking and self-denying work, he gained the confidence of a large clientèle, which he retained until his retirement two years ago. During the war Dr. Morgan's labours were greatly increased owing to the depletion of the medical profession and undoubtedly his unremitting toil shortened his term of life. He leaves a widow, three daughters and two sons—one of whom, Dr. Glyn Morgan, succeeds him in the practice. He was a member of the British Medical Association and of the Newport Medical Society and generally attended local meetings of the profession, but took no part in public work. A COLLEAGUE (S. H.) writes: Dr. Morgan was a man of very quiet and unassuming disposition, simple in his tastes and habits; his ready reading of character and understanding of human nature, together with a broad sympathy, made him popular with a large circle of friends. He performed many unostentatious acts of charity to the needy. Among his professional brethren he was highly respected; he was straightforward and honest and was never known to do a mean or unkind act. He leaves behind him a record of work well done and a sweet memory in the minds of his numerous patients and friends.

Dr. GEORGE FRANCIS RHODES of Huddersfield died on April 15th, aged 64. He received his medical education at the University of Edinburgh and the London Hospital and graduated M.B., C.M. Edin. in 1887. He had served as ophthalmic assistant at Middlesex Hospital, clinical assistant at Royal London Ophthalmic Hospital and senior house-surgeon to the Huddersfield Infirmary. In 1893 he succeeded his father in the appointment of medical officer of the North District and public vaccinator of the Central District of the Huddersfield Union, and only recently resigned owing to ill health. Dr. Rhodes was a member of the Huddersfield Division of the British Medical

## SOCIETY OF APOTHECARIES OF LONDON.

The following candidates have passed in the subjects indicated:

**SURGERY.**—R. Caplan, L. A. Daly.  
**MEDICINE.**—W. E. Farnham, B. Hart, L. D. A. Hussey, W. J. Jameson.  
**FORENSIC MEDICINE.**—B. Hart, L. D. A. Hussey, W. J. Jameson, I. Lipman, S. Thompson.  
**MIDWIFERY.**—C. M. John, I. Lipman, M. McW. Lopez, H. MacLachlan, O. Simandres, S. Thompson, R. A. Walker.

The diploma of the Society has been granted to Messrs. L. A. Daly, L. D. A. Hussey, M. McW. Lopez, and R. A. Walker.

## Medical News.

THE dinner of the Medical Society of London to commemorate the one hundred and fiftieth anniversary of its foundation by Lettsom in 1773 will be held at the Hyde Park Hotel on May 15th. Lord Dawson of Penn, President of the Society, will be in the chair, and H.R.H. the Prince of Wales has signified his intention of being present. Arrangements have been made to seat 350 persons, and a large and representative gathering is expected.

As we announced lately, a feature of the celebration of the eight hundredth anniversary of the founding of St. Bartholomew's Hospital will be the revival after nearly one hundred years of the great City Fair of London, Bartholomew Fair. The fair originated in the permission given to Rahere by Henry I to hold a cloth fair to assist the erection and maintenance of the hospital he was building on the site where it now stands in Smithfield. The students of St. Bartholomew's Hospital to-day have selected the Tudor period as being the one which perhaps illustrates Bartholomew Fair at its zenith, and the revels, contests, and sports which characterized the fair at that period will be reproduced this year. The Lord Mayor of London, in conformity with ancient custom, will open the fair, and the old ceremonies connected with this civic event will be reproduced. It is thought that many would like to contribute goods to be sold at this revival of an old scene, and gifts will be welcomed; they should be addressed to the Matron, St. Bartholomew's Hospital, E.C.1, and marked "Bartholomew Fair."

SIR THOMAS BARLOW will preside at the annual meeting of the Royal Medical Benevolent Fund to be held at the Royal College of Physicians, Pall Mall East, S.W.1, on Monday next at 4 p.m. The chairman will be supported by Sir Humphry Rolleston, President of the Royal College of Physicians, Sir Anthony Bowlby, President of the Royal College of Surgeons, and Sir William Hale-White, President of the Royal Society of Medicine. Addresses will be given by the Archbishop of Canterbury and Lord Sumner.

Among the honorary degrees which Glasgow University proposes to confer at the graduation ceremony next month is the LL.D. upon Sir Walter Fletcher, M.D., F.R.S., Secretary of the Medical Research Council, and Dr. W. C. Lusk, Professor of Clinical Surgery in New York University.

We have received a copy of the first number of a new quarterly magazine entitled *Ambulance*, which is intended to be a link between people at home and abroad who are interested in such subjects as first aid, hygiene, and the national health. The first number contains several interesting short articles, including one on the origin of ambulance work, by Sir James Cantlie, and another on the use and abuse of tourniquets, by Dr. W. Salisbury Sharpe. The periodical is well printed and has an effective cover design. It is published at the College of Ambulance, 56, Queen Anne Street, W.1; the annual subscription is 2s. 6d., post free, and single copies cost 6d., post free 8d.

The next session of the Dental Board of the United Kingdom will be held on Wednesday, May 9th. At the opening of the business at 2 p.m. the Chairman, the Right Hon. Francis Dyke Acland, will deliver an address.

The forthcoming reprint of the *British Pharmacopoeia*, 1914, will contain a slip showing the corrections made in this sixth issue.

The sixth session of the Health Committee of the League of Nations was attended among others by the new member, Dr. Nocht of the Hamburg Institute of Tropical Diseases, Dr. Cummings, Surgeon-General of the United States Public Health Service, and Dr. Semyasho, Health Commissary of Soviet Russia. Nineteen countries were invited to take part in an exchange of sanitary staff—namely, Austria, Belgium, Canada, Czechoslovakia, Denmark, Finland, France, Great Britain, Greece, Hungary, Italy, Jugoslavia, Norway, Poland, Rumania, Russia, Spain, Sweden, and the United States.

PROFESSOR GEORGE R. MURRAY, D.L., M.D., has been appointed to represent the Victoria University of Manchester at the ceremonies connected with the centenary of the birth of Pasteur which will shortly be held in Paris and in Strasbourg.

H.R.H. PRINCESS MARY, VISCOUNTESS LASCELLES, has promised to present the prizes and certificates to the students of the London (Royal Free Hospital) School of Medicine for Women on Saturday, June 2nd. The school has scholarships of the annual value of £1,010, which in the next session will be awarded. Full particulars and forms of entry can be obtained from the Warden and Secretary of the school, 8, Hunter Street, Brunswick Square, W.C.

The annual meeting and dinner of the Metropolitan Police Surgeons' Association were held at the Holborn Restaurant on April 26th, with Dr. Kennedy, the retiring president, in the chair. Amongst the guests present were the Right Hon. W. C. Bridgeman, M.P., Home Secretary, Sir Charles A. Ballance, K.C.M.G., chief surgeon to the Metropolitan Police, Sir Bernard H. Spilsbury, Dr. Cassidy, physician to the Metropolitan Police, Dr. Sanders, M.O.H. for West Ham, and Mr. Forrester Clayton, alderman of the Middlesex County Council. An enjoyable musical programme was given after dinner by Mr. Herbert Cave, Miss Edythe Barnard, and Mr. Webb.

THE Aberdeen University Club, London, is holding its sixty-ninth half-yearly dinner at Gatti's Restaurant on Thursday, May 17th, when Professor J. Arthur Thomson will take the chair. The honorary secretary is Dr. W. A. Milligan, 11, Upper Brook Street, W.1.

A MEETING of the West Kent Medico-Chirurgical Society will be held at the Miller General Hospital, Greenwich, on Friday, May 11th, at 8.45 p.m. The President, Dr. W. H. Payne, will deliver his presidential address. A smoking concert will follow, to which lady guests are invited.

THE North-East London Post-Graduate College has arranged an intensive course at the Prince of Wales's General Hospital, beginning on June 11th and lasting fourteen days. It will include lectures and demonstrations on clinical methods and cases, and work in the wards and special departments.

THE annual dinner of the Federation of Medical and Allied Services will be held at the Langham Hotel, Portland Place, W.1, on Wednesday, May 23rd, at 7.15 p.m., with the President, Sir Berkeley Moynihan, Bt., K.C.M.G., in the chair.

THE St. Bartholomew's Old Students dinner will be held on Wednesday, June 6th, at 7.30 p.m., in the Merchant Taylors' Hall, Threadneedle Street, with Mr. H. J. Waring in the chair. The honorary secretary is Sir C. Gordon-Watson.

At a meeting of the Central Midwives Board for England and Wales on April 26th, Sir Francis Champneys presiding, two penal cases were heard, judgement being suspended for reports in three and six months. The principal business dealt with subsequently included the appointment of the Approvals Subcommittee and the reading of a letter from the Ministry of Health stating that the Minister approved for the purposes of the apportionment of contributions from local supervising authorities the balance of £5,280 lls. shown against the Board in the financial statement for the year 1922. The lists of lecturers and of institutions, homes, and midwives at which and under whom pupil midwives may be trained were submitted by the secretary, and approved for the year ending March 31st, 1924.

NORWOOD SANATORIUM for the treatment of inebriety and drug addiction has succeeded so well that its directorate has been compelled to seek elsewhere to found a second institution for the same purpose and to be run on similar lines. After much search a suitable mansion was discovered near Wickham Market in Suffolk. Rendlesham Hall, with its surrounding park of 270 acres, was bought, and on May 1st was opened as a home for patients suffering from inebriety or addicted to drugs. The resident medical officer is Dr. Walter Asten. On April 27th the Hall was inspected by a party of medical men and women and others interested in the subject. The mansion is magnificently situated in the midst of wooded country. Its own gardens are unusually beautiful. Every modern convenience necessary for the cure of the disease and the pleasure of the guests has been installed. Much credit should be given to Miss Dunn, the lady superintendent, for the very tasteful way in which the house has been furnished. Inquiries should be addressed to the resident medical officer, Rendlesham Hall, Woodbridge, Suffolk. At the conclusion of the visit Sir Sydney Russell-Wells, Sir Humphry Rolleston, Dr. Jane Walker, Sir Robert Armstrong-Jones, and others expressed their keen appreciation of the new institution and of the work of its directorate.

MESSRS. ADAM HILGER, LTD., have produced a modification of their optical sonometer and have applied to it the name Low-Hilger audiometer. It is a sensitive optical hymnograph designed to record the pressure variation caused by sound waves.

THE Lord Mayor will preside at the 113th annual festival of the City of London Truss Society, which will be held at the Great Eastern Hotel, Bishopsgate, on Tuesday next, May 8th, at 7 p.m. The Society is a useful institution, and the trusses it supplies are prescribed by the surgeons who give their services to it.

## Observations

ON

## THE AUSTRALIAN FAUNA AND MEDICAL SCIENCE.

BY

WM. COLIN MacKENZIE, M.D., F.R.C.S., F.R.S.E.

(From the Australian Institute of Anatomical Research, Melbourne.)

## INTRODUCTION: FUNCTIONAL ANATOMY.

SPEAKING generally, the medical graduate has little concern with that department of biology which we term "applied zoology," or better, "applied comparative anatomy." Yet for the study of causation, without which no true advance can be made or principles enunciated, an intimate knowledge of applied comparative anatomy is essential, since by its means the student is brought into contact with numberless experiments on the part of Nature which are calling for explanation—experiments which represent the functional struggles through which the human body has been evolved. As we admit an evolution of structure so must we admit an evolution of function. A recognition that structure is a response to function is all-essential to those engaged in the practice of medicine.

One physiological structure does not originate another—one physiological structure does not cause the atrophy of another—as Elliot Smith has stated.<sup>1</sup> Both are dominated by functional needs. The teaching of zoology needs complete reorganization; it should be dominated by the needs of those whom it really most concerns—the general medical practitioner.

## FUNCTIONAL STUDY IN AUSTRALIA.

In the Australian Commonwealth are to be found, still living in their natural state, members of the two oldest orders of mammals—namely, monotremes and marsupials, corresponding to life on this planet many millions of years ago. They are examples of living embryology. Through them man is enabled to explore his past.

In one order (Marsupialia) are to be found a carnivorous mammal with no caecum, one (koala) with a caecum 8 feet long, and one (wombat) with a vermiform appendage resembling our own. To study these mammals from the point of view not only of structure but function in relation to medical science the Australian Institute of Anatomical Research has been founded in Melbourne, and receives an annual subsidy from the Government of Victoria. The Government has also reserved at Healesville—a mountain town about forty miles from Melbourne—an area of nearly 600 acres, 80 of which have been converted into a great wire-netting cage. Here, for example, the platypus, echidna, and koala can be found living, though under observation, in their natural state. The psychology of an animal like the echidna, with its richly convoluted brain, is well worthy of study. Kinematographic records are being made to study, for example, the movements of the blue-tongued lizard, which has a small leafed cerebellum, and whose limbs are used for propulsion rather than for support, with those of the platypus, whose cerebellum is more mammalian in character and whose limbs are used for support as well as for propulsion. Unfortunately, these animals are becoming rapidly extinct, and at the request of those interested the Federal Government of Australia has recently placed an embargo on their exportation. The embargo and the Research Reservation at Healesville represent a recognition by both Federal and State Governments that this great biological field belongs primarily to the medical practitioner.

## DUCTLESS GLANDS: NORMAL OR TYPE STRUCTURE.

In defining abnormal or pathological structure in man a knowledge of the normal or physiological is essential—in other words, we need type specimens as a basis for comparison. As the members of the Australian fauna are, like man, classified amongst mammalia, and as alcohol and syphilis need no consideration, W. J. Owen, histologist to the Institute, and I have during the past ten years been engaged on a histological investigation of all the organs of both monotremes and marsupials, so as to obtain the normal types with which human preparations could be compared. All our preparations are now available to students of histology. As an example I may cite the parathyroids.

Both the British and American medical student is told that they are composed of "columns of cells," which description may mean anything. The description of fresh specimens of these in the platypus is as follows:

"The gland is definitely lobulated—the interlobular connective tissue containing the larger vessels and nerves. The ground substance of the gland consists of a fine connective tissue reticulum with an enormous number of capillary vessels embedded in which blood cells are easily demonstrated. This capillary network is characteristic of the parathyroid gland. The secreting or epithelial cuboidal cells may be isolated or grouped; but they do not form alveoli. Colloidal material is not present."

In connexion with the ductless glandular system of the Australian mammals is to be found not only every gland so far described in man, but also glands not so far found in man. Are these glands really present in us? If not, is their absence physiological or pathological? In the monotremes we have failed to define tonsillar tissue, and in these the vocal cords are not present as in man. The tonsils are defined in the marsupial, and would appear to be associated with the evolution of the vocal cords in mammals. In the great Australian iguana the spleen is an insignificant structure swung on the mesogaster. In the "lowest" mammal, the platypus, with an increased blood temperature and the evolution of a diaphragm, the great omentum has appeared, the spleen has enormously enlarged, and its two lobes spread out in the abdominal cavity. It is of little purpose to discuss the uses of the spleen till we have solved the functional impetus that has introduced this change. The adrenals in the platypus, and especially in the carnivorous thylacius, are relatively large organs. In the eucalyptus-leaf-eating koala and phalanger the opposite obtains. Frequently in the phalanger, and occasionally in the koala, the right adrenal may be absent. What is the cause of this disappearance? Is eucalyptus extract from the leaf taking the place of adrenal secretion? In atonic bowel conditions such as prolapse, or in disease of the adrenals, the use of eucalyptus oil would seem to be worthy of trial. Furthermore, the medullary portion of the gland in the phalanger, in contradistinction to that of man, is greater in amount than that of the cortex, and in the platypus there is neither cortical nor medullary differentiation.

The fact that the two glands corresponding to the normal thyroid in other marsupials resemble in the kangaroo and wallaby lymphoid structures will come as a surprise to most physiologists. An examination of a series of 120 fresh glands showed that it was not common to find colloidal vesicles in these structures. The structure is chiefly composed of lymphocytes, and the Institute has specimens showing a further stage of replacement in which fibrous tissue is present without lymphocytes—the whole forming an interesting study on the mode of disappearance of organs.

In these animals, to whom thyroid secretion would not appear to be an essential, we have failed to find any enlarged parathyroids. In fact, it is questionable whether they are present. If a dissection of the neck and thorax of the adult platypus be made we find (based on an examination of 80 animals) the following constant ductless glands. On each side of the commencement of the trachea is a small parathyroid. In the thorax on the right of the aortic arch is a somewhat oval body about 1 cm. long; it is present in both male and female, and is a tubular type of epithelial gland without a duct system. It was first demonstrated by W. J. Owen and myself in 1918. Owing to its close relation with the constant thymus gland we have termed the body the parathymus gland. About the origin of the great vessels from the heart is a reddish body 2 cm. long—thyroid gland—whilst spreading on the ventral surface of the pericardium is the thymus gland, often 0.5 cm. thick. This animal, like the feebly muscular Tasmanian devil, but unlike man and the strong and muscular wombat, retains a well developed thoracic thymus throughout its adult life. Surely this is the most important factor in connexion with the physiology of the thymus—its necessity to the adult platypus and Tasmanian devil, and its absence even in the pouched specimens of wombat.

In addition, the male platypus has a large pair of Cowper's glands, 2.25 cm. long, and also three other large pairs of glands not so far described in man. One of these is the crural or poison gland, the secretion of which is carried by a duct to each leg spur. Another is a vesicular gland placed in the shoulder region in both the male and female platypus. This is much larger in the male than the female, and may weigh 8 grams. Here we have been unable to demonstrate a duct

system. The third gland stretches across the back of the animal in both male and female. It is mainly salivary in character, but in addition well defined tubular ductless areas can be demonstrated. These two latter pairs of glands were described by Owen and myself in 1918. It may be truly stated that mammalian endocrinology is yet in its infancy.

#### The Genito-urinary System.

The prostate gland first makes its appearance in the marsupial. In this mammal it reaches its greatest develop-

ment, and here its function should be studied. It is not found in either the platypus or echidna (Monotremata). In the Australian phalanger (*Trichosurus*) it may be 8 cm. long, 5 cm. in greatest width, and nearly 4 cm. thick. Arthur Thomson's statement that only in man does the prostate completely surround the urethra is erroneous—in fact, in the marsupial the prostate gland as such cannot be dissected from the channel contained within it.<sup>2</sup> The prostate is composed of glands of the compound tubulo-alveolar type with numerous columnar-cell lined ducts. In the platypus or echidna (non-prostatic) the penile urethra is a sex and not a urinary channel. In the marsupial (prostatic) the urethra is both a sex and urinary channel. The seminal vesicles have not made their appearance at this stage of mammalian evolution, which is probably explained by the existence of a breeding season. During the breeding season in both monotremes the breast tissue is well developed in the male, but in spite of the absence of development of the

prostate there is no instance of mammary development in either the male platypus or echidna. In the adult platypus the testes are large, freely mobile, and intra-abdominal. In the marsupial they have escaped from the abdominal cavity, possibly to avoid dorsal fixation for a future erect position, which is already apparent in connexion with the pancreas and duodenum.

In the kangaroo, wombat, and koala, with well developed cremasters acting as stays over the inguinal region, the internal abdominal ring is patent, and a free communication exists from the peritoneal cavity to the tunica. In other words, the kangaroo, with comparatively lax abdominal contents and able to leap 27 feet, has a hernial sac, yet no instance of "hernia" has been recorded amongst macro-podidae. In the Tasmanian devil with a poorly developed cremaster, the internal ring is closed—Nature has cured the hernia. In the platypus a well defined pair of Cowper's glands are present, opening by a duct for each into the sex penile urethra. A pair of well developed Cowper's glands are also present in the marsupial. They are older structures than the prostate. The Cowperian secretion is poured into a sex urethra, the prostatic secretion into a urino-sex urethra.

Is the almost complete disappearance of Cowper's glands in man, compared with the marsupial, physiological or pathological? In addition to Cowper's glands two pairs of large glands are also met with in the marsupial in the urethral region. They resemble in structure the shoulder glands mentioned in connexion with platypus.

A study of the female system throws light on Nature's method of unification of the Müllerian ducts, and hence on abnormalities in the female genital system. In connexion with the ovary of the wombat, especially the right, a firm

distinctive body is noted externally, which on section is seen to be enclosed in a well defined fibrous capsule and presents the typical structure of a corpus luteum. This body has been found well defined at each extreme of pouch development of the embryo. There is no record of distinctive placental development in the wombat. In the Tasmanian devil there is a direct branch of the vagus into the broad ligament. What is the functional impetus that expels the embryo from the uterus within thirty days in such a powerful animal as the wombat,

and necessitates placental development with prolonged retention of the human embryo? The echidna, with its richly convoluted cerebral cortex, is born in the egg stage.

#### THE COLON, CAECUM, AND GREAT OMENTUM.

##### (a) The Two Primary Types of Colon.

The mammalian colon, from the platypus up to man, may be primarily considered under two types. In one, which is best demonstrated in the Tasmanian devil, we have the whole intestine from the pylorus onwards (157 cm. long) swung on a dorsal mesentery.

(Fig. 1.) Of this, 22 cm. is colon and the remainder small intestine, and at the junction of the two a well defined direct branch of the right vagus is present. The dorsal mesentery at its attachment measures 7 cm., and of this 5.5 cm. is mesocolon—that is, the peritoneal fold on which swings the colon—the remaining 1.5 cm. corresponding to the root of the mesentery, the fold on which swings the small intestine. There is no caecal development, no pyloric relationship of colon, no develop-

ment of colon on the mesentery. This is the "ileal"

intestinal tract of Metchnikoff and Lane.

In the other type, which is best demonstrated in the Australian koala, we have also the large intestine swung on its mesocolon, whose long "attachment" is traced along the dorsal abdominal wall. (Fig. 2.) In addition, however, this dorsal abdominal wall is brought into relation with mesocolic or primitive colon is brought into relation with the pyloric region of the stomach by a firm band—mesial fold—1.5 cm. long and 1 cm. broad, and there is a development of a new colon (on the right of the band), which measures 150 cm. long, and a caecum which may reach 240 cm., both swung with the small intestine on the mesentery.

Fig. 1.—Plan of gastro-intestine in Tasmanian devil.

Fig. 2.—Plan of gastro-intestine in Australian koala.

(b) *Caecal Varieties.*

From the great caecum of koala all grades of caecal development can be studied down to the appendage met with in echidna and wombat. Where we have "pyloric hitching" of colon so we have the attempt at caecal and colon development on the right. The vermiform appendage in wombat resembles that of man and the anthropoid apes, except that in some districts in Victoria it has evolved further towards complete disappearance than in man. Studies of these are interesting sidelights on the mode of disappearance of organs. The wombat is a root and vegetable eater, its diet resembling that of early man.

(c) *Origin of Great Omentum or Splenic Mesentery.*

In both the primary types of intestines the spleen is well developed and free, being swung on its own special fold or great omentum. These together with a complete diaphragm are mammalian characteristics. The development of great omentum (lesser sac) is primarily correlated to the relatively great splenic development seen in the "lowest" mammal (platypus) in which the right ventral process of the spleen may reach 15 cm. in length. This is in marked contrast to the insignificant spleen and absence of great omentum noted not only in the smaller lizards but in the giant iguana of Australia (Reptilia). Although in Australian mammals the lesser sac formed by the great omentum is well defined, together with Winslow's foramen, it has no connexion with the colon.

(d) *Dorsal Fixation: the Erect Posture.*

Compared with the intestinal mobility of koala the modifying factor to produce the arrangement seen in man has been

the erect posture with its call for dorsal fixation. Experiments in simplification of the right colon towards the more human type, as first seen in lemur monkeys, can be studied in rodents. This new right colon with its large and small caeca, appendices, coils, and loops, can be well designated "the experimental colon." There are two regions from which fixation of the colon begins—namely, at the pyloric relationship (mesial fold) and in the region of the spleen. In the latter region dorsal fixation of spleen and pancreas are the initial factors, since they are connected with the colon by a fold—the left lateral—of which the lienorenal fold in man is the remnant.

Fixation of the descending colon and sigmoid begins at the splenic region, all varieties of this being seen, and as a rule the sigmoid is not fixed dorsally, being swung on a portion of the old mesocolon. Fixation of the right, ascending, or mesenteric colon and its mesentery begins at the pyloric relationship and spreads downwards, and in man the fixation of the caecum is still incomplete.

The sequential grades of this can be studied in the lemur, platyrrhine and catarrhine monkeys, and anthropoids up to man. The fixation of the colon (part of the primitive colon with its mesocolon) between the pylorus and the spleen begins opposite the pylorus and extends to the left. This is the transverse colon of man. Fixation is effected partly by shortening of the mesocolon, but mainly by the attachment through physiological adhesions of the great omentum to the colon and mesocolon. This is the second function of the great omentum and the reason of its retention in higher

types. The best animals for the study of the grades of this are kangaroo, baboon, and anthropoid apes. The transverse colon and its mesocolon are not primary boundaries of the mammalian lesser sac. They become connected with it in a purely secondary way. Much of the anatomy of the lesser sac, including the diagrams, might be conveniently forgotten.

## HUMAN.

FIG. 3.—Plan of commissures in human brain. (Compare Figs. 4, 5, and 6.)

(e) *The Two Parts of the Human Colon.*

The human colon consists of two divisions only: (1) From the ileo-caecal region to the pyloric region, where we have a direct vagal connexion, is right, proximal, or mesenteric colon. This includes caecum and appendage, ascending colon, and hepatic flexure. It is the new or "experimental" colon. (2) From the pyloric region to the mid-sacrum in the pelvis is left, distal, or mesocolic colon. This is the old or primitive colon, and includes the portions known in man as transverse colon, splenic flexure, descending colon, iliac colon, and pelvic colon. The classification of diseases of the colon should have reference to affections of one or other division.

## THE MAMMALIAN BRAIN.

A medical student attempting to learn the human brain without a knowledge of the brain of lower mammals is comparable to an architect's apprentice who receives his first lesson at Westminster Abbey instead of at a cottage. In these days of psycho-analyses and hinterlands the brain student has to remember that for practical purposes brain structure is the register of brain function. Functions, both sensory as well as motor, have followed along simple sequential paths, which can be traced. Disease destroys these functions, sensory and motor, in the reverse order.

Re-education for recovery must follow the lines of the acquisition of function. Little importance is usually paid to the human hippocampus. Compared with that of the monotremes and marsupials it is almost a relic. What functional struggle has caused so much disappearance of this structure in higher mammals? How many students associate the fornix with hippocampal disappearance? In learning the corpus callosum, which is not present in the Australian mammals, how often do we reflect on the functional impetus that has called it into being? Why is it such an important structure in man and the ventral commissure so insignificant? The functional history of these three commissures—the callosum, fornix, and ventral—is correlated to the functional history of the cerebral hemispheres in man. (Fig. 3.)

If a transverse section be made through the brain of the Australian stump-tailed lizard (Reptilia) where the right and left portions are connected, we find that each can be regarded as a cylinder, the ventro-lateral wall of which is thickened to form the striatum or efferent ganglion. This is connected with its fellow of the opposite side by a well defined bundle—the

FIG. 4.—Section through brain of the Australian stump-tailed lizard.

striate or ventral commissure. The remainder of the cylinder is narrower and is connected mesially with the opposite side by the dorsal or hippocampal commissure. This portion is pallium, and the dorso-mesial portion of it is known as hippocampus. (Fig. 4.)

If a similar section be made through the brain of an Australian mammal the same plan prevails and the same commissures are present, although the ventral or striate is

much larger than the dorsal or hippocampal, and is the great connecting commissure between the two hemispheres. The striate body has increased in size, and additional cortical or projectional tissue has been added in response to functional needs, such as limb developments, into which processes from the ventral commissure are noted. A distinct process of this is traced dorsally above the hippocampus. (Fig. 5.)

FIG. 5.—Section through brain of platypus.

to join with its fellow of the opposite side to form the corpus callosum. If a similar section be made through the brain of a "higher" mammal such as the rabbit, we find a corpus callosum continuous with the ventral commissure present—the hippocampus and hippocampal or dorsal commissure are well defined, but the ventral or striate commissure has atrophied as in man. (Fig. 6.) It is now no longer the great brain commissure. The advent of the callosum in the rabbit is not associated with hippocampal atrophy. This atrophy when it occurs is

FIG. 6.—Section through brain of rabbit.

not mechanical, but functional. Elliot Smith's statement that "in all mammals possessing a corpus callosum the hippocampus persists in an unchanged state only so far as the splenium of the corpus callosum" is not borne out by an examination, whether histologic or macroscopic, of the rabbit's brain. I draw attention to this because the rabbit is the mammal most frequently used for structural demonstrations to medical students. The brain of the rabbit, like that of the platypus, is devoid of convolutions; on the other hand, the brain in the echidna is richly convoluted and might be almost described as a miniature human brain. Why is there no necessity to connect the richly convoluted cortex of one side with the other in the brain of the echidna, and a necessity in the poorly developed cortex of the rabbit? Studying correlations, in the rabbit we have placental development and retention of the embryo *in utero*, whilst the echidna is an egg-laying mammal.

The production of the next generation is more certain in the rabbit than in the monotreme. The statement of Bainbridge and Menzies, that "the cerebral hemispheres are relatively larger in man than in any of the lower mammals," is not borne out by a study of this monotreme.<sup>1</sup> In all the above sections the sensory afferent ganglion or thalamus has to be divided. The necessity for functional specialization, that has resulted in its almost complete division as seen in man, has not yet arisen. The two motor striates are older than the two sensory thalami. Amongst the marsupials the thalamus reaches its greatest development in the powerful muscular wombat. Relatively the corpora quadrigemina are better developed in the marsupial than in man, though in the monotremes the posterior pair are poorly developed, as was pointed out by Meckel and Sir Richard Owen. In spite of the richly convoluted brain of the echidna its cerebellum is more primitive than that of the marsupial or higher mammals.

Nearly a century ago there was published from St. Thomas's Hospital a small volume on the brain, clinical, pathological, and physiological, based on comparative anatomy. It was the work of Samuel Solly, the friend of Astley Cooper, Charles Bell, and Marshall Hall. Through them Hunter's influence is apparent in its pages. It stands as a model of what such a work should be, and is worthy of a reissue.

#### CONCLUSION.

In this paper I have endeavoured to draw attention to the importance of this great biologic field and to indicate a few of the problems on which work is being conducted at the Anatomical Research Institute in connexion with the Australian fauna.

The importance is not academic but practical, and the elucidation of the numberless problems presented in monotremes and marsupials—anatomical, physiological, and pathological—must affect every department of medical science. No mention has been made of the heart, stomach, eye, larynx, or muscular system, which should all be considered from the same standpoint. As the basis of orthopaedics is muscular, and dependent on the law of muscular function that "the particular functions of any muscle are the result of the evolutionary history of that muscle," it follows that a knowledge of comparative anatomy, both structural and functional, is essential for the orthopaedic surgeon. The treatment of poliomyelitis, the greatest factor in the production of human deformity, is the immediate one, and follows definite comparative lines.

Disease is an attack on function as well as on structure—perhaps more on function. The effect on function—for example, in disease of the central nervous system such as poliomyelitis—may be out of proportion to the actual attack on structure. A cell may be capable of performing numerous functions which are not necessarily all liable to attack, or in the same proportion. Disease of an organ, interfering with its functions, does not necessarily mean interference with all its functions, and any biological system that takes no account of the evolution of function is, so far as medical practice is concerned, only a shibboleth. The teaching of zoology should be dominated by the needs of those whom it really most concerns—the general medical practitioners.

Again, the question of tissue regeneration is one concerning which we at present know very little. When an abdominal wound is closed the union is a pathologic fibrous scar, not a true regeneration of muscle, skin, and fascia. Why have skin and muscle lost this power and the uterine mucosa retained it? The lower we descend in the animal scale the greater the power of regeneration, and this is greater in cold than in warm blooded animals. The Institute has specimens in marsupials of amputation stumps (after trapping) in which the line of union is not discernible. How important for an operating surgeon to obtain a more rapid and more complete union of divided tissue! "Cure" of a diseased joint is not necessarily followed by restoration of function—the ideal.

One cannot help feeling that round the question of ductless glands lies the possible solution not only of cell stability but of cell regeneration. The empiricism that at present surrounds much of our treatment of ductless gland affections is traceable largely to the methods by which we have obtained our present knowledge—namely, the results of disease, surgical interference, and experiments on animals, not only domesticated, but taken indiscriminately from different orders. The association of the four glands in the adult platypus—namely, thyroid, thymus, parathyroid, and parathyroid—is surely not without its significance, especially in the treatment of spastic affections of children, where thymus is particularly indicated. It is regretful to state that within a very short period, with increased settlement, many of our important mammals will have disappeared in spite of a rigid State protection. They vanish never to be recalled, and take their functional secrets with them.

## Observations

ON

## THE PATHOGENICITY AND TREATMENT OF FLAGELLATE DYSENTERY.

BY

HAROLD E. WHITTINGHAM, M.B., CH.B. GLASG.,  
D.P.H., D.T.M. LOND.,

WING COMMANDER, ROYAL AIR FORCE MEDICAL SERVICE.

For the past four years there has been a determined attempt on the part of the Ministry of Health to prevent or limit certain infectious diseases which have become a real and great danger to the community as a result of the demobilization of the services. The Public Health (Pneumonia, Malaria, Dysentery, etc.) Regulations, 1919, have made these and certain other diseases notifiable, and definite power to deal with such diseases has been given to medical officers of health.

It is with flagellate dysentery that these remarks are concerned. The definition of dysentery in Article I (1) F of the Regulations reads: "The expression 'dysentery' includes amoebic and bacillary dysentery." Other forms of dysentery such as flagellate, are not notifiable, and thus there is no attempt to safeguard the public against them.

A survey of the literature of the flagellate dysenteries leaves the mind of the reader in a turmoil as to their pathogenicity or otherwise. Few writers in the past have admitted that the presence of flagellates in the bowel is anything but a mere coincidence when found along with dysenteric symptoms. Other observers would credit only *Lambia intestinalis* with pathogenic effects on man and still leave *Trichomonas intestinalis* and *Chilomastix mesnili* in the "mere coincidence" group. The opinions of a few authorities on the pathogenicity of *Lambia intestinalis* may be quoted with advantage.

Hurst (1918)<sup>1</sup> states regarding "Sometimes, however, recurrent attacks of dysentery, with the passage of large quantities of mucus containing enormous numbers of flagellates, in such cases the organism is probably the cause of the symptoms. The diarrhoea, which may persist in cases of dysentery after treatment with emetine or antidyenteric serum, is probably sometimes due to additional infection with lamblia, which is not cured by these means."

In the Memoranda on Medical Diseases in the Tropical and Sub-tropical War Areas, 1919,<sup>2</sup> the opinion of the vast majority of workers at that date reads: "The only one which is possibly pathogenic is *Lambia (Giardia) intestinalis*, whose habitat is the small intestine, and which is said sometimes to induce a persistent and troublesome diarrhoea."

Manson (1921)<sup>3</sup> states: "Lambia infection is associated at times with a type of recurring diarrhoea accompanied with abdominal discomfort and the passage of bile-stained mucus. . . . Relapses of a periodic type tend to occur. . . . Symptoms are thought to be due to the mechanical action of the parasite. . . . Many kinds of treatment have been tried without success."

Wenyon remarks (1915)<sup>4</sup>: "In other cases there occur at intervals attacks of diarrhoea with the passage of mucus in which lamblia are to be found in enormous numbers, so much so that the whole microscopic field is packed with them. After recovery from such an attack the stools become normal again and only encysted forms are to be found. The occurrence of repeated attacks of this nature with a certain degree of abdominal uneasiness preceding the attacks and the passage of such extraordinary numbers of flagellates, especially in the mucus, leads one to suspect that *Lambia intestinalis* may produce sufficient to justify us in regarding it as a parasite of the small intestine as glands of the small intestine as

the pathogenicity of the intestine, yet no good evidence to prove in man is pathogenic, but that to show that most and probably all of them are harmless."

Phillips (1915)<sup>5</sup> observes that "the evidence brought forward that they [faecal flagellates] are pathogenic is not very conclusive, but in the case of *Lambia intestinalis* is more convincing." The same author quotes a large number of cases recorded by such observers as Darling, Mathis, Meyer, Fairise, and Jaunin. These observers record cases of lamblasis leading to ulceration and even to perforation of the gut. One case ended fatally after perforation (Fairise and Jaunin).

Except for this latter case, the general opinion, especially in the tropics, seems to be that *Lambia intestinalis* is a harmless parasite of the bowel, or of minor pathological significance.

During the past four years there has been exceptional opportunity of thoroughly overhauling men who have returned from overseas suffering from dysentery, diarrhoea, enteritis, general debility, and neurasthenia. The failure to

find any obvious reason for their unfitness led to a routine investigation of these cases. Eventually, in an endeavour to get to the bottom of all such cases, the following routine examination was adopted in the Central R.A.F. Laboratory, London:

1. Thorough clinical examination.
2. Blood culture and blood smears for parasites. Blood count and agglutination tests for indirect evidence of certain diseases, such as chronic protozoal infections, sepsis, tuberculosis, enterica, dysenterica, undulant fever, etc.
3. Wassermann reaction for syphilis.
4. Faeces examination for bacterial, protozoal, or helminthic infection.
5. Urine for albumin, blood, casts, and parasites.
6. Sputum, especially for tuberculosis.

The examination of blood films, faeces, and sputum was performed for ten consecutive days in all cases; if any part of the examination cast suspicion on the diagnosis further tests were carried out. It should be mentioned that the stools were examined as passed normally as well as after purgation with calomel and magnesium sulphate. The latter procedure ensured a good evacuation of the bowel and minimized the chance of missing parasites inhabiting the upper bowel. The whole stool was immediately sent to the laboratory, and special attention was paid to the toilet paper, because mucus was often found on this when not present in any other portion of the motion. In this manner 716 cases have been investigated, with the results shown in Table I.

TABLE I.

Organism.	Cases in which Present.	Percentage.	Cases of Pure Infection.	Percentage.
<i>Entamoeba histolytica</i> ...	68	10	32	5
<i>Entamoeba coli</i> ...	34	5	18	3
<i>Iodamoeba bütschlii</i> ...	30	4	12	2
<i>Endolimax nana</i> ...	6	1	2	0.3
<i>Lambia (Giardia) intestinalis</i> ...	57	8	22	3
<i>Trichomonas hominis</i> ...	8	1	4	0.5
<i>Chilomastix mesnili</i> ...	14	2	6	1
<i>Tricercomonas intestinalis</i> ...	8	1	3	0.4
Helminths ...	12	2	10	1
Bacillary infections ...	10	1	8	1
Total number of cases in which the above organisms were found in the faeces	183	25	—	—

Many of the cases showed a mixed infection of flagellates and other intestinal protozoa or helminths with other diseases, such as malaria, syphilis, and enterica. Out of 716 cases examined, one or more types of the above enumerated intestinal organisms were found in 183 instances (26 per cent.). In 117 of these only one type of organism was found. As is shown in Table I, no abnormality could be found in 35 of the cases beyond the presence of flagellates in the bowel. Thus a prolonged investigation regarding symptoms and treatment was made of 22 cases of pure lamblia infection, 4 of trichomonas, 6 of chilomastix, and 3 of tricercomonas.

## PATHOGENICITY.

The pathogenicity of an organism is best studied by macroscopic and microscopic examination of the organs forming its habitat, and especially of any lesions produced. Short of this, the only method applicable is to prepare careful laboratory and clinical evidence. In "flagellosis" the opportunity of obtaining material at operation is small; the same holds good for post-mortem material. The writer has been forced to draw his conclusions from evidence obtained during the life of the patients.

Preparatory to discussing the symptoms of flagellosis it is well to note the chief intestinal flagellates and their habitats. They are as follows (the authority is given in parentheses):

1. *Lambia* or *Giardia intestinalis*. Duodenum or small intestines. (Lamb, 1860.<sup>6</sup>)
2. *Trichomonas hominis*. Large intestine and ileum. (Wenyon, 1920.<sup>4</sup>)
3. *Chilomastix* or *Tetramitus mesnili*. Large intestine (Wenyon, 1920<sup>4</sup>); small intestine (Boeck, 1921<sup>7</sup>).
4. *Tricercomonas hominis*. Large intestine.
5. *Tricercomonas intestinalis*. Large intestine to caecum. (Da Fonseca, 1917.<sup>10</sup>)

The symptoms to which attention is drawn in flagellosis are: recurrent attacks of diarrhoea and colic, passage of mucus and perhaps blood (ulceration), thickening and tenderness of certain areas of the bowel, a blood picture showing slight leucocytosis accompanied by a distinct relative increase of the large lymphocytes with at times an eosinophilia and neurasthenia.

Dobell and O'Connor (1921)<sup>6</sup> state that "flagellates are found more often in persons with diarrhoea than in healthy persons for the simple reason that the stools of the healthy persons are seldom examined." A detailed examination over a period of several years of the faeces of healthy and unhealthy persons has convinced the writer that flagellates occur far more frequently in the bowel of the unhealthy than in the healthy; flagellates are not found in the faeces of more than 5 per cent. of apparently healthy persons. This means that flagellates are not normal inhabitants of the bowel.

It is agreed that the finding of an abnormal organism in the bowel of a neurasthenic person in no way proves its pathogenicity, but it is folly to explain away any abnormal symptoms that may develop in that person as nervous in origin; should an attack of diarrhoea supervene it is labelled as nervous and no attempt is made to discover the cause of the neurasthenia. As is well known, chronic infections are apt to cause a series of symptoms termed neurasthenia; should this occur a vicious circle may be set up.

No one can say that recurrent diarrhoea is a normal condition in man, nor are such flagellates as *Lambia intestinalis*, *Tricomonas hominis*, and *Chilomastix mesnili* normal inhabitants of the bowel. When a case of recurrent diarrhoea is subjected, as detailed above, to a careful examination for a possible cause of the malady and none is found, except the presence of some flagellate, there is at least a strong suspicion of its pathogenicity.

Most of the cases of flagellate infection recorded here had a history of recurrent diarrhoea. The stools passed by patients with a lamblia infection were often distinctive. The motions were pulsatious, pale, and had a peculiar mousy odour—quite unlike the diarrhoeic stool usually met with in Great Britain. During the past two summers, while investigating patients suffering from phlebotomus fever in Malta, some cases were noted where the premonitory symptoms of that fever were diarrhoea and colic. In practically all of these

some intestinal protozoon was found in the faeces, while in those which did not show these symptoms such a finding was exceptional. *Lambia intestinalis* was the protozoon most frequently found, then *Entamoeba histolytica*, and lastly *Trichomonas hominis* and *Tetramitus mesnili*. Of the total number of cases of phlebotomus fever roughly 20 per cent. showed these symptoms, associated with the presence of a protozoon in the gut. This percentage of cases of diarrhoea and colic closely coincides with that observed in phlebotomus fever by other workers.<sup>10, 11</sup>

This contention as to the pathogenicity of some flagellates is further strengthened by the frequent passage of mucus containing large numbers of flagellates. In some instances microscopic examination of this mucus showed the presence of large masses of epithelial cells amongst which were entangled numerous lamblia or other flagellates. At times some of the lamblia were seen attached by their sucking discs to these "intestinal" epithelial cells. Thus certain flagellates appear to exert a physical or chemical action on the intestinal mucosa. The effect may be simply an increased stimulation of the mucous glands, or a more intense action leading to epithelial desquamation or even actual ulceration of the mucosa, as is evidenced by the passage of blood mixed with the mucus. The latter condition was particularly noticed in two cases of trichomonas infection when the bloody mucus passed per rectum contained large numbers of these organisms; on palpation of the abdomen a distinct thickening of the bowel was felt in the region of the splenic flexure in both cases, and also in the sigmoid flexure of one.

Attempts have been made to ascertain the tissue invasion power of intestinal flagellates. Wenyon (1915<sup>4</sup> and 1920<sup>8</sup>) and others have made histological sections showing these flagellates filling the gland acini and invading the mucosa of the bowel. In one case at least this invasion seems to have occurred *ante mortem*. This power of invading the tissues is proved in the case of animals by the culture of a trichomonas from the blood stream of a gecko suffering from a trichomonas lesion of the intestine (Chatton, 1920).<sup>11</sup>

Wenyon (1920)<sup>8</sup> has reported the invasion of the mucosa of the whole extent of the large bowel and the lower portion of the small intestine by *Trichomonas intestinalis*. In the

present series of cases the occurrence of jaundice in a patient suffering from a pure trichomonas infection points to the possibility of a higher habitat in the intestine. No other cause for the jaundice could be found. The trichomonas disappeared under the routine treatment described below. After five weeks the case relapsed; the jaundice and trichomonas returned together. The condition disappeared after a further course of treatment, and up till now, three years since treatment, there has not been any return of the jaundice, nor on periodic examination have parasites been detected.

Many of the cases of pure intestinal flagellosis investigated showed a distinct relative and absolute increase of the large lymphocytes in the peripheral blood stream. The objection so often made to the fallacy of blood counts was checked as far as possible by the fact that the blood counts of all the cases of disease and the controls were collected by a constant method, with the same instruments and between 9 and 10 a.m. daily. A point of interest was the occurrence of a varying degree of eosinophilia (5 to 8 per cent.) in some of the cases most troubled with flagellates. The percentage of eosinophiles returned to normal with the disappearance of the flagellates from the stool. Careful examination of the patients for several weeks before, during, and after treatment failed to reveal the presence of any other cause for the eosinophilia. According to Gulland and Goodall (1914)<sup>12</sup> intestinal irritation produces an eosinophilia. The occurrence of eosinophilia in flagellate dysentery further supports the theory of intestinal irritation in that condition.

Finally, chronic irritation of the intestinal mucosa is liable to lead to neurasthenia. This irritation may be either of a physical or chemical nature, and akin to the action of intestinal nematodes. Consider for a moment the structure and function of the intestine and its relations to the central nervous system. There is a certain store of nervous energy which is more or less the common property of the whole nervous system. This store may be drawn upon by any of the spinal, cerebellar, or cerebral arcs. Stimuli and their appropriate responses passing along these arcs gradually use up the available nervous energy. In health, sleep comes to restore this lost energy. Normally a person should start the day with 100 per cent. of nerve energy. Imagine the physical irritation set up by millions of flagellates whipping away in the gut, and, in the case of *Lambia intestinalis*, often attached to the epithelial cells lining it, or the chemical irritation produced by the effete substances thrown off by these flagellates. By one or both of these means unconscious messages are sent along the sympathetic nerve tracts, and all night long there is a leakage of the nerve energy which should be reserved for the coming day. Depending on the degree of the physical or chemical stimuli set up, the patient may awake with only 75 or 50 per cent., or less, of the normal amount of nervous energy required for the work of the day. There is no feeling of refreshment. Work is started, and when only three-quarters or a half is done, definite signs are seen of loss of nervous energy and tone.

There is irritability and want of concentration, and any extra pressure of work causes confusion. The term "flat spin" is very appropriate whether the work is that of flying or otherwise. How often do the subjects of chronic dysentery or malaria show irritability, want of concentration, and a long train of so-called minor and unimportant symptoms. In fact the condition is glibly termed "neurasthenia." Much time is often wasted in trying to restore the nervous equilibrium, but nothing is done to cure the disease which has produced these symptoms. Work is gradually decreased in amount and quality. The whole nervous system loses tone. Vasomotor symptoms such as lassitude, flushings, syncopal attacks, giddiness, and irritability are marked.

Symptoms such as the above are serious enough on terra firma where any mental errors may be corrected by others, but their importance is increased considerably in the case of the air pilot. A little delay in the reaction time may mean a serious crash. The sooner the condition is diagnosed the more likelihood there is of a cure. The earliest manifestations of neurasthenia are readily made apparent by the elaborate modern physiological tests to which air pilots are subjected from time to time (Flack, 1920<sup>13</sup>). The diagnosis does not end here—the cause must be investigated, for unless efficient treatment is given a proper cure will never be attained. Enough has been said to show that any chronic disease is a great danger to health, and that the so-called non-pathogenic infection, flagellate dysentery, is really pathogenic.

## TREATMENT.

Many of the cases under treatment harboured more than one type of parasite in their bowel. The habitat of these various parasites has been shown to differ, therefore an attempt was made to devise some form of treatment that would suit all or most cases of chronic protozoal or helminthic infection of the gut. With this end in view the contents of the alimentary tract were reduced to a minimum by putting the patient in bed for three days and placing him on as light a diet as possible. Thus it was hoped that more or less complete absorption of the food given would occur. At the same time sodium bicarbonate was given thrice daily in 15-grain doses. This treatment was repeated for three days, the idea being to clear away any mucus coating the internal surface of the gut, for the flagellates have been proved to be frequently embedded in the gland acini of the intestine. The clearing of mucus from around the head of any helminths present was also attained in this manner. In order to clear the intestines further of their contents and thus allow the specific drugs to exercise their maximum effect on the parasites lodged in the wall of the gut, a 3-grain dose of calomel was given at bedtime on the third day, and 2 drachms of magnesium sulphate administered at 8 o'clock the following morning. When the bowels had moved thymol was given in three 30-grain doses. This was given in cachets (15 grains in each cachet was found to be a convenient amount to swallow), two cachets hourly for three consecutive hours—usually at 9, 10, and 11 a.m. At 12 noon a further dose of magnesium sulphate was given to clear the bowel of the excess of thymol and diminish the risk of thymol poisoning. No food or drink was allowed from bedtime the previous evening until the thymol treatment had been completed. When the bowels had operated actively after the second dose of salts, a cup of tea without milk and a piece of dry toast was given. At tea-time an ordinary plain tea was allowed and chicken diet for dinner. At bedtime that evening emetine bismuthous iodide powder (E.B.I.), 1 grain in a gelatin capsule, was given, the following evening E.B.I. 2 grains, and thereafter for ten consecutive days the dose was increased to 3 grains. Thus a total of 33 grains of E.B.I. was administered.

During the fortnight following the thymol treatment high lavage of the colon was performed on alternate mornings with a solution of quinine sulphate in water (10 to 20 grains of quinine to the pint). For this purpose a rubber catheter was inserted into the rectum for a distance of ten to twelve inches and the quinine solution ( $\frac{1}{2}$  to 2 pints) run in gently by gravitation. The patient lay on the left side during the administration, and on withdrawal of the catheter was requested to lie flat on his back for five minutes, thereafter on the right side for another five minutes. In this manner a good lavage of the colon was obtained. This lavage was found most valuable in clearing away lumps of mucus containing large numbers of free forms of trichomonas and chilomastix. (Such lumps of mucus are often held up by the folds of the large intestine.) The rapid removal of large numbers of free flagellates must materially aid their final eradication by reducing the number of proliferating organisms.

After this course of emetine bismuthous iodide the stools were examined daily for at least three weeks, a purge being given at least once a week, and if the findings were negative during that period the patient was encouraged to lead a normal life, alcohol not being forbidden. If there was no return of the intestinal parasites during the next three days the patient was discharged from hospital and put on a tonic pill containing iron, arsenic, strychnine, and cascara. Monthly examinations of the stool were done for three or four months after discharge from hospital.

In the case of relapses an interval of seven to ten days was allowed after the first course of E.B.I. before a second course of thymol and E.B.I. was administered. During the interval salol, 10 grains, was given thrice daily to act as an intestinal antiseptic. In a few cases of lamblia infection salol had a distinctly beneficial action.

Only in a few cases was a third course of treatment given, as it was found that those cases which did not respond to the above treatment were practically incurable. These cases were put on salol, 10 grains thrice daily for a fortnight every month, and given colon lavage twice weekly. This treatment was continued for three months, the patient meanwhile doing light duty.

The results of the above treatment have been very satisfactory. At least 50 per cent. of lamblia infections have been cleared up according to the standards laid down, all the trichomonas cases except one have recovered, and two of the chilomastix cases have relapsed. (See also Barlow, 1916.<sup>11</sup>) This strenuous treatment has given results very comparable to those of E.B.I. in *Entamoeba histolytica* infections. In this latter infection, under the systematic lines of treatment laid down by Dale,<sup>15</sup> Low,<sup>17</sup> and Dobell,<sup>5</sup> quite a number of chronic cystic carriers fail to clear up; the percentage of cures is certainly less than 75. Dobell and O'Connor (1921)<sup>5</sup> criticize the treatment of flagellate dysentery thus: "The appearance of flagellates or their cysts in the stools of infected persons is frequently very irregular. We have numerous records showing that the stools of infected persons may be 'negative,' on microscopic examination, for considerable periods of time; and this is true of persons undergoing no treatment whatsoever." This statement is admitted, but it applies with equal force to infection with *Entamoeba histolytica*.

During 1918, in conjunction with Major O. H. Gotch, late R.A.F. Medical Service, twelve cases of protozoal infection of the gut (*Entamoeba histolytica*, trichomonas, and lamblia) were treated with novarsenobillon ("914"). The drug was administered intravenously, and a series of four to six injections given in each case. The first dose was 0.45 gram, the second 0.6 gram, and the remaining doses 0.75 gram. In no case was there any improvement of the intestinal condition.

## CONCLUSIONS.

The object of this paper is to emphasize the following points:

1. Flagellate dysentery is a pathogenic condition which, if allowed to persist, will eventually undermine the health of the patient and cause neurasthenia.
2. Certain cases are simply "carriers," as are some cases of *Entamoeba histolytica* infection. This in no way proves their non-pathogenicity. Such "carriers" are a great source of danger, inasmuch as they may infect others, especially in a military service where they are likely to be drafted overseas.
3. Contrary to what is usually stated, flagellate dysentery may be cured in at least 50 per cent. of cases. Stress is laid upon the advisability of the combined treatment by purgation, thymol, emetine bismuthous iodide, and lavage of the colon.
4. All cases of recurrent diarrhoea or neurasthenia for which no cause can be found, and in whom flagellates can be detected in the stools, should have a course of treatment as outlined above.

## EFFECTS OF EXCESS OF CALCIUM ON THE SKELETON.

BY

V. KORENCHEVSKY, M.D.

(From the Department of Experimental Pathology, Lister Institute.)

In my previous communications (1921-22) I determined the influence of a normal diet (N diet) or a diet deficient in fat-soluble factor (-A diet) upon the composition and structure of the skeleton of rats. These diets contained 0.25 to 0.26 per cent. Ca (about 0.4 per cent. in air-dry diet). This amount of calcium was acknowledged to be sufficient but not excessive, being rather near to the border-line of the physiological requirements of the organism.

There is a form of rickets induced solely by a deficiency of calcium in the diet—"rickets from calcium starvation." This is completely cured by the addition of calcium salts to the diet. Other forms of rickets develop on diets containing a sufficient amount of calcium, and the ingestion of even excessive amounts of lime salts is not usually followed by a complete cure. In Orgler's (1911) opinion the increased introduction of calcium is useless, as the capacity to deposit calcium in the bones is lost during the active stage of the disease. Grosser (1920), however, found that considerable retention occurred in rickety children when the calcium was introduced subcutaneously in the form of a glycerophosphate.

The question is, to which of these two groups of rickets do the affections of the skeleton, obtained by me (1921-22) in rats by means of -A diet, belong? It is also an interesting question whether, and to what extent, it is possible to increase the calcium content of the skeleton of a normal animal kept on the normal (N) diet used by me by the ingestion of large quantities of calcium.

For the purpose of solving these questions I conducted seven experiments. They were conducted on 39 rats, belonging to seven litters. The technique of the experiments was, on the whole, similar to that used by me in my previous experiments. The rats were fed on the same basal diets: (1) normal (N), containing a liberal amount of fat-soluble factor; (2) deficient in this factor (-A). The different conditions introduced into the present experiments, and clearly seen from Table I, were as follows: (1) In diets N2, N3, -A2, -A3, the amount of calcium was increased by the addition of  $\text{CaCO}_3$ , and (2) the normal diet of some rats contained as the source of fat-soluble factor butter only, without any cod-liver oil (NB).

TABLE I.

Diet.	Percentage of Fat in Fresh Diet.	Amount of Calcium in Fresh Paste.	Amount of Calcium in Air-dry Diet.
NB	11 per cent. butter	Per cent. 0.26	Per cent. 0.4
N1	8 per cent. butter + 2 per cent. cod-liver oil	0.25	0.4
N2	Ditto	0.52	0.8
N3	Ditto	0.77	1.18
-A1	10 per cent. cottonseed oil (no fat-soluble factor)	0.26	0.4
-A2	Ditto	0.52	0.8
-A3	Ditto	0.77	1.18

In all of the above diets about 0.5-0.51 per cent. phosphorus was present in fresh paste and about 0.77 per cent. phosphorus in the air-dry diet. The amount of calcium in the different diets was determined by McCrudden's method, that of phosphorus by A. Neumann's method. Shipley, Park, McCollum, Simmonds, and Kinney (1922) consider the optimum calcium content in air-dry diet about 0.67 per cent.; in their opinion, about 0.4 per cent. phosphorus represents the minimal content on which optimal development can take place. For comparison with the figures of these authors, my figures in Table I, "in air-dry diet," should be used.

Details of the experiments are shown in Tables II to V. The average consumption of food per diem by the different litters of rats was as follows:

	NB.	N1.	N2.	N3.	-A1.	-A2.	-A3.
Litter 638 ...	STIM. 17	STIM. 17	STIM. 17.5	STIM. 20	STIM.	STIM.	STIM.
Litter 640 ...	—	24	18	—	—	—	—
Litters A, B, C ...	15	18	16	15	10	12	11
Litter 689 ...	—	—	—	—	—	—	6.7
Litter of rats 701-705 ...	—	—	—	—	11.5	13	14

In some cases it was observed that the average consumption was greater when the food contained a greater amount of calcium.

## Results of Chemical Investigation.

An examination of the figures in Tables II to VI shows the following:

TABLE II.

Changes in the skeleton of two litters (638 and 640) of rats kept on normal diets. Litters 638 and 640 aged at the beginning of diet 19 and 41 days respectively; final age, 101 and 110 days; duration of feeding, 61 days.

No. of Rat.	Diet.	In Dry Bone.	No. of Rat.	Diet.	In Dry Bone.

**Normal Diet NB, without Cod-liver Oil.**—As is seen from Table III, when butter alone was used as a fat-soluble factor in the diet, and when the calcium content in fresh diet reached about 0.26 per cent, the calcification of the skeleton did not differ from that in rats fed on the same diet but with cod-liver oil substituted for part of the butter ration. The result was the same even when the calcium content in the latter diet was doubled (N 2 diet, see Table III). That is to say, some samples of butter, even when bought in winter, may contain such an amount of the antirachitic principle that even the addition of cod-liver oil to the diet does not increase the calcification of the skeleton.

**Normal Diets, N 1, N 2, and N 3, with Cod-liver Oil** (Tables II and III).—In these normal diets, containing butter and cod-liver oil as sources of the fat-soluble factor, the increase to double (N 2) or treble the amount (N 3) resulted either in no increase whatever in the calcium content of the skeleton, or in the calcification of the latter being increased very slightly (within the limits of physiological fluctuations).

**Diets Deficient in the Fat-soluble Factor.**—Among all the rats fed on such diets there was not a single case where the increase of calcium from 0.4 per cent. (in air-dry diet) to 0.8 per cent. (-A 2 diet), and even to about 1.2 per cent. (-A 3 diet), could restore the calcium content of the skeleton to the normal.

A great increase of calcium in the skeleton, in connexion with its increased content in the diet, was observed only in one litter (A, Table IV); but even in this case, as compared with the corresponding normal rat 667 A, in rat 671 A (on -A 3 diet) the calcium content of the skeleton was 27 per cent. less in fresh bone and 16 per cent. in dry. I came across a similar decrease in the calcification of the skeleton of rats kept on -A diet in other experiments (Korenchovsky, 1922, 3, p. 83). In another rat (670 A) from the same litter A, the calcium deficiency in the skeleton as compared with the normal rat 666 A was still more marked, being 31 per cent. (fresh bone) and 21 per cent. (dry bone). Besides this, in connexion with litter A it is necessary to mention the following. This litter was obtained from a dealer, and not reared in the Lister Institute, as was usually the case in my experiments. The diet of the mother rat during lactation, and of the young until weaned, was deficient in calcium (kitchen refuse, bread). This would explain the low calcium content of the skeleton of rat 669 (Table IV) of this litter on -A diet, such as I have never observed in rats fed on a normal diet during lactation, and which occurs only when the mother's diet during lactation is deficient in calcium or fat-soluble factor (Korenchovsky, 1922, C). In that case it is quite comprehensible that the ingestion of larger quantities of calcium caused a more rapid increase in the calcium content of the skeleton to the level

observed in rats on -A diet. The special experiment conducted by me and described elsewhere (1922, C, pp. 105-108) shows this very clearly.

In the case of four rats (677, 678, 684, 685) of litters B and C (Table IV), with an increased amount of calcium in the diet -A 2 and -A 3, the fluctuations of the calcium content in the skeleton kept within limits frequently observed in different rats of the same litter. For instance, in rat 678 on -A 3—that is, with the greatest amount of calcium—the calcium content in the skeleton was lower than that of rats 676 and 677 of the same litter, fed on -A 1 and -A 2 diets respectively.

In litter of rats 701 to 705 (Table V) there was slight increase in the calcium content of the skeleton of rats kept on -A 2 and -A 3 diets as compared with that of rats kept on -A 1 diet. These rats were born from a rat kept during pregnancy and lactation on a diet rich in fat-soluble factor. Therefore, owing to a congenital store of fat-soluble factor in their bodies they continued to grow fairly well, notwithstanding -A diet during the experiment. On autopsy they were found to be fat, well nourished, and with no signs of any macroscopical lesions in the skeleton. It is possible to suggest that some amount of fat-soluble factor, stored in the body of these rats, had enabled them to assimilate a larger, although not normal, amount of calcium when fed on diets containing an excess of calcium.

In contrast to this experiment was a cross experiment with litter 689 (Table VI) in whom the storage of fat-soluble factor was reduced to a minimum by feeding their mother rat during lactation on diet deficient in this factor, although rich in calcium (-A 3 diet). Notwithstanding the presence of an excess of calcium in diet -A 3 the calcium content of the skeleton of litter 689 was strikingly decreased (about 50 per cent. in fresh bone and about 35 per cent. in dry bone, below normal).

These two experiments indicate that even in the case of abnormally lowered calcium assimilation in rats kept on diets deficient in fat-soluble factor the degree of this assimilation depends upon a more or less complete exhaustion of the fat-soluble factor in the organism. Apparently an excess of calcium in the diet could be followed by slightly increased, although far from normal, assimilation of calcium, if the fat-soluble factor is not completely exhausted in the organism.

#### Histological Results.

Histological structure of the skeleton of rats kept on N B, N 1, N 2, and N 3 diets was normal and similar in all cases. I have mentioned in my previous communications that the ribs of rats kept on N 1 diet sometimes show slight concave flexure of the costo-chondral junction. I have observed this same feature in the ribs of some rats kept on normal diets containing a double or treble amount of calcium. Rat 682 on NB diet, which contained the smallest amount of calcium and no cod-liver oil, showed the most classical picture of normal skeleton.

In the experiments with litters A, B, and C (Table IV) the structure of the skeleton of rats on -A 2 diet was similar to that of rats kept on -A 1 diet. I described this picture several times. In rats of the same litters, kept on -A 3 diet, the histological changes in the bones were less pronounced, but these changes always vary on -A diet. In any case, the double amount of calcium (corresponding to McCollum's optimum amount of calcium in rat's food) had no influence on the structure of the skeleton. In these experiments histological changes in the bones of litters A, B, and C were found to be typical of late rickets—that is, without increase of the proliferating cartilage with some osteoporosis. This type of late rickets, slight or very slight, was also found in rats 701 to 705 (Table V). In litter 689 (Table VI), kept on -A 3 diet, but with an exhausted store of fat-soluble factor, moderately severe rickets was found. In these rats proliferating cartilage was two to four times more than normally increased, calcium deposition in the zone of provisional calcification was deficient, and the bones were as well osteoporotic. Therefore, the results of histological investigation were completely analogous to those of the chemical analysis and showed the importance of the exhaustion of fat-soluble factor from the organism in the development of rickets.

On the basis of the results of the experiments described above I think it possible to draw the following conclusions:

1. Butter bought in winter may contain a considerable amount of the antirachitic principle.

2. When the amount of calcium in a normal diet containing 8 per cent. butter and 2 per cent. cod-liver oil was increased

two or three times the calcification of the skeleton was either not increased at all or only slightly.

3. The ingestion of even very large quantities of calcium did not cure the rachitic calcium impoverishment of the skeleton of rats on a diet deficient in the fat-soluble factor.

4. When the exhaustion of the fat-soluble factor in the body of rats is not complete, an excess of calcium in diets deficient in fat-soluble factor may in some cases slightly increase the amount of calcium in the skeleton, though never sufficient to make the calcification normal.

5. On the basis of the data of the chemical and histological examination, the skeletal affections in rats on —A diet must be classed in the group of rachitic affections, which develop even with an excess of calcium in the diet.

## INTUSSUSCEPTION SUPERVENING ON CONGENITAL STENOSIS OF THE ILEUM.

BY

W. TURNER WARWICK, M.A., M.B.CAMB.,  
F.R.C.S.ENG.,

ASSISTANT SURGEON TO MIDDLESEX HOSPITAL.

CASES of intussusception as the result of congenital constriction of the small intestine form a group often emphasized in textbooks, but records of such cases are comparatively infrequent. In a series of 400 cases of intussusception at the London Hospital, Perrin and Lindsay<sup>1</sup> found only two due to this cause. According to Leichtenstein<sup>2</sup> intussusception as a result of congenital stricture is uncommon, as the dilated hypertrophied proximal segment is not easily invaginated into the small empty distal portion. The following case, therefore, seems of sufficient interest to record. I am indebted to the late Mr. T. H. Kellock for permission to publish it.

A boy aged 11 years returned home from school on June 30th, 1922, complaining of pains in the abdomen. On the 1st of August he was brought to the hospital by his mother, who stated that he had been vomiting; the sickness and pain continued throughout the night; next day the vomiting ceased though the pain persisted, becoming more severe at night. His condition became progressively worse, vomiting recurred, and he was admitted to the Middlesex Hospital on July 3rd. He was a tall thin boy of poor muscular development; his face was pale, drawn, and anxious, the tongue dry and furred, the lips and teeth were crusted. The temperature was 97°, pulse 124, respirations 28. The abdomen was distended and tender, especially in the lower part, and showed no movement on respiration. In the centre of the lower part of the abdomen was an indefinite swelling dull to percussion. No note was made as to visible peristalsis.

### Operation (by Mr. Kellock).

A right paramedial incision, 4 inches long, was made below the level of the umbilicus. The peritoneum was injected, and the cavity contained much blood-stained fluid. The distended and engorged small intestine which presented was followed down until the cause of the obstruction was reached in the lower ileum. This proved to be an intussusception. The greater part of it was reduced, but a portion some 4 inches long was irreducible, and showed gangrenous patches. Resection of this part was performed, and, as the patient's condition was bad, anastomosis was effected by a Murphy's button. The abdomen was closed except for a small gauze drain.

On the evening of that day the temperature rose to 99.4°, the pulse and respiration rate being 140 and 28. His condition remained critical for some days. Removal of the gauze drain on the fifth day released a discharge with faecal odour. By the eighth day the general condition showed slight improvement, but a fistula, freely discharging intestinal contents, had developed. The Murphy's button was not recovered until the twenty-eighth day. The escape of intestinal contents slowly diminished and the surrounding skin, which had been reddened and excoriated, began to heal.

The patient was discharged to a convalescent home seven weeks after the operation, with the fistula practically closed. His general condition was very satisfactory. He is now completely recovered, has put on weight, and looks robust and well.

The grant of the Medical Research Council and the hospitality of the laboratories of the Lister Institute have enabled me to carry out this work, and to them my thanks are due. I wish also to express my sincere gratitude to Professor C. J. Martin for his continuous support in this investigation, and to Miss M. Carr for her assistance in chemical analyses.

### The Specimen.

Examination of the specimen removed showed a pure enteric intussusception. When the two outer coats were divided longitudinally it was found that the intussusception had commenced by the invagination of a portion which was the seat of a congenital stricture into the part below. The stricture was over 2 inches in length, and the lumen of the gut at its narrowest part was not more than an eighth of an inch in diameter. The wall of the gut at the stricture is not much thickened, the external diameter being about a quarter of an inch. A nodule about the size of a hazel nut, which was incorporated in the wall of the gut, appeared to be the most advanced point of the entering layer; it was an effusion of blood into the tissues, probably secondary to the intussusception.

The whole specimen showed the congestion and ulceration usual in cases of intussusception of some days' standing.

The different ways in which a marked congenital stricture of the ileum may affect the life and health of an individual are well shown in the notes on three specimens in the Middlesex Hospital museum. Bland-Sutton,<sup>3</sup> who applies the name "imperfiorate ileum" to such deformities, has illustrated two of the specimens in his article in the *American Journal of the Medical Sciences* and in his book on tumours. In the first

specimen, which shows the condition to which he gives the name "septate ileum," the lumen is interrupted 36 inches above the ileo-caecal valve by a perforated diaphragm which reduces the diameter of the channel to a quarter of an inch. Externally a slight constriction marks its site. This septum had caused no symptoms, and was found post mortem in a man, aged 62, who had died from myocarditis and emphysema. The second specimen shows complete interruption of the ileum in an infant; the patient was under the care of Sir John Bland-Sutton, who diagnosed the condition and operated; death occurred, as it almost

The specimen removed at operation. (From a drawing by Miss D. Clephan.) The outer and middle layers have been opened up to show the congenital stricture. The most advanced point, B, shows the peritoneal surface; this on C, ulcerated or gangrenous portion.

invariably does. Only two cases are recorded in which an infant with complete stenosis in this region has recovered. In both of these the lesion was single, and it was possible to perform entero-anastomosis. When the condition is multiple death has so far invariably been the result. In many cases, according to Clogg,<sup>4</sup> even where the lesion is single, the lumen beyond the occlusion is either blocked with inspissated mucus or so narrow that the passage of meconium along it is still prevented.

The third specimen, recorded by Leopold Hudson,<sup>5</sup> was obtained post mortem from a boy aged 8, who died of peritonitis; until twelve months previous to his death the boy had been perfectly healthy and free from abdominal trouble. The specimen shows a segment of gut situated 38 inches above the ileo-caecal valve, so narrow for a length of three-quarters of an inch that it barely admitted a probe. This stenosed segment connected a hypertrophied and distended proximal portion of small intestine with a distal part apparently normal. A small perforation had occurred just above the narrow segment, causing a fatal result. The autopsy revealed an intussusception considered of an invaginated nature, formed by the invagination of the upper loop into the lower for a distance of approximately 2 inches.

Sir Arthur Keith<sup>6</sup> collected and grouped specimens of congenital strictures and occlusions of the alimentary tract of congenital

or obscure origin found in the museums of the Royal College of Surgeons and various medical schools. The total number of specimens was 86: the jejunum or ileum was affected in 15 (those having an associated Meckel's diverticulum were not included). Sir John Bland-Sutton has found that these stenosing abnormalities of the ileum are associated with the obliteration of the stalk of the yolk sac, and are sometimes complicated by a persistent Meckel's diverticulum.

Keith also collected from the same museums a total of 95 cases of Meckel's diverticulum, in 27 of which marked constriction or narrowing was found in the neighbourhood of this abnormal structure. The constrictions were of two kinds—those due to pressure or traction of the mesentery of the diverticulum as it crossed the ileum, and those due to irregular growth or expansion of the Meckelian loop of the ileum, the last part of the ileum to be differentiated off from the yolk sac. Of the 95 preparations, intussusception was present in 3, but whether any of these were due to constriction, as distinct from the diverticulum, is not stated.

Meckel's diverticulum is said to be present in 2 per cent. of all individuals. Since the rarer specimens showing a secondary lesion are likely to have been preserved at the expense of the more common ones, it would appear that intussusception associated with Meckel's diverticulum is somewhat rare. In the collection of Perrin and Lindsay, enteric intussusceptions form less than 7 per cent. of the total, and Meckel's diverticulum is responsible for 5 of these.

Bland-Sutton has pointed out how often congenital constrictions are found where embryonic diverticula occur. In the duodenum the common congenital occlusion is caused by a septum just above the entry of the bile duct, and is probably associated with the outgrowth of the embryonic buds of the liver and pancreas. In this situation, therefore, it occurs at the junction of the two different morphological parts of the alimentary tract, the foregut and midgut. In the ileum, stricture occurs most commonly in close relation to the site of a Meckel's diverticulum. It is not easy to see how this explanation accounts for all the occlusions of the ileo-jejunal segment.

The following cases illustrate the varieties of deformity that may occur in that region:

Keith's series include 3 cases of multiple stenosis (in 2 the jejunum was affected, in 1 the ileum), 1 case of complete occlusion just above the ileo-caecal valve, and 1 case in which continuity was interrupted just at the valve. In the 6 other cases of jejunal stricture of his series the deformity varied from local narrowing to complete absence of a segment of gut and mesentery.

Rock Carling<sup>7</sup> records a case of stricture just below the duodeno-jejunal flexure. Morley<sup>8</sup> describes a case of occlusion at the ileo-caecal valve.

The theories advanced in explanation of the strictures have been admirably expounded by Clogg, but the more important points may be recalled.

### 1. Relation to Diverticula.

Meckel's diverticulum can, according to Leichtenstern, occur at varying points along the jejunum and ileum. He gives cases in which a single diverticulum has been found near the mid-point of the ileum, at the ileo-jejunal junction, and even in the jejunum. Crymble<sup>9</sup> records a case of persistent vitelline duct connected with the appendix. Lamb<sup>10</sup> records cases where diverticula were seen in the jejunum (14 cases) and in the duodenum (7 cases).

More recent authorities state, however, that many true diverticula in the upper part of the ileo-jejunal segment are associated with accessory pancreatic buds. The relation of these diverticula to stenoses and occlusions has not yet been worked out. It is possible that, as in the development of the normal pancreatic buds, conditions which permit the formation of septa may be present. However, I can find no reported cases of developmental septa or constrictions in relation to such diverticula.

### 2. Relation to Proliferation of Mucous Membrane.

Tandler,<sup>11</sup> who first pointed out that the duodenal lumen in the human embryo of 30 to 60 days is more or less completely obliterated by proliferated epithelium, suggests that a similar epithelial occlusion may exceptionally be found in all parts of the embryonic intestine. Keibel,<sup>12</sup> in an embryo of 11.5 mm., found that the epithelium of the lower part of the intestines blocked the lumen in two places, but did not observe similar conditions in other specimens.

Although occlusion by septa, and even narrowing of the gut, might be accounted for by the persistence of this

obliteration of the lumen, it is not easy to attribute absence of a segment or absence of the mesentery to this cause. The narrowing which occurs in the duodenum when a septum is present merely indicates that development has stopped at an early period, without explaining the cause.

### 3. Failure in Evolution of the Intestinal Tract.

The jejunum, ileum, and proximal part of the colon are all developed from that portion of the midgut which overlies the yolk sac in embryos up to the end of the third week. It is possible, therefore, that strictures are brought about by irregular closing of this portion, but if such irregularities occurred, congenital dilatation of this segment might be expected to exist more commonly. It seems more likely that strictures arise during the subsequent elongation of the midgut and hindgut. Certainly irregularities occur in this process.

In Abernethy's case of a boy aged 12 the small bowel was only 2 feet in length, while the colon measured 4 feet.

Sir Alexander MacCormick<sup>13</sup> reports a still more remarkable case of a well developed man of 28 who had always had good health except for periodic attacks of vomiting. At an exploratory operation the stomach was found to fill the entire abdominal cavity, and to reach down to the pelvis. The small intestine was represented by a short segment 6 inches long, reaching from the duodeno-jejunal flexure to a caecum situated in the left hypochondriac region. No appendix was found, and a modified colon followed the course of the portion of the normal large intestine distal to the splenic flexure.

Failure in development of a small segment would give all varieties of stricture from mere narrowing to complete absence of a portion of gut with its mesentery. Certain factors have to be considered in relation to this lack of development.

(a) *Vascular Anomalies.*—Arrest of growth of the intestines, according to Jaboulay, depends upon vascular lesions—for example, embolism and thrombosis of the mesenteric vessels. It is easy to see that such lesions would cause such abnormalities, but proof of the statement is difficult. The same effect might be produced by congenital vascular defects, by dragging on the vessels by adhesions, or by pressure of tumours upon them. Davis and Poynter<sup>14</sup> found small lumina and sclerosis in the arteries of the segments affected in a case of multiple atresia of the jejunum.

(b) *Peritonitis* has been widely accepted as a cause of congenital stricture. Tubercle and syphilis provide the majority of such cases, but other forms are said to exist. The focal effect necessary for the production of single stenosis (the 'commonest type') is unusual in any such infection of the peritoneum.

### 4. Mechanical Causes.

(a) *Blocking of the lumen* by means of mucous plugs has been described as a cause of intestinal obstruction in infants, sometimes in relation to narrowing of the lumen, sometimes with a normal lumen. Its occurrence is rare, and the condition has little or no claim to consideration as a general cause of stricture.

(b) *Adhesions* formed in development or as a result of peritonitis are said to cause congenital strictures, either by compression of the gut by bands or by dragging on the vessels of the mesentery. They may also initiate a volvulus.

(c) *Volvulus* is believed to account for some cases. Morley attributes his own case to this cause, and suggests that it may explain Waterston's<sup>15</sup> case also.

It must be remembered that the intestines undergo a complete counter-clockwise turn in passing from the foetal to the adult position. The stalk of the vitelline duct has usually disappeared before rotation commences. If, however, involution of the duct fails, so that attachment to the umbilicus persists, the possibility of a clockwise strain at the point of attachment of Meckel's diverticulum must be borne in mind. A specimen of a Meckel's diverticulum retaining its umbilical attachment is illustrated by Evans.<sup>16</sup> The same possibility is present whenever a peritoneal band attaches the foetal gut to the anterior abdominal wall at an early stage. The question arises as to whether a case of multiple congenital stricture may have arisen from multiple volvuli.

Volvulus, when present, is usually clockwise, but many turns are present. It may be that it is a continuation of the process started as above, but there is no proof of such an origin. It may equally well have arisen in a more haphazard way at an early stage, or the volvulus may be a secondary factor in a gut already the subject of atresia.

The theory that congenital constrictions arise from torsion might account for those cases in which there is irregularity

or absence of the mesentery; it does not, however, account for those specimens which show mere narrowing, but no suggestion of torsion, and no disturbance of an orderly vascular arrangement. It can only play an occasional part in the formation of intestinal abnormalities.

(d) *Intussusception* was undoubtedly present in the constricted portions found in the cases examined by Braun and Chiari,<sup>16</sup> but again the normal anatomical arrangement of the vessels present in many cases of simple narrowing is against this as a universal cause.

In considering the recorded cases of congenital stricture of the ileo-jejunal segment two points are striking: First, that the segment may be affected in any part of its length by single or multiple constrictions, which, when considered as gross anatomical lesions, resemble one another closely, and in their difference in degree tend to form definite steps in a series. Secondly, that these apparently similar conditions have been credited with widely divergent origins.

The causes given above in the mechanical group do not apparently occur sufficiently often to disprove the possibility of their being associated lesions—secondary developments in portions of gut already malformed. It is difficult, therefore, to avoid the conclusion that there is some common primary etiological cause underlying all these lesions.

The two factors that would appear to account for the majority of these cases are: deficient evolution of the intestinal tract and excessive involution of the vitelline duct, but the details of the processes underlying these departures from the normal are at present little understood.

## OPTIC ATROPHY.\*

BY

R. E. WRIGHT, M.D., B.Ch., MAJOR I.M.S.,

SUPERINTENDENT, GOVERNMENT OPHTHALMIC HOSPITAL, MADRAS.

"OPTIC ATROPHY" is a term applied to a pale condition of the disc when some or all of the fibres of the visual path as they pass through the foramen sclera are degenerated. Pallor does not always mean atrophy, but when associated with a permanent defect in the visual field it probably represents atrophy. The cause of pallor is not always very obvious; in some instances it is determined by emptiness of capillaries at the disc; in the grey pallor of tabes it is difficult to say what the coloration is due to; in post-papillitic pallor the fibrous tissue elements decide the whiteness.

In a degeneration of the nerve such as is met with in tabes or disseminated sclerosis there is a wasting of the nerve elements due to constriction by the proliferation of the supporting structures with the minimum of inflammatory change. In this type of case the neurone is affected in the course of its axis-cylinder process. Should the neurone be affected at the cell level—that is, in the retina—the axis cylinder undergoes degeneration, which may produce a very similar picture as, for instance, in alcohol-tobacco combined poisoning.

A direct compression of the neurone between the disc and the lower visual centres (for example, pituitary enlargement) gives rise to a simple degeneration which takes place fairly rapidly towards the retina as well as towards the brain. A different picture results from a stasis at the nerve head, produced by pressure of cerebro-spinal fluid, such as occurs in brain tumour. Here there is much swelling of the supporting tissues; the pressure affects the neurone, but not for some time, and, although inflammatory products are not in evidence, the subsidence is attended by proliferative changes of the glial and endothelial elements; formation of fibrous tissue and compression of the nerve elements ensue. In neuritis the fluid in the subarachnoid space round the nerve may not be under increased pressure, but there may be an inflammatory condition of the meninges clothing the nerve and of the pial

septa with vasculitis and cellular changes. Here the subsequent proliferation is marked and perivascular proliferation leads subsequently to marked contraction of the vessels. Even in a simple occlusion of the central artery, where the neurone suffers from sudden deprivation of nutrition and death at the level of the retina, there is a perivascular proliferative change at the disc productive of fibrous tissue. The amount and distribution of the fibrous tissue give a clue to the cause of the atrophy, and the appearance of an atrophic disc is determined by the relative changes which take place in nerve element, interstitial tissue, and vessels respectively. It may be an advantage to think of the general causation under three heads:

1. Initial damage to the neurone itself (parenchymatous).
2. Initial damage to the supporting tissues, with or without oedema or inflammatory exudate, followed by secondary damage to the neurone (interstitial).
3. Initial interference with the blood supply with secondary damage to the neurone (vascular).

Of all the causes of atrophy, congested disc is chief. It is of two main distinct types (different in method of production but very similar in ophthalmoscopic appearance), frequently referred to as papillitis and papilloedema. Both are associated with redness and swelling; but the one is active, the other passive. If a localized inflammation takes place sufficiently far back along the nerve the disc may not show any change, but this is not very common. With these points in mind, I show a rough tabular grouping of different types of optic atrophy, giving in brackets some of the common terms used in the books to designate different types. There is, of course, much overlapping in such a grouping and it cannot be regarded as accurate, but from a clinical point of view it may be thought useful.

## Types of Optic Atrophy.

1. Optic atrophy following direct damage to neurone by pressure or selective poisons, including subinflammatory increase in interstitial elements, excluding inflammation and oedema.
  - At the level of the retina: Methyl alcohol, alcohol, and tobacco; diabetes. (Axial atrophy; partial atrophy.)
  - At the level of the papilla and pars arteria centralis: Glaucoma; tabes, insular sclerosis. (Simple atrophy; spinal atrophy; primary atrophy; genuine atrophy; tabetic atrophy; grey atrophy; non-inflammatory atrophy.)
  - At the level of the orbito-cranial portion of nerve and tract: Pituitary diseases; insular sclerosis; tabes; fracture; hydrocephalus; carotid pressure. (Simple atrophy; secondary atrophy; descending atrophy.)
2. Optic atrophy following damage to neurone through post-inflammatory or post-oedematous change in supporting tissues.
  - At the level of the retina: Retinitis pigmentosa; retinitis (syphilitic) and choroiditis (renal). (Consecutive atrophy; ascending atrophy.)
  - At the level of the papilla and pars arteria centralis: Syphilis; renal disease; brain tumour; oxycephaly, etc. (Post-neuritic atrophy; post-papillitic atrophy; secondary atrophy.)
  - At the level of the orbito-cranial portion of nerve and tract: Acute true retrobulbar neuritis; periorbititis; orbital cellulitis and abscess; nasal sinusitis; influenza; encephalitis; acute infective diseases. (Secondary atrophy.)
3. Optic atrophy following damage to neurone and supporting tissues by deprivation of blood supply.
  - At the level of the retina: Arterio-sclerosis (with and without high blood pressure; embolism of central artery; quiniae. (Retinitic atrophy.)
  - At the level of the papilla and pars arteria centralis: Retrobulbar growth (?); haemorrhage into sheath; disease of central vessels (?).
  - At the level of the orbito-cranial portion of nerve and tract: Vascular disease.

The commonest variety of optic atrophy which we meet with in India is the post-neuritic atrophy of syphilis. Although a post-neuritic atrophy apart from the papil oedema and papillitis of cerebral tumour or meningitic disease may not be thought very common, in Madras there is no doubt that our most frequent atrophy is one which follows a mild insidious bilateral neuritis, which in no way resembles a papilloedema, inasmuch as all that can be seen during the neuritic stage is an almost flat dull-red disc with perivascular disc changes. Colonel Kirkpatrick laid stress on this variety during the period of his superintendency. In 284 cases of optic nerve diseases collected between 1914 and 1918, of which he took careful notes, syphilitic neuritis preceded this atrophy in by far the greatest number of cases. Of 58 cases of optic atrophy admitted to the wards in 1919 he states the bulk was syphilitic. The mildness of the neuritis and its insidious progress to a post-neuritic atrophy with a white

\* Abstract of an address delivered to the Madras Branch of the British Medical Association on February 5th, 1923.

disc, narrowed vessels, and an ill defined edge, induce one to think that the process is a localized perivasculitis of the nerve in the region of the papilla. The large vessels at first are normal; then the nasal arteries show white sheathing and narrowing, as also do the veins, until blindness eventually sets in with complete atrophy. There is no evidence of serous meningitis or cerebral symptoms. The fields usually show a generalized contraction for form and colours. It is very important to recognize these cases in the beginning, as they respond fairly well to mercury in the early stages. It is our custom to avoid arsenical preparations. I have on several occasions seen much harm done by the injudicious administration of large quantities of novarsenobillon and similar products.

In the atrophy of glaucoma one may get a pallor of the disc which I have often seen mistaken for simple atrophy. There are some cases in which a diagnosis is not at first clear. It may be a partial simple atrophy with the slightest cupping of the disc associated with giddiness, pain in the head, and other symptoms pointing to cerebral trouble. A careful perimetric investigation ought to disclose the true nature of such a case. The enlargement of the blind spot, as determined with the Elliot scotometer, and the nature of the contraction of the field will dispose of such conditions as are likely to give rise to bilateral simple atrophy. In addition, the peculiar features of glaucoma, such as intermittent increase of tension, help in making a diagnosis.

We must distinguish between ordinary renal disease and albuminuria arising during pregnancy. Ordinary renal disease, and in particular chronic interstitial nephritis, gives some of the most striking examples of papilloedema. As a rule the papilloedema is associated with retinitis, but there are certain cases in which this is not so, and here it becomes a matter of considerable difficulty to diagnose the condition from the papilloedema of brain tumour because certain of the pressure symptoms are very similar. We do not very often see optic atrophy which is the result of such nephritic cases because these patients commonly die not long after the establishment of the condition. This is not so, however, with the type of cases met with in connexion with pregnancy. Here one sees numerous cases of papillitis which apparently settle down altogether after the termination of the pregnancy. There seems to be much confusion about the signs and symptoms associated with the toxæmias of pregnancy, and the eye condition does not help in elucidating the mystery. All one can say is that from time to time, not very commonly, one sees post-papillitic atrophy, either partial or complete, with a history of onset associated with pregnancy, parturition, or the puerperium.

To the chemist and pharmacologist perhaps the most interesting group of atrophies is that associated with toxic neuritis (commonly called retrobulbar), in which the damage is directly to the neurone itself. A large group of substances is known to give rise to the disease called "toxic amblyopia," which is frequently associated with temporal pallor of the disc and true atrophy. It is unnecessary to quote the list at length: methyl alcohol, tobacco, ethyl alcohol, quinine, lead, carbon bisulphide, light arsenates are all included.

Last year we had a case in which a man had a "swig" of methylated spirit and was blind the next morning. By the time we saw him, some weeks later, there was complete optic atrophy. It would have been very difficult to tell from the appearance of the disc what the type of atrophy was; it might readily have been mistaken for the white disc and thread-like vessels of an old case of post-neuritic atrophy.

Quinine, although used in such enormous quantities in India, is in our experience rarely productive of atrophy. The effects of quinine on the eye seem to depend more on idiosyncrasy than dosage (provided the dosage is within medicinal limits). Some time ago, when the arylarsenates were more used, definite damage was done to the optic nerves. Fortunately tobacco does not as a rule produce atrophy; the vision usually returns to normal when the poison is cut off.

I turn now to some atrophies, both simple and post-papillitic, of surgical interest. The characteristic atrophy of pituitary enlargement or tumour in the neighbourhood of the pituitary body is of a simple, so-called secondary descending type. It is as a rule partial, and irregularly developed on either side; the characteristic feature in many cases is the peculiar field; there are no signs of brain tumour—that is to say, the ordinary pressure symptoms and papilloedema are absent. The appearance of the disc together with the peculiar field and x-ray investigation generally establish the diagnosis.

Most brain tumours produce an atrophy subsequent to papilloedema. It is sometimes very difficult to differentiate between the papilloedema of brain tumour, renal disease, and serous meningitis, such as might, for instance, occur in syphilis. Another rare but interesting type of case from a surgical point of view which is frequently associated with an optic atrophy of a post-papilloedematous type is oxycephaly.

From the point of view of public health I will briefly refer to a type of atrophy that we sometimes observe but know very little about. It appears in certain schools and similar institutions; the sequence of events is as follows:

The young patient is sent to the hospital for glasses because the vision is poor. We find that there is a definite drop in the visual acuity which is not accounted for by the condition of the discs. We also observe mild neuritis. As a rule the condition improves with food, tonics, and cod-liver oil. Associated with the condition very frequently is angular stomatitis. Certain cases of this group go on to a partial optic atrophy with general contraction of the fields. We have not been able to detect central scotoma, although at first sight one would expect to find central scotoma if the cases fall into the group of toxic amblyopias. It may be that the condition is purely one of nutritional disturbance.

Unsuitable and insufficient food with secondary alimentary disturbance is, I cannot help thinking, the big factor in many of our common pathogenic states—vascular degeneration, early senility, cataract, diabetes, etc.

A very interesting group of cases which form a potential source of optic atrophy is that associated with diseases of the nasal accessory sinuses and teeth. To save time I omit disease of tonsillar and otitic origin from the group. Neuritis, supposed to originate in infected sinuses or apical dental abscesses, has attracted much attention in the last few years. These cases are not only of peculiar interest to the throat, nose, and ear specialist and the dental surgeon, but also to the bacteriologist, who has taken a considerable part in their elucidation. It is stated in authoritative works that over 50 per cent. of nasal sinus trouble shows optic neuritis, and again that half the cases of unilateral optic neuritis are of nasal origin. Large numbers of papers on this topic have been published during the last three years, and Onodi's dissections show how nasal sinus disease may affect the nerve because of its contiguity. For the most part the cases we see are direct extension of inflammation to the cellular tissues of the orbit or through the large venous anastomoses which connect up the sinuses with the orbit. These are of course usually unilateral. Abscess of the orbit is quite common here, especially in children. It is very frequently mixed up with other conditions, and on this account many children lose their eyes from subsequent atrophy because the pus is not evacuated in time. The majority of cases of unilateral acute proptosis in children is due to abscess (this is not so in adults).

Local extension by venous or lymph channels may also take place from dental foci via the pterygoid plexus and the periosteum; but, apart from those cases in which there is an obvious local extension, a definite bilateral papillitis may sometimes be observed at the disc in which one must consider not only a local process originating in both nerves posteriorly (for example, posterior sinus disease), but also the possibility of a blood stream infection—the so-called focal infection.

A recent case showed a bilateral neuritis associated with considerable contraction of the fields and sectoral changes in the colour fields in which the only obvious cause was apical abscess. On removing the several teeth involved there was an immediate drop in the vision, which not only pointed towards the true cause, but taught one to be careful about stirring up extensive foci of infection. It would probably have been better to remove one tooth at a time.

As regards the reality of the connexion between apical abscess and eye disease, Benedict's work illustrates the way in which investigations in this field are dependent on the co-operation of bacteriologist, radiologist, dentist, nose specialist, and ophthalmologist.

Last year we had several very satisfactory cases in which drainage of infected sphenoidal cells was attended with clearing up of a neuritis. Here I must sound a note of warning to those who are unfamiliar with exploratory procedures of the nasal sinuses. Cushing, in a paper published in 1920, emphasizes the danger of these operations in the hands of the unskilled. My experience of a number of cases has been that, if there is obvious disease of the accessory sinuses associated with bad drainage, the smallest operation compatible with good drainage should be performed. The very gross cases of purulent sinusitis which are not uncommonly met with in Madras are to my mind more frequently

associated with globe trouble, such as unilateral scleritis and uveitis or cellulitis. If there is no obvious disease the smallest exploratory procedure compatible with an accurate diagnosis is indicated. I have seen no bad results from a careful extension of the sphenoidal ostium downwards, and at least it precludes retention in this all-important space. Indiscriminate cutting operations in the nose are without doubt almost as criminal as is a wholesale extraction of teeth on account of a suspected focal infection.

There are so many points in connexion with optic atrophy which interest the physician that it is difficult to pick out types for discussion. As regards general paralysis, it has been suggested to me by an eminent mental specialist that general paralysis is often missed in India. In this city I rarely see it. In the following two cases there was practically complete loss of vision in association with extensive central nervous system syphilis of a congenital type.

In one the partial atrophy is of a decidedly post-neuritic type, in the other it is of a primary or simple type. In the first case there was extensive neuritis and extensive paralysis. When we first saw this boy he was blind except for perception of light. Colonel Elwes, first physician, General Hospital, kindly took over the case. The patient is now able to see perfectly well and can get about. He has contraction of the fields, a slight degree of optic atrophy, but gets 6/5 central vision in each eye. He has a certain amount of spastic paralysis of the limbs, he is slightly deaf, has not had interstitial keratitis, but has the characteristic teeth.

In the other case the atrophy is of a simple variety, there has never been papillitis, the gait is of a spastic type, reflexes are increased, and vision is markedly reduced. The teeth are not in any way typical, but the two other members of Hutchinson's triad are present—the deafness and remains of an interstitial keratitis.

Finally, I mention the association of optic atrophy with the meningitides of childhood. We very frequently see double optic atrophy in children, either simple or post-papillitic, and as often as not we get a history of fever or fits preceding the onset of bad vision. The history is unreliable, and as in this hospital we do not come in much contact with the diseases of children, I would be very glad to obtain the views of general practitioners or physicians on the subject of meningitis occurring in children in which recovery takes place but which is followed by optic atrophy.

## DIPHTHERIA CARRIERS.

BY

LIEUT.-COLONEL F. W. SUMNER, M.D. CANTAB.,  
F.R.C.S. EDIN.,  
INDIAN MEDICAL SERVICE.

An outbreak of diphtheria occurred at a school in Simla in March, 1922. Eight cases occurred from March 14th to 23rd: they were all from the same source of infection—a boy who arrived from Karachi in March suffering from diphtheria; the others were direct contacts.

Sporadic cases occurred on the following dates: May 19th, 1; July 3rd, 1; July 7th, 1; September 9th to 19th, 4. There were 15 cases in all with one death (case of May 19th).

The interest in this outbreak lies in the question of carriers and what factors go to make "healthy carriers" as apart from "disease carriers." By the former I mean those who have shown no symptoms of the disease, and yet who have present in their throats diphtheria bacilli; by the "disease carrier" I mean those who have had a definite attack of diphtheria and have entirely recovered except that throat swabs still show the presence of diphtheria bacilli.

In this outbreak the whole school of 200 boys were given, in March, prophylactic injections of diphtheria antitoxin, and, later, as cases occurred, all contacts were given further prophylactic injections.

In the first batch of 200 there were roughly 5 per cent. who, after some days, developed mild anaphylactic symptoms (rashes and painful joints); after the subsequent injections this percentage increased to roughly 10 per cent., with rather more pronounced symptoms, but nothing of the nature of anaphylactic shock, nor, indeed, any such symptoms as to cause a moment's anxiety.

On May 20th examination for "disease carriers," by taking three consecutive daily swabs instead of the usual one from each of the eight cases who had recovered from diphtheria, showed one to be an intermittent carrier. On the occurrence of the cases in July a further examination of these cases, the three being increased to six consecutive daily swabs,

showed that six out of the original eight were intermittent carriers: these were duly segregated.

On September 9th, after two months' interval, another sporadic case occurred; all possible disease carriers—on the six day test—had been segregated; there was no other known source of infection. The health officer and I decided that it would be to the interest of the boys, in the presence of this unknown source of infection, to advise the governors to close school; we were of opinion that the school drains had nothing to do with the infection.

I decided to examine the throats of all the schoolboys and also the menial establishment with their families, and to mark down for bacteriological examination all those who had reddened throats or large tonsils. There were 59 such cases; one was an ambulatory case of mild diphtheria, both tonsils being covered by a creamy membrane; he was unaware that he was ill; his throat swab was positive; he had the signs and symptoms of a mild diphtheria. Of the remaining 58 cases 50 per cent. proved to be carriers. A few of the remaining 141 boys were examined as these had to remain behind for an examination, the remainder returning to their homes.

Thus one may say that of the 200 boys 15 contracted diphtheria, and out of the remainder (*plus* 14 of these) 80 were examined and 40 found to be carriers. Some 250 prophylactic injections of diphtheria antitoxin were given.

What are the facts of this condition of things? The drains had been the same for twenty years and no such epidemic had occurred before; the source of infection was the boy from Karachi; prophylaxis had been done on a large scale; an injection of diphtheria antitoxin neutralizes some or all of the toxins of any diphtheria bacilli present and thus prevents more or less the symptoms of diphtheria arising, but does not kill the germs that may be present—diphtheria bacteriolysin would be necessary for that purpose, but is not available in India.

We are driven to the conclusion that prophylaxis is a two-edged sword. We must, on the outbreak of diphtheria, give prophylactic injections to all contacts, but where antitoxin only is used it behoves us to be on the look-out for a crop of diphtheria carriers as a result. A recent bacteriological examination<sup>1</sup> carried out at the Royal Hospital for Sick Children and the school clinics, Liverpool, on a series of tonsils removed at that hospital, showed that in 30 per cent. diphtheroid bacilli were present. It is very probable that there is quite a considerable percentage of the public at large who are diphtheroid carriers.

From a clinical point of view there are three types of cases of "sore throat": (1) Where the clinical manifestations of a diphtheritic throat are present and where the bacteriological report is positive. (2) Where the clinical manifestations of a diphtheritic throat are present but where the bacteriological report is negative. (3) Where there are no clinical manifestations of a diphtheritic throat and the bacteriological report is positive.

Classes (1) and (2) must both be regarded as diphtheria and treated accordingly. It is of interest that of the 15 cases of diphtheria which occurred during this outbreak there were two pronounced negative bacteriologically, and one of these was the only fatal case of the series; there was no error in technique in putting up the throat swab or delay in incubation of a smear from it.

As regards class (3) it is possible and probable that such cases are merely some inflammatory condition of the nasopharynx, and the bacilli found are non-pathogenic and non-causative of the condition; clinically there were several such cases in this series, which were nevertheless looked on and treated as diphtheritis.

THE Gifford lectures delivered in the University of Aberdeen in 1921 and 1922 by Dr. E. W. Hobson, F.R.S., Sadlerian Professor of Pure Mathematics in the University of Cambridge, will be published in a volume this summer by the Cambridge University Press. In the lectures an attempt was made to settle the relation of "that complex of knowledge and ideas which is denoted by the term Natural Science" to religion and philosophy at the present day. The author has examined the historical development, aims, and true characteristics of the various departments of natural science, and arrives at the conclusion that many men of science have exaggerated our dependence on natural science in our general outlook on the world and in present-day thought.

## Memoranda:

## MEDICAL, SURGICAL, OBSTETRICAL.

ACUTE AMOEBIC DYSENTERY IN A MAN WHO  
HAD NEVER BEEN OUT OF ENGLAND.

ALTHOUGH cysts of *Entamoeba histolytica* have been found in a small percentage of cases in persons who have never been out of England, yet acute amoebic dysentery is very rarely seen. Dobell says: "I do not believe that more than 10 per cent. of persons who become infected with *Entamoeba histolytica* ever suffer to any appreciable extent from their infection; and I think it very probable that even this is much too high an estimate." A few cases of acute amoebic dysentery occurring in persons who have never left England have, however, been recorded. Marshall in 1912 and Worster-Drought in 1916 each described a case.

A. C., transport driver R.A.F., aged 19, lived in a village in Dorset. He joined the R.A.F. eighteen months ago, and was stationed at Uxbridge, then at Manstone (Margate), and finally at Lee-on-Solent.

Neither he nor any of his family has had dysentery. He was well till February, 1922, when diarrhoea commenced. He did not report sick. Two days after returning to his home on holiday (August 6th) he first noticed blood and mucus in the stools, and these became more frequent and were attended with considerable pain. He was admitted into the Royal Victoria Hospital here on November 7th, 1922. As he did not respond to any treatment, Dr. Turton, the house-surgeon, sent me a freshly passed stool for examination on January 12th, 1923. This was of the consistency of pea-soup, of a deep brown colour, and almost homogeneous. In it I found numerous active amoebae, many of which contained several red blood corpuscles.

Films were made subsequently from small blood-stained masses, and were fixed whilst wet with corrosive sublimate and alcohol, with and without the addition of acetic acid. They were stained with iron haematoxylin, Mann's methyl blue, and eosin, and with Giemsa's stain. Many of the amoebae contained red blood cells, and the nucleus had a delicate achromatic membrane lined with chromatin granules, and had a small spherical karyosome in the centre.

Having made quite certain of the nature of the disease, Martindale's capsules of emetine bismuth iodide (gr. iii), once a day, were given for twelve days. All the patient's symptoms, which had been in existence for eleven months, ceased, the stools became solid, and he gradually regained his strength.

Numerous examinations were subsequently made, but no cysts of amoebae were found.

I can only conjecture that his infection was from *Entamoeba histolytica* cysts of some carrier in the R.A.F.

## AIR-BALL IN TRACHEA.

The following account of a case of death from asphyxia may be of interest.

A. S., aged 6 years, was brought to the Metropolitan Hospital dead on the evening of March 5th, 1923. There was a history of the child having swallowed a toy balloon some few minutes previously. The lips, face, and finger-tips were intensely cyanosed.

The necropsy revealed that the balloon was lying in the trachea, at its bifurcation, and that the mouth-piece of the balloon was projecting into the right bronchus. The position of the balloon was such that any attempt by the victim to expel the balloon would have resulted in air from the right bronchus passing into the balloon and inflating it.

JAMES I. LYONS, L.M.S.S.A.,  
Casualty Officer, Metropolitan Hospital.

## COLLOID ARGENTUM IN RUPTURED PERINEUM.

It often happens in midwifery practice that, in spite of every care and attention at birth, the torn perineum refuses to heal after being sutured. For this reason I desire to bring to notice my experience with colloidal argentum.

Recently I had a bad forceps case with a rigid perineum; early rupture of the membranes took place; the perineum was torn from the fourchette to the sphincter ani (but not involving it); there was also a lateral tear into the left labium, which bridged across the head in its descent and required cutting before the head was born.

Several sutures (silkworm gut) were used, but all had to be taken out on the third day as they had become sodden. I told the nurse

on the following day to paint the raw surfaces with equal parts of "Oscol" argentum and distilled water night and morning, and I then put in three catgut sutures. A fortnight after the date of labour the surfaces had come together and the patient was able to get about.

It is more than five years since I first used a similar preparation in a case accompanied by gonorrhoeal vaginitis and obtained satisfactory results. Since then I have used it in cases where stitches have failed owing to septic changes, or had become absorbed before the perineum was healed; in some cases I inserted fresh catgut sutures as late as the fifth or seventh day after labour. In every case I have had complete satisfaction. Instead of having a glazed surface when the torn perineum has failed to unite after primary suture, by simply applying the colloidal argentum it has produced raw bleeding surfaces, which have knit together very quickly.

It may be argued that the torn surfaces would probably have healed without any applications, simply because they were kept clean; but I do not think that catgut sutures inserted, for the second time, a week after (as has happened in a case of mine) would have done their work so well.

Nottingham.

## BRONCHOPNEUMONIA IN A CENTENARIAN.

A CENTENARIAN is rather a *rara avis*, so that the following notes on a lady of 103, who recovered from a moderately severe attack of bronchopneumonia, may be of interest.

Mrs. C. had been bed-ridden for some years as a result of an injury eight years ago, but had retained her memory and mental alertness; she had enjoyed good health until March 1st, 1923, when she contracted a chill.

I was called to see her on March 7th; she was flushed and restless, and suffering from a harsh, dry cough with short, rapid respirations. The temperature was 103°, the pulse 140, and the respirations 44. There were sordes on the tongue and lips. Examination (which was superficial, owing to her condition) revealed harsh rhonchi all over both lungs, with an area of diminished resonance, crepitations, and some bronchial breathing in the left base in the axillary line.

For six days her condition was critical, then defervescence gradually set in, and by the end of a fortnight convalescence was fairly established.

On April 5th, however, senile gangrene began in the right foot and four days later the patient died.

Strathpeffer, Ross-shire.

## SYPHILIS INCONTINUIT IN SCHOOL CHILDREN.

The following three cases of accidental acquired syphilis, which were recently seen at Cardiff School Clinic, are recorded as pointing to the prevalence of this condition in children and the possibility of the disease being overlooked:

A boy, aged 13, was brought by his sister who said he had ringworm. On further questioning she stated that he had sores between his legs and that there had been a sore there some three months previously for which ointment had been used. On examination he was found to have very marked syphilitic alopecia, anal condylomata, and general adenitis. The Wassermann reaction was positive and well marked.

A boy, aged 13, was reported as suffering from impetigo and ringworm and had been treated as such for some weeks. There was a somewhat indefinite history of a sore on the tongue four months previously. At the time of examination alopecia was very marked, and there was a serpiginous scaly rash on the scalp, trunk, and limbs, impetigo in places, especially on the scalp, and general adenitis. The Wassermann reaction was positive and well marked.

A boy, aged 12, according to his mother, had had chicken-pox (? pustular syphilide) a week or ten days earlier, and was now suffering from ringworm and sores on his body. On examination he showed a copper-coloured squamous syphilitic resembling psoriasis, impetiginous areas on scalp, alopecia, general adenitis, and ulceration of the mouth and left tonsil. The Wassermann reaction was positive and well marked. The mother remembered the boy having a sore in his mouth and swollen glands in the neck some months ago.

All the cases cleared up rapidly after a course of novarsenobenzol injections and grey powder at the venereal disease clinic.

The source of infection was not definitely traced in any of these cases, although the home condition of one of the boys was very unsatisfactory. The superficial resemblance which the cases bore to ringworm, impetigo, and psoriasis diverted attention from the possibility of secondary syphilis, and it was only after a more complete examination that the true nature of the disease was established.

Assistant, Cardiff V.D. Clinics.

## Reports of Societies.

### MANGANESE IN CHEMOTHERAPY.

At a meeting of the Dermatological Section of the Royal Society of Medicine, with the President, Dr. H. G. ADAMSON, in the chair, Mr. J. E. R. McDONAGH read a paper on manganese as a chemotherapeutic agent. He said that clinical experience with arseno-benzene led him to believe that the drug did not attack the *Leucocytozoon syphilidis* directly, but indirectly through the protein particles in the plasma. Seeking an explanation of the action of chemotherapeutic drugs he came to the conclusion that metals acted as catalysts in the oxidase reaction and non-metals as catalysts in the reductase reaction; further, that metallic preparations increased the number of protein particles and augmented their negative charge, while non-metallic preparations caused the protein particles to agglutinate and diminished their electric charge; in short, that metals acted as conductors of electricity and non-metals as condensers. Micro-organisms behaved in varying degree as condensers; thus among coccogenic bacteria the staphylococci were the most feeble, and of protozoa the *Leucocytozoon syphilidis* was the most potent. Conduction increased the number of the protein particles, diminished their size, hastened their movement, and augmented their negative charge. This meant that the expanse of surface exposed to the parasites was increased enormously and the additional negative charge enabled the protective substance to turn the tables on the parasites. If the parasites lost sufficient negative electricity they underwent lysis and were destroyed. All the immunity tests were based on the electrical relationship between the protective substance and the micro-organisms. As the conductor action of metals varied much, and as the nature of a metallic compound influenced its conductor effect, tests were devised to determine the degree of dispersion that could be produced, and several compounds were tried, first in simple and then in complex infections. Some idea of the conductor action of a metallic preparation could be judged by its ability to accelerate coagulation. Conductors parted with their electrons, and these, when taken up by Gram-positive micro-organisms, changed them to Gram-negative; the better the conductor the more rapid the change. Conductors raised the suspension stability of the blood and increased the percentage of blood-sugar in the plasma. Condensers diminished the number of particles and caused them to increase in size and agglutinate; retarded coagulation; made Gram-negative micro-organisms Gram-positive; and caused a fall in the percentage of blood sugar. The most suitable conductor was manganese, which in its colloidal hydroxide form was useful in the simplest infections. With the hope of finding a preparation equally beneficial in streptococcal and gonococcal infections he experimented, and found manganese butyrate the most efficient. In simple infections the degree of conduction required was not great, but there must be no condenser action. A 1 per cent. solution of manganese butyrate fulfilled these requirements. Of this preparation never more than three injections should be prescribed in any one course. In his experience two injections sufficed, and these should be injected intramuscularly in 1 and 1.5 c.cm. doses respectively, with three or four clear days' interval between them. Manganese butyrate was valuable in boils, carbuncles, erysipelas, whitlows, lymphangitis, and lymphadenitis, and useful in acute gonococcal urethritis, abscess formation, epididymitis, and in gonococcal septicaemia if given early. In septic conditions, including tonsillitis, quinsy, and even rhinitis, manganese butyrate should be given a chance before an incision is made. If prescribed in time the lesion would abort, while if pus had already formed a single injection would bring it to a head. The pus should be evacuated through a small incision, and dry dressings and not hot fomentations applied. In operations on septic bones and joints manganese butyrate expedited healing.

Dr. H. G. ADAMSON (President) confessed to great difficulty in following Mr. McDonagh's arguments clearly. Many of his theories were not supported by sufficient evidence, but he (the President) was not really competent

to offer any material comment, and he would be glad to hear remarks from others, particularly from those more conversant with biochemistry. On the practical side he congratulated Mr. McDonagh on having obtained in the long list of cases of different types of coccic infection the good results with manganese butyrate which his theories had led him to expect. He hoped these good results would be confirmed by the experience of others, and that manganese butyrate would prove to have the value in the treatment of lupus vulgaris which was predicted for it.

Dr. A. M. H. GRAY said he did not pretend to understand the elaborate experiments Mr. McDonagh had made in this research. His own experience of manganese had not been so favourable as that of Mr. McDonagh. He (Dr. Gray) found that in a case of boils which responded well to manganese almost miraculous results could be obtained from one or two injections, and, on Mr. McDonagh's advice, he had never given more than three injections, at two or three days' interval. But he had often found that some weeks afterwards there was a relapse, and then, at that stage, the giving of more colossal manganese produced no benefit. That occurrence did not seem to fit in with the explanation Mr. McDonagh had given. He was interested to hear from Mr. McDonagh that colloidal manganese contained no peptone, because he had assumed that one was not dealing with the effect of manganese at all, but with protein shock, which had a great effect on lesions of that type, but generally failed to bring the result off a second time.

Dr. HALDIN DAVIS said that Mr. McDonagh had once more given the profession a remedy of considerable value, as he had done when he introduced collosol manganese, which he (Dr. Haldin Davis) had used a good deal and with gratifying results. Having listened to Mr. McDonagh he was quite prepared to admit that manganese butyrate was probably a very useful remedy; but he failed to follow the arguments by which he supported his theory of the action of this drug; Mr. McDonagh employed a terminology entirely his own. He used the terms "condensation" and "dispersion" to denote some electrical change in the blood and tissue fluids, but he had not indicated how he measured the electrical changes thus adumbrated. He had said that a change of an electrical nature had in one direction caused a quicker coagulation of citrated plasma, while a change in another direction caused a diminution of the blood sugar. He (the speaker) was unable to follow the correlation between those changes and the postulated electrical phenomena. His opinion was that Mr. McDonagh very likely had found a useful remedy, but the discovery had really been made by the old method of trial and observation, and that its action was by no means due to electrical changes, which had never been actually demonstrated to be caused by its administration.

Mr. H. FINKLESTONE-SAYLISS summarized the results of treatment by manganese butyrate at the London Lock Hospital.

Mr. McDONAGH, in his reply, said that it had never been suggested to use manganese butyrate in lupus vulgaris. The clinical results with the butyrate were much superior to those with the hydroxide, especially in gonorrhoea. As for the criticisms of his paper, these could not be answered without reiterating what he had just read. No words had been coined, and the subject was extraordinarily simple, as he believed most would find when reading the article at leisure. He believed he was the first to find out that arseno-benzene did not attack the syphilitic micro-organisms directly, but indirectly through the protein particles in the serum.

### PELVIC ADENOMYOMATA.

A MEETING of the Obstetrical and Gynaecological Section of the Royal Society of Medicine was held on May 3rd, with the President, Dr. T. WATTS EDEN, in the chair. Dr. ARCHIBALD DONALD read a paper on the clinical aspects of adenomyomata in the female pelvic organs. He suggested that it was necessary first to get clear on the question of terminology. An adenomyoma was a tumour composed of glandular and muscular elements. The glands were lined by columnar cells, and were surrounded by, or rested on,

unstriated muscle cells and a stroma of small cells. The name "endometrioma" had been suggested. It were better not to use the term, since it implied the acceptance of a theory as to the mode of origin of the growths. Nevertheless there was no doubt that in some cases the elements in adenomyomata behaved like those in the endometrium. Sometimes the "cystogenous tissue" took on a decidua reaction during pregnancy, and in many cases the spaces were filled with altered blood—the result of haemorrhage during the menstrual periods. Other writers, again, believed that adenomyomata of the recto-vaginal space were the result of inflammation, and the strange term of "adenomyositis" had been invented.

Adenomyomatous growths were not confined to the female pelvic organs. They had been found in the intestinal canal and in the umbilicus. In the pelvis they were found in the uterus, the round ligaments, Fallopian tube, ligament of the ovary, the ovary, and recto-vaginal space. They might be present in only one of these positions, in more than one, or even in all six simultaneously. Probably the order of frequency was: ovary, pouch of Douglas, and less commonly the other structures, including the uterus.

He wished to make some remarks on the infiltrating ovarian cyst with tarry contents. Frequently these cysts were associated with adenomyomatous growths in the recto-vaginal space. They were situated on the back of the broad ligament, were often bilateral, never attained great size, possessed powers of infiltration or dissection, but were not truly malignant. They contained somewhat thick viscid contents of a tarry or chocolate-brown colour. These were now recognized—and the microscope confirmed the finding—as adenomyomata of the ovary, and it seemed probable that in some cases adenomyomata of the pouch of Douglas were derived from them, just as warty growths of the peritoneum were caused by a rupture of a papilliferous ovarian cyst.

Turning to the clinical side, the lecturer described 16 cases which had occurred in his practice in 1922. The youngest patient was 23 and the oldest 47. None had reached the menopause. Two were single. Of the 14 married patients 5, or nearly one-third, had never been pregnant. Of the 9 remaining, 5 had had one or more miscarriages. These figures seemed to indicate a relation between adenomyoma and sterility and abortions. The symptoms of adenomyomata were dysmenorrhoea, pain or pressure in the rectum, and dyspareunia. Dysmenorrhoea was the most common. It was usually most acute during the first day or two of the period. Profuse haemorrhage at the periods was complained of in 7, or nearly half the cases, but there was reason to believe that it was not a symptom of adenomyoma (unless the growth was in the uterus), but was due to some other coexisting condition of the uterus. The physical signs were: (1) Hard or irregular swelling or nodules felt through the posterior fornix. The nodules were generally not much bigger than a pea and might be smaller. (2) Indefinite resistance at one or both sides of the uterus, and sometimes definite enlargement of the ovary. (3) Retroposition of the uterus and limitation of mobility. Sometimes only one of these signs was discovered. Very acute dysmenorrhoea beginning before the onset of the period or during the first day, and often coming on some years after establishment of the periods, was very suggestive. Pressure on the rectum and acute dyspareunia were also important.

The operations performed varied in severity.

In 12 cases panhysterectomy or subtotal hysterectomy, with dissection of adenomyomatous growth from the pouch of Douglas or rectal wall.

In 1 case removal of one ovary and dissection of nodules from uterus and rectum.

In 1 case removal of fibroid by myomectomy, separation of rectum, and dissection of small adenomyoma from the rectal wall.

In 1 case removal of tarry ovarian cyst.

In 1 case dissection of recto-vaginal growth only.

He believed that adenomyomata were much commoner than was generally thought. Cases were often taken for pelvic inflammation or infected ovarian cysts. The ordinary blood cyst of the ovary was not adherent and was filled with normally coloured clotted blood or with fluid not having the viscid consistence of the contents of the tarry cyst. At operation the existence of adherent cystic ovaries

with viscid tarry coloured contents was present in 75 per cent. of cases. Adhesion of the rectum to the lower part of the uterus and the obliteration of the pouch of Douglas was practically always present in recto-vaginal adenomyoma, and after the adhesions were separated, if there was not found a distinct mass, the hard, round, little bodies could be felt.

The diagnosis before operation was not very difficult. The indefinite swelling on each side of the uterus indicating tarry ovarian cysts, the retroposition and limited mobility of the uterus due to adhesions of the rectum, or the hard irregular mass or round nodules, like gunshot, were all suggestive if not conclusive. Severe dysmenorrhoea was also very suggestive.

With regard to the type of operation necessary, he believed that when both ovaries contained tarry cysts and there was a mass or some nodules in the recto-vaginal space a panhysterectomy was indicated. So was it when only one ovary was diseased, but there was a large mass uniting rectum and uterus. If one ovary only was affected and there were merely small nodules in the pouch of Douglas, removal of the affected ovary and dissection of the nodules after separation of the rectum might suffice; but afterwards a careful watch was necessary. The conservative method applied still more to those cases where only one or two nodules were found in the recto-vaginal space.

Dr. H. R. SPENCER did not think the large cysts such as had been described were always adenomyomata of the ovary. Sometimes they were corpus luteum blood cysts.

Dr. HERBERT WILLIAMSON questioned the wisdom of leaving small pieces of the growth adherent to the rectal wall when complete removal would necessitate opening the rectum. He thought the growth would recur if in part left. He strongly advocated the use of x rays and radium in these cases.

The PRESIDENT thought that the reason there seemed to be no trouble with this condition at the menopause was that at that time the growth retrogressed.

Mr. L. P. PUGH afterwards read a paper on ovarian disease in cows.

## CEREBRAL TUMOUR.

At a meeting of the Section of Pathology of the Royal Academy of Medicine in Ireland, held in the Royal College of Surgeons on April 20th, with the President, Dr. W. D. O'KELLY, in the chair, Professor BOXWELL described a case of brain sarcoma.

The patient, a boy aged 4½ years, was admitted to hospital, suffering from convulsions. After a hot bath he recovered. Later on, he was brought back, suffering from another attack of convulsions; this time a hot bath did not cure him, and he had to be given chloroform. Before the attack of convulsions, the child had been very lively, very talkative, and rather precocious for his age. While in hospital, he vomited any solid food, and had severe headaches. When spoken to, he would answer intelligently, but his cerebration became slow and he would not answer for a considerable time after he had been spoken to. His pulse remained at 90, blood pressure 80, and temperature normal. The cerebro-spinal fluid was examined. It was under considerable pressure, but contained no cells. Later, he could only just tell light from darkness, and before he died he was absolutely blind. He died after eight weeks in hospital. The brain showed an extensive cellular infiltration extending under the pia. This consisted of round cells apparently sarcomatous, and he believed that he could trace their origin from the choroid plexus of the fourth ventricle.

Professor Boxwell added that he had called this case one of brain sarcoma, though he thought it might be a case of endothelioma.

The PRESIDENT remarked that the fact that the illness lasted only eight weeks was specially interesting. Dr. T. T. O'FARRELL could not see any connexion between the small tumour in the roof of the fourth ventricle and the main tumour. He had carefully examined the sections which Professor Boxwell had brought down, but he could not see any connexion between the two tissues. He would like to know if the question of chloroma had been considered, and what was the colour of the tumour before it went into formalin. Dr. J. T. WIGHAM said that it looked to him as if the cells in this tumour were very like those covering the choroid plexus, and that it was quite possible that Dr. Boxwell's suggestion of origin was correct. If that was so the tumour

might easily be endothelial in origin, although the cells were like those of a round cell sarcoma. Professor BOXWELL, in reply, said that the tumour was perfectly white in colour.

#### Two Unusual Cases.

Sir JOHN MOORE read notes on (a) a case of pneumonia with untoward sequelae; (b) carcinoma ventriculi, with unusual secondary developments.

The first patient, a girl aged 18, was admitted to hospital on January 1st, 1923. She had been ill for five weeks, suffering from what was stated to be pneumonia, which had started suddenly. This illness had apparently told severely on her, as on admission she was very thin and pale. She had a persistent cough, and sputum was brought up in abundance. On examination, Sir John Moore decided that it was a case of acute pneumonia which had failed to resolve, and that the outlook pointed to either pulmonary abscess, or supervening tuberculosis. The sputum was examined three times for tubercle bacilli, but each time the report was negative. A Widal test was carried out, and also proved negative. An exploratory puncture in the dull area over the base of the left lung was made twice, but without tapping any collection of fluid. The liver was greatly enlarged. Towards the end of January, the patient's condition became critical. She steadily lost strength and flesh. The lower limbs became anasarctous, and severe pain set in in the right thigh, apparently due to thrombosis, which finally extended up to the inferior vena cava. The breath and sputum were fetid. On February 20th a pleural friction rub was detected over the base of the right lung. The temperature became subnormal on February 24th, and remained so till the death of the patient, on February 27th. At necropsy the findings reported were: Abscess in (a) liver, (b) spleen, (c) left perinephric region, (d) lower lobe left lung. Oesophagus, liver, left lung, left kidney, all adherent to diaphragm. Pus from the liver abscess contained long chains of streptococci. Tubercles were found in the liver, which was extensively infiltrated with fat.

The second patient, a woman aged 56, was admitted to hospital on March 3rd, 1923. She was extremely emaciated, and wore a look of great physical suffering. She had been complaining for nearly a year of gnawing pains over the upper part of the belly, which was very tender on pressure. The pains at first were of a shooting character, but later were of a dull and gnawing character, and kept her awake at night. She was also suffering from loss of appetite, vomiting, constipation, and costiveness. Some months before admission she began to lose flesh rapidly, and during the first nine days in hospital she lost two pounds. Any attempt to take food brought on sickness, and she vomited frothy stuff, and, on two occasions, blood. Her pulse rate was persistently quick, 100 to 120, respirations 24 to 26, and temperature usually subnormal. On examination, a tumour in the lower part of the epigastrium, near the middle line, was found, and enlargement with hardness of the inguinal glands. A diagnosis of carcinoma of the stomach was made, and the case was pronounced to be inoperable. A screen examination of the stomach and duodenum was made, which confirmed the diagnosis. The patient lived until March 25th, when she collapsed suddenly, and died quickly of haemorrhage into the stomach. The *post-mortem* findings were: When the peritoneal cavity was opened, there was an escape of a large quantity of clear, straw-coloured fluid. The falciform ligament was greatly thickened, and was hard and nodular. The gall bladder was adherent to the duodenum. The pyloric end of the stomach was firmly bound down by dense adhesions. The spleen was closely adherent to the greater curvature of the stomach. The peritoneum had a number of nodules scattered over it, and there were several enlarged, hard glands in the mesocolon. The liver was rather small, but showed no secondary nodules. The stomach was small, the wall was hard and thickened. On opening, the stomach was found to be full of blood. In the posterior wall, near the pylorus, was a large, crater-like ulcer, with a fungating growth in the centre of it. The diaphragm was studded throughout with secondary growths, some of which were the size of a shilling.

Dr. BAREND VIVIER demonstrated the specimens. There were two abscesses in the first case, one in the liver, and the other in the base of the left lung penetrating the diaphragm and involving the spleen and left kidney.

Dr. T. T. O'FARRELL inquired as to the origin of the sepsis in the first case, and if a blood culture had been done. He also asked if the oesophagus was quite normal, because sometimes foreign bodies were found in the oesophagus and gave rise to conditions like those described. It would be interesting to know what the source of infection in this case was, and if it was a primary focus.

The PRESIDENT said that, regarding the first case, he was satisfied that there was no tuberculous lesion in the lungs, and he was inclined to think that this was not an ordinary case of tuberculosis, on account of the absence of tubercle bacilli in the sputum, but that the tubercles in the liver were a subsidiary chance infection. The second case was extremely interesting. He thought that haemorrhage in such a case was uncommon. The freedom of the liver from any growth was a point of importance.

Mr. HENRY STOKES said that, regarding the first case, before the needle was put into the patient's chest, she was  $\alpha$  rayed. There was, at that time, no pleural effusion, and, according to the  $\alpha$  rays, any abscess must have been small. It had certainly not penetrated the diaphragm.

Sir JOHN MOORE, in reply, said that in the first case no blood culture had been made. He had not looked for any evidence of actinomycosis. He was of opinion that this was really originally a case of pneumonia, and that the infection took its origin in a very seriously damaged left lung. The second case he looked upon as undoubtedly one of ulceration of the stomach, and he thought that this accounted for the illness up to a comparatively short time before death. The fact that cancer of the stomach often supervened on an ulcer was demonstrated in this case.

Dr. T. T. O'FARRELL read notes on cases of (a) cylindroma of parotid region; (b) adeno-sarcoma of kidney; (c) basal cell cancer of neck.

#### GASTRECTOMY FOR PRECANCEROUS ULCER.

A MEETING of the Surgical Section of the Royal Academy of Medicine in Ireland was held on April 27th. Sir WILLIAM I. DE' COURCY WHEELER, who was in the chair, showed a specimen (with  $\alpha$ -ray photographs) of total gastrectomy for precancerous ulcer of the stomach, and discussed the opinions of Rodman, McAuley, and others on the subject.

The patient was a woman, aged 60, who had a history, extending over fourteen months, pointing to a gross gastric lesion. A gastric ulcer was tentatively diagnosed, but was not definitely confirmed after  $\alpha$ -ray examination. On opening the abdomen a deeply excavated ulcer, about the size of a shilling, was discovered on the posterior wall, at the cardiac end. The edges were raised and hard, and the glands around the lesser curvature were enlarged. The age of the patient, the induration of the ulcer, and the nature of the glands at once suggested that malignant change had taken place, and, in any event, it was felt that such an ulcer in an elderly woman should be considered precancerous. Total gastrectomy was performed; de Martel's clamps were used to overcome the technical difficulties of the operation. A loop of jejunum was anastomosed to a fringe of tissue held by the clamp immediately at the oesophageal opening. The specimen showed an ulcer which macroscopically appeared to be malignant, but repeated microscopical sections showed no evidence of malignant change. There was some necrosis, with thrombosed vessels and an unusual amount of inflammatory reaction in the submucous coat.

Sir William Wheeler said that, apart from the generally accepted view that gastric ulcers predisposed in a large number of instances to the development of cancer, it was clear that a type of ulcer existed which would become malignant with almost absolute certainty, and should be treated by the most radical operative procedures. MacCarty in his study of precancerous conditions viewed this question from a histological point of view, but it was not possible to say by microscopic sections that cancerous cells not then present would not be present at a future date. The patient made an admirable recovery and now prefers solid to liquid food.

Dr. T. G. HARDMAN, who had made the  $\alpha$ -ray examination of the patient, showed the films. When an opaque meal was given, a very definite filling effect was shown on the lesser curvature in the recumbent position, but was not present when the patient was in the upright position. Consequently a tentative and not an absolute diagnosis of ulcer was made.

Mr. H. STOKES thought that no other operation than total gastrectomy could have been done.

Mr. W. PEARSON said that the patient made an excellent convalescence. He thought that there had been very little choice of what to do. An alternative to gastrectomy was gastro-enterostomy. He had performed gastro-enterostomy in one such case in which the ulcer felt indurated and the glands were enlarged, and in which it was utterly impossible to attempt excision; the result had been satisfactory; gastro-enterostomy should not always be looked upon as a useless procedure in cases of ulcer in the cardia.

Mr. C. J. MACAULEY considered that unless the surgeon was absolutely convinced that the ulcer was malignant, it was too radical to take out the whole stomach. Though he congratulated the President on the successful way in which he had carried out the operation, yet he felt that this case might have been dealt with by other means.

## Reviews.

### A TEXTBOOK OF DERMATOLOGY.

DR. ROBERT MACKENNA has produced a textbook of dermatology<sup>1</sup> distinctly above the average. It is quite reasonably comprehensive; we have not noticed any important omissions, while properly enough the commoner diseases are given a greater proportion of space than the rarer conditions. The reader is also materially assisted by the plan here adopted of employing type smaller than that used for the main body of the text for the less important conditions. Another good feature is the provision of tables of the diagnostic points of difference for the more important diseases which are liable to be confused with one another—for example, between syphilis and psoriasis, ringworm and alopecia areata, scarlatina and scarlatiniform erythema, and so on. These tables will be very helpful to the general practitioner in enabling him to make up his mind in doubtful cases. The general practitioner will also be glad to know that the subject of treatment is much more fully dealt with than in many dermatological textbooks and in a much more sensible manner. Full prescriptions are given in most instances and detailed directions for carrying out local treatment. Dr. MacKenna is fully alive to the important part x rays now play in the therapeutics of the skin, but we feel that he might with advantage have provided some general directions as to the type of apparatus best adapted for work in this field and some notes as to the technique. He does, indeed, give some of the points which must be taken into consideration in carrying out the Kienböck-Adamson method of epilating the scalp for ringworm, but he omits to state that the distance between the centres of the irradiated areas must be five inches; if the distance be less there is too much overlapping and consequent danger of an overdose. If the directions given by Dr. MacKenna be followed, in the case of a child with a very small head, the irradiated centres will be too close to one another, while on the other hand, if the child has an abnormally large head, the centres will be too far apart, so that there may be insufficient overlapping of the areas, and hence some portions of the scalp will not receive an adequate dose, and the hair will not fall.

The attitude of the author towards new work is praiseworthy. He is evidently prepared to test any new method of treatment which appears to him to offer a reasonable prospect of yielding satisfactory results. For example, he has tried vaccine treatment for ringworm (with the assistance of O. de Jong), and reports that the use of a vaccine produced from ringworm culture prevents the development of fresh areas of infection and reduces the duration of treatment when reliance is placed upon ointments alone. On the other hand, Dr. MacKenna remains critical in the face of investigators who claim the discovery of dermatological panaceas; he is quite alive to the importance of the phenomena of focal infections and sensitization to foreign proteins in the explanation of dermatoses; in fact, he devotes a chapter to the discussion of these interesting subjects, but he exercises caution in accepting them as an adequate solution of the many etiological problems presented by the various erythemata.

Another useful feature developed by the author more extensively than we have noticed previously is the provision of diagrams or charts of the body showing the sites commonly affected by some of the commoner eruptions—for example, scabies, psoriasis, and lichen planus.

Altogether Dr. MacKenna has produced a very useful and practical work, which is the more valuable because it is written in clear and racy language, and is full of details evidently drawn from the author's own extensive experience of dermatology. Occasionally he makes use of a happy and graphic metaphor, but he avoids laboured attempts at facetiousness, which are apt to become somewhat irritating. The illustrations are numerous and practically all original: the reproductions of photographs of cases under the care of the author and his late colleague, Dr. Stopford Taylor, are very good photographs, and in almost every case bring out clearly the points it is desired to illustrate. Dr. MacKenna has avoided the lure of the coloured plate, which may occasionally indeed be brilliantly successful, but which in

practice is usually unsatisfactory. Dr. MacKenna's manual, which is of reasonable size and weight, deserves commendation and recommendation.

### THE PHYSIOLOGY OF THE LIVER.

PROFESSOR G. H. ROGER, the distinguished Dean of the Faculty of Medicine of Paris, has been a life-long worker on the functions of the liver, and has made more than eighty contributions on this subject, dating from 1886, when, under Bouchard's inspiration, he began his series of publications on the antitoxic or protective action of this gland. He is therefore in a good position to give a broad review of its functions in health and disease, as he has done in his monograph, *Physiologie normale et pathologique du foie*.<sup>2</sup> The scope of the subject is enormous and attended with much difficulty, and the author frankly admits that the vast bibliography has not been completely covered; this is perhaps specially noticeable to English-speaking readers, for the author is not always familiar with our names and work—for example, in discussing the nerve supply of the biliary tract he refers to the conclusions of Brainbridge and Dole, and does not mention Meltzer's law of contrary innervation of the gall bladder and Oddi's sphincter at the lower end of the common bile duct, or Rous's work at the Rockefeller Institute on the secretion of bile and the function of the gall bladder. It is, however, natural that this volume should be rather a summary of an investigator's own extensive work and a correlation of it with existing knowledge than the encyclopaedic review of a critical compiler. Professor Roger is, of course, thoroughly familiar with the most recent work of the Paris school that has done so much for hepatic pathology, and constantly quotes it. As professor of experimental and comparative pathology in the University of Paris he is specially well equipped to deal with the pathological conditions of hepatic functions, and he constantly applies the results of experimental research in the laboratory to bedside practice.

After discussing the question as to the existence of jaundice due to the formation of bile pigment in parts of the body other than the liver, Professor Roger concludes that the extra-hepatic formation of bilirubin is as yet too uncertain to be regarded as definitely established. His caution is also shown with regard to the mechanism of the production of urobilin, for after tabulating five hypotheses the decision as to the correct one is left open. Provisionally three forms of jaundice are recognized—namely, obstructive, haemolytic, and that due to disordered function of the liver cells; the first includes emotional icterus due to spasm of the ducts; haemolytic jaundice is subdivided into that depending on fragility of the red blood corpuscles and that caused by changes in the liver, spleen, or other haemopoietic organs. In some instances the disordered action of the liver cells may be an excessive production of bile, as in Hanot's cirrhosis and possibly in spirochaetosis icterohaemorrhagica; in others the constituents of the bile are passed into the blood instead of the bile channels. In the section on the metabolism of fat reference is made to Professor J. B. Leathes's work and to Roger and Binet's observations on the process they call lipodieresis; fats are so acted upon by the blood and tissues as to lose their specific characters and be destroyed; in the liver and lungs this change is ascribed to a ferment lipodierase, the first modification being a transformation of saturated into non-saturated fatty acids. The glycogenic and antitoxic functions of the liver are fully discussed; and the volume, which brings together the author's work in a convenient form, can be recommended as a useful source of reference.

### CAUSES AND CONSEQUENCES.

*Causes and Consequences*,<sup>3</sup> by Sir BAMFYLDE FULLER, is a collection of essays covering a very wide field of thought. There are in all sixteen chapters and an introduction, and a random selection from the titles will indicate the very diverse character of the essays making up the book: "Liberty," "Ultimate facts in economics," "Vocabulary and grammar," "Logic," "Auto-suggestion," "The foundations of morality," "Amusement." It will be at once apparent that each of these subjects—and this applies to the whole of the collection—demands nothing less than a book for its adequate treatment; they are subjects which have been written about

<sup>1</sup> *Diseases of the Skin*. By R. W. MacKenna, M.A., M.D., B.Ch. Edin. London: Baillière, Tindall, and Cox. 1923. (Roy. 8vo, pp. x + 450; 166 figures, 21s. net.)

<sup>2</sup> *Physiologie normale et pathologique du foie*. By G. H. Roger. Paris: Masson et Cie. 1922. (Med. 8vo, pp. 391; 16 figures, Fr. 22.)

<sup>3</sup> *Causes and Consequences*. By Sir B. Fuller, K.C.S.I., C.I.E. London: J. Murray. 1923. (Demy 8vo, pp. x + 231. 12s. net.)

by many people, and it is difficult for the reader to bend his mind to Sir Bampfylde Fuller's highly individualistic angle, since the process involves the conscious repression of masses of pre-existent ideas. This sacrifice having been made, one can walk with the author without coming to blows, although he is very often exceedingly provocative. As example we will quote from the chapter on auto-suggestion:

"Actions and utterances are commonly stimulated auto-suggestively by ideas of them. (But, having thought of a line of conduct, we may follow it automatically, being unaware of the movements that execute it in detail.) In speaking, the ideas which occur to us bring with them ideas of the words which signify them, and these ideas stimulate utterance associatively. The succession is so rapid that we may not catch it, and may imagine that we have thought in words and not in ideas that recalled them. It may be possible to think in words when thought is a memorial repetition. But intelligent thought must be in ideas, for there is nothing in words that can establish intelligent connexions through the unification of samenesses" (p. 78).

This quotation well illustrates the author's tendencies. Whether you agree with him does not matter. If you like him it will be because he has so obviously pursued his own line of thought and is quite fearless in expressing it. If you do not like it, it will be because the utterance lacks the authority of the specialist. But this is begging the question, because the attractiveness of the book lies in the fact that it enshrines just what Sir Bampfylde Fuller thinks about this and that.

Of all the chapters the most successful, from the lay point of view, are those on "The laws of the mind" and "The brain as a laboratory." They should be read consecutively, since the latter is a development from the former. They are clear in thought and in expression, but they require a certain amount of psychological knowledge for their digestion. From the professional standpoint the author does not appear sufficiently to embody the modern work of the experimental and physiological psychologists. The chapter on "The development of art" begins well: "There is a fragrance about art which seems to shield it from analysis." But, having by this sentence jeopardized the life of the whole essay (and if it had been written "the fragrance which is art defies analysis" the essay would have been stillborn), he justifies what follows by saying that: "The spirit of criticism is, however, not dismayed by the impalpable, and the appreciation—or depreciation—of works of art has become a very prominent feature of current literature." Quite so. And how much of it is fruitful? Certainly Sir Bampfylde Fuller carries us no nearer to the burning heart of the matter. "Rhythm," he says, "is not essential to music. The turns and cadences of Indian village chants are as rhythmless as a bird's song." Later in the same paragraph: "The rhythm unit of music is, of course, the bar." There the weakness of his position stands revealed. The Indian chants and the bird's song have no rhythm because they have no bars. Let Sir Bampfylde go to the early English polyphonic writers, and he will find the most free and flexible and natural rhythm, but he will find no bars in the original scores. Bars are a relatively late convention. The true rhythmic unit is the note, from which it follows that music without rhythm is no longer music. Nevertheless, in spite of its defects, and frequently unjustifiable dogmatism, the book merits attention, for it is the work of a man of wide experience, keen observation, and a truly remarkable versatility.

### THE CLINICAL LABORATORY.

So varied is the technical equipment demanded in the routine of the pathological laboratory to-day that a critical selection of the riot of available methods must be welcome. Such a book is *Clinical Laboratory Methods*, by Professor R. L. HADEN.<sup>4</sup> An American publication, it is almost unnecessary to report that the "get up" of the volume—paper, print, and illustrations—is altogether admirable. Equally superfluous is the comment that the subject matter is up to date with the voluminous literature and that the equipment required of such a laboratory is extensive. A little more than half the book is devoted to chemical procedures related to the examination of body fluids, whilst the remainder contains a useful summary of well proved serological, bacteriological, and histological technique amply described. A chapter describing the handling of the colorimeter, the calibration of volumetric apparatus, the preparation of standard reagents, and like laboratory routine will prove not the least useful part.

<sup>4</sup> *Clinical Laboratory Methods*. By R. L. Haden, M.A., M.D. London: Henry Kimpton, 1923. (Med. 8vo, pp. 254; 69 figures, 5 plates. 18s. net.)

The author has been severely selective in presenting only one method for each quantitative determination and has thereby avoided any critical survey of alternative methods. While we may be tempted to regret that he who has given us so excellent a volume does not give us more, we acknowledge that his way is the true economy. And who shall quarrel with his selection where most methods are empirical and so few will survive a decade?

### PHYSIOLOGICAL CHEMISTRY.

*Practical Physiological Chemistry*,<sup>5</sup> by W. W. TAYLOR, and *A Laboratory Handbook of Biochemistry*,<sup>6</sup> by P. C. RAIMENT and G. L. PESKETT, emanate from the medical schools of Edinburgh and of Oxford respectively. Each is avowedly based on the practical course in this subject which the authors have elaborated for their own classes, and we looked, therefore, for such a welcome break with the conventional treatment as might warrant publication. Instead we find the same material presented in the same traditional sequence. Into one hundred pages are compressed the ill assorted collection of tests and estimations of urine, blood, and digestive processes which has too long usurped the place of a real introduction to a knowledge of the part chemistry plays in living processes which is the true biochemistry. The sad truth is—and these publications form a welcome opportunity for renewing the protest—that instruction in this aggressive branch of science is cribbed and cabined by the confines of out-of-date examination syllabuses. These the teacher dare not ignore. The inevitable outcome of illogical curricula is recourse to cramming methods, and the less laborious form of cramming would appear to be to provide the student with a book into which is gathered every operation likely to be encountered in his examination to the exclusion of a connected consideration of fundamentals. The limits of the pocket are such that there is not room even for a practical treatment of the pitfalls which surround the simplest operations, and the worker whose tests will not "go right" will find no help here, whilst the brief statement of such theoretical considerations as are necessary to bind together the patchwork of experiment has led inevitably to many loose and misleading statements.

In spite of all we have said we still believe that these books will be good friends to the candidate in those hectic days before the examination, and—our sympathies being all with the harassed medical student—we will be content to suggest that, with these latest additions to the list, have we not now enough of this sort of book?

### ULTIMATE PROBLEMS OF LIFE.

HUMAN life has often been described as a vicious circle without purpose or aim—a movement from death unto death. Progress thus becomes an illusion, since every advance returns to the point of departure and ends in death. Some such view is presented in a new way by Professor SIGMUND FREUD in an interesting essay, the English translation of which is entitled *Beyond the Pleasure Principle*.<sup>7</sup> The essay is admittedly speculative, and the author describes the development of his central theme as "the exploitation of an idea out of curiosity to see where it will lead." His aim, he says, is to show that contrasted with the life-sustaining instincts there exist still more fundamental "death-instincts" which are directed towards regression and the reinstatement of earlier conditions. He dwells on the universal tendency of organic life to return to the inorganic out of which it originally developed, and maintains that the final goal of all organic striving is to return to the ancient starting point which the living being left long ago. His argument, based upon a number of psychological data, is reinforced by biological considerations. The psychological views expressed in this essay involve some modification of those previously held by Professor Freud. But as he observes at the conclusion of his book, "Only such 'true believers' as expect from science a substitute for the creed they have relinquished will take it amiss if the investigator develops his views further or even transforms them."

<sup>5</sup> *Practical Physiological Chemistry*. By W. W. Taylor, M.A. D.Sc. London: E. Arnold and Co. 1922. (Cr. 8vo, pp. 71. 4s. 6d. net; interleaved 5s.)

<sup>6</sup> *A Laboratory Handbook of Biochemistry*. By P. C. Raiment, B.A. Oxon., M.R.C.S., L.R.C.P., and G. L. Peskett, B.A. Oxon. London: E. Arnold and Co. 1922. (Cr. 8vo, p. 112; 2 figures. 5s. net.)

<sup>7</sup> *Beyond the Pleasure Principle*. By Sigm. Freud, M.D., LL.D. Authorized translation from the second German edition by C. J. M. Hubback. London: The International Psycho-Analytical Press. 1922. (Roy. 8vo, pp. 90. 6s. net.)

### DISEASES OF THE EYE.

It was obvious when the first edition of PARSONS'S *Diseases of the Eye* appeared in 1907 that we had in it a textbook for the student and junior practitioner which would become popular, because it contained exactly what was needed; nothing of importance had been omitted, and the opening chapters on physiology, elementary optics, and the neurology of vision—subjects which many students find rather burdensome—were so clearly written as to be easily intelligible to all. The book has now reached its fourth edition.<sup>6</sup> The text has been revised and some additions have been made; that the book nevertheless is no larger appears to be due to the use of a smaller print than in the last edition; matters of rarity are still treated as before in yet smaller print.

A chapter on preventive ophthalmology and one on the hygiene of vision are new and serve to drive home lessons which are touched upon in the sections on ocular disease. Two new coloured plates and some new figures appear in this edition. The appendix contains, among other matters, a very complete list of the requirements of the public services.

We have always considered this textbook as the best of the smaller handbooks in this or, indeed, in any other language; the new edition strengthens this opinion.

### IN THE MIDST OF MISERY.

It is often asked by laymen why more doctors do not commit their experiences to paper, meaning those intimate glimpses of human life unadorned which it is the medical man's peculiar privilege to obtain. The answer is not far to seek. Given the necessary literary power, any busy practitioner could gather sufficient material for a book out of a single day's work. But who would be interested in it? Only fellow practitioners of a like mind, but without time or ability to write. To the layman it would be only half intelligible; what he wants is a pure humanist version of the unique situations to which a doctor has special access by virtue of his calling.

Thinking that the Gaul, with his smaller measure of reticence, would do these things better than the Anglo-Saxon, we opened *Milieu de Misères*,<sup>7</sup> by S. COURGEY, with lively anticipation. Here is a passage at the beginning of Chapter VI: "On entering I see a woman in a large bed with black hangings. Her uterine cancer, recto-vesico-vaginal fistula, with consequent sciatica, do not give rise, however, to excessive suffering. She lies on her bed and her features give no indication of her terrible malady: Inoperable, she has been many times in and out of hospital." This passage illustrates the whole question at issue. The woman, with her inoperable carcinoma, is the very centre and core of the picture which the author proceeds to paint, yet the full significance of his very vivid description of her can only be perceived by a medical mind. Nevertheless anyone interested in humanity, whether lay or medical, will find these medico-social notes illuminating and interesting. They are sheer realism, no attempt being made to convert the situation to the uses of art, and as such must be commended, for their author is clearly a man of wide experience and ripe wisdom, and he has set down fearlessly what he has seen. The ravages of alcohol, of tuberculosis, all kinds of social evils and complaints fall within his comprehensive view. Fortunately the narratives are not disfigured by any comments; they are allowed to speak for themselves, the author reserving his conclusions for a separate chapter at the end of the book. Here he reveals himself as a deep thinking sociologist.

The book is written in French which presents no great difficulty.

### NOTES ON BOOKS.

A SECOND edition of the *Grundriss und Atlas der Speziellen Chirurgie*, by Professor Dr. GEORG SULTAN, is in course of publication. The first part<sup>8</sup> deals in the main with the surgery of the head, neck, thorax, spinal column, and central

nervous system; it contains some 40 coloured and 245 black and white illustrations. Many of the latter show such advanced stages of disease that they could more profitably be dispensed with, since for teaching the student the art of early diagnosis they are valueless. The teaching on the whole is very much the same as ours, but from the student's point of view more classification and subdivision would be welcome in order to emphasize main points and prevent waste of time in foraging through long sentences and clumsy paragraphs. Two tables for localizing signs and symptoms of lesions of the brain and spinal cord are useful. In operating for epithelioma of the tongue splitting of the cheek is recommended, and for growths far back, instead of Syme's operation, splitting of the lower jaw through the gap of the extracted canine tooth. The approach is made by means of an oblique incision extending from the angle of the mouth downwards and outwards to the point where the facial artery crosses the mandible. In discussing exophthalmic goitre attention is called to the fact, pointed out by Kocher that in the differential blood count the percentage of lymphocytes increases at the expense of the polymorphonuclear cells. In advanced cases the polymorphs fall as low as 35 per cent., whereas the lymphocytes increase to 65 per cent. There is sometimes also an actual diminution in the total white count. Leucopenia has also been observed in cachexia thyreopriva.

A book by M. LOUIS SATOW on *Hypnotism and Suggestion*<sup>11</sup> has been translated into English by Mr. Bernard Miall. The author produces evidence that methods of influencing others and producing trances have been known in all ages, and he gives an account of hypnosis from the remote past until the present time. The main purpose of this book, however, is to show what the author believes to be the baneful influence of suggestion in paralysing the capacity for reasoned thinking. He considers that the suggestive forces which proceed from dogmatic religion, the governmental policy of force, and economic greed have been instrumental in holding the credulous masses in subjection, and the book contains an extremely bitter and biased attack on religious institutions and education. While M. Satow regards it as a difficult task to free mankind from superstition, ignorance, and intellectual servility, he considers there is one excellent method—namely, "the complete and final renunciation of all belief in another world, and the training of mankind, from youth upwards in an atmosphere of free, unprejudiced, critical, scientific thought" (p. 228).

In *New Clinical Methods for the Examination of the Heart*<sup>12</sup> Dr. LUTEMBACHER gives a careful description of the mechanical and radiological methods commonly used in diagnosis. He excludes graphic methods in spite of their importance and interest, because it is a lengthy and difficult matter to obtain a good tracing, and its interpretation requires a certain amount of experience. All, however, should be able to interpret the polygram and the skiagram, and it is to their interpretation rather than to the technique required to obtain them that the text is devoted. The first chapter treats of the anatomy and physiology of the bundle of His, and is illustrated by excellent photographs. The chapters that follow contain a careful and exhaustive consideration of polygraph tracings of normal and abnormal hearts. Clinical features are touched upon only to show the connexion between the tracings and the various forms of arrhythmia met with in patients. The chapters on radiography offer an equally lucid explanation of the phenomena visible with x rays. Each morbid condition is illustrated and excellent diagrams show exactly where and why the heart has departed from the normal in every case.

The *British Goat Society's Year Book for 1923*,<sup>13</sup> in addition to articles dealing with goat breeding, milk production, and other matters connected with goats, contains the following papers of scientific or medical interest: developmental intersexuality in the goat, by Dr. F. A. E. Crow, of the Animal Breeding Research Department, Edinburgh University; sterility in goats, by Mr. H. Stainton, F.R.C.V.S.; the application of indirect calorimetry to goats, by Dr. H. E. Magee, of the Rowett Institute, Aberdeen; and goat's milk for children, by Dr. William Ker Bell.

<sup>6</sup> *Diseases of the Eye*. By Sir John Herbert Parsons, C.B.E., D.Sc., F.R.C.S., F.R.S. Fourth edition. London: J. and A. Churchill, 1922. (Crown 8vo, viii+66; 21 plates, 326 figures. 19s. net.)

<sup>7</sup> *Milieu de Misères*. By S. Courgey. Paris: A. Maloine et Fils. 1922. (Crown 8vo, pp. 240. Fr. 6.)

<sup>8</sup> *Grundriss und Atlas der Speziellen Chirurgie*. Von Professor Dr. G. Sultan. I Teil. Zweite umgearbeitete Auflage. Munich: J. F. Lehmann. 1922. (Crown 8vo, no. viii + 333; 245 figures, 40 plates.)

By Louis Satow. Translated by Bernard Cawlin, Ltd.; New York: The Macmillan Co. 1922.

<sup>12</sup> *Les Nouvelles Méthodes d'Examen du Cœur en Clinique*. Par R. Lutembacher. Paris: Masson et Cie. 1921. (Demy 8vo, pp. 165; illustrated. Fr. 20 net.)

<sup>13</sup> *The British Goat Society's Year Book for 1923*. Compiled and issued by the Honorary Secretary, Thomas W. Palmer, 5, Featherbed Street, London, E.C.3. (Demy 8vo, no. 117; illustrated. 1s. 6d.)

## OCULAR ASPECTS OF PITUITARY DISORDERS.

BOWMAN LECTURE BY DR. DE SCHWEINITZ.

THE Bowman lecture to the recent annual congress of the Ophthalmological Society of the United Kingdom was delivered by Dr. G. de SCHWEINITZ, of Philadelphia, President of the American Medical Association. The lecture consisted of a discussion of certain ocular aspects of pituitary body disorders mainly exclusive of the usual central and peripheral hemianopic field defects.

The lecturer opened with a tribute to the memory of Sir William Bowman, and spoke also of his distinguished predecessors in the lectureship. He thought that although the disorders of the pituitary body had received much attention in this country and elsewhere, certain aspects were still worthy of further consideration.

*Anatomy.*

The first part of the lecture dealt closely with the anatomy of the pituitary region, and detailed the results of investigations made by Dr. Parsons Schaeffer, Professor of Anatomy at the Jefferson Medical College, Philadelphia. Elaborate *post-mortem* examinations and dissections, studied and discussed with the lecturer, led them to the conclusion that many misstatements had been made, particularly with regard to the relation of the optic chiasma to the chiasmatic sulcus. They found direct relation to hold in but 5 cases in the 125 bodies examined. The relations of the chiasma to the sphenoidal sinus, the diaphragma sellae, and the hypophysis itself were examined, and it was evident that in the large majority of cases the chiasma lay so directly over the diaphragma that pressure from growth of the pituitary body of sufficient size would bear upon the crossing chiasmatic fibres. The distance between the chiasma and the diaphragma was found, however, to vary from a potential space to several millimetres, and this factor, combined with the variable thickness of the diaphragma, made it apparent that very considerable enlargement of the pituitary body might be necessary before pressure could be assigned as the cause of visual field changes.

Finally, the vessels of the arterial circle of Willis were considered, and the lecturer showed how the anterior cerebral arteries may become "pressure cords" on the chiasma or optic nerves as the result of crowding from below. Pressure from these or other vessels might account for the production of field defects.

*Possible Production of Toxins.*

While the anatomical conditions might thus readily account for many of the visual field changes, through pressure or traction, or both, upon the optic chiasma, some changes, more especially the scotomata, central or paracentral, seemed to need some other explanation. The lecturer suggested as a more likely factor the elaboration of toxins from the enlarging gland; if they did exist they might reasonably be expected to attack primarily the more highly specialized fibres of the macular bundle. The possible line of attack of such toxins was considered and the lecturer then turned to the many observations made on the visual field changes, emphasizing how frequently the "typical" defects varied. The absence of bitemporal hemianopsia too often diverted attention from the pituitary region, more especially as lateral homonymous hemianopsia was far from "very rare" in disorders of the hypophysis. The various forms of scotomata were reviewed and the similarity between them and those resulting from such lesions as toxic amblyopia and tabes dorsalis was pointed out. Careful plotting of these defects was necessary in differential diagnosis, though the possible association of tabes dorsalis with pituitary disorder had to be borne in mind. The patient often applied for relief from failing vision only in the later stages of the disease, when the visual acuity of one or both eyes had much declined.

*Pituitary Headache.*

Dr. de Schweinitz drew attention to the "pituitary headache" as a conspicuous symptom, showing how it was often less intense than that of other intracranial lesions and less associated with nausea and vomiting. The varying

structure of the diaphragma sellae must play a part in the intensity of the headache, but the lecturer urged the necessity for more general recognition of the pituitary headache as an aid to early diagnosis. Such headache might exist for a long time before any other change, and much time might be lost if the headache were treated along wrong lines, being readily attributed to an error of refraction, gastric disturbance, etc. The possible association between migraine and pituitary disorder was not held to be likely.

*Pregnancy and Menstruation.*

Dr. de Schweinitz spoke next of the physiological enlargement of the pituitary body in pregnancy, and showed from his own observations and those of others that it frequently gave rise to contractions in the temporal visual field. With the return of the pituitary body to its normal size the full field was regained, but repeated pregnancies might leave a permanent defect. In no case had a scotoma been found with or without hemianopsia, and the lecturer suggested that this gave support to the theory of a toxin causing scotomata, no toxin being produced in association with the physiological enlargement of the gland in pregnancy. Objections might, he said, readily be raised to such a suggestion, but they did not eliminate it from consideration as one of the possible causes. After double oöphorectomy similar changes took place in the visual fields but were permanent. No changes in pituitary function were found, and it was suggested that, as in pregnancy, the enlargement was sufficient to cause pressure or traction upon the optic chiasma but insufficient to produce general signs of changed function. The recognized tumefaction of the pituitary body at the menstrual periods could be assigned as the cause of the hemieranias, scintillating scotomata, and transient hemianopsias sometimes observed.

Some persistent types of headache, associated with various physical signs, at about the age of puberty suggested a pituitary disorder, and though such cases showed no contraction on the temporal sides of the visual fields the lecturer considered it worthy of note that relative central scotomata could be demonstrated. The optic nerve head showed congestion, and this again suggested the presence of a toxin, the change differing from that in which only physiological enlargement was presumed.

*The Pituitary in Toxic Conditions.*

The state of the pituitary body in various toxic conditions was discussed, and though the lecturer disagreed with the suggestion that methyl alcohol blindness depended on any pituitary lesion he made some interesting remarks upon tuberculous lesions of the gland, which he said are not infrequent and might have a bearing upon such manifestations in the eye. The interesting condition of hereditary optic nerve atrophy (Leber's disease) might, he thought, be the result of a temporary disturbance in the pituitary, whereby a toxin might be formed which damaged the nerve as a whole or its most delicate part—the papillo-macular bundle.

*Diagnosis.*

Dr. de Schweinitz called attention to the infrequency with which papilloedema was found, and to the peculiar waxy pallor of the nerve head, which had often been described. The x-ray appearances of the sella turcica were considered, and the lecturer laid stress on the fact that the pituitary body might be considerably enlarged without x-ray evidence of change in the sella turcica.

*Treatment.*

The treatment he considered under three heads—glandular therapy and medicinal treatment; radiation (with x rays and radium); and operative treatment. Striking results were shown of glandular therapy with thyroid and pituitary extract, alone or combined with mercurial treatment. Even when syphilis could be reasonably excluded the mercurial treatment appeared to give valuable help to the gland extract. He believed that radiation, held in high esteem by some, aided in the control of recurrence after operative treatment.

It might be a nice point to decide how long such measures should be used before resort to surgical treatment.

The lecturer spoke strongly of the necessity for frequent charting of the visual fields; it was a far surer guide to the state of affairs than repeated x-ray examination of the sella turcica.

Throughout Dr. de Schweinitz illustrated his findings and statements with excellent plates, both of the anatomical relations and of the visual field changes.

## VOLUNTARY HOSPITALS AND MEDICAL STAFF FUNDS.

THE part of the hospital policy of the British Medical Association which seems to promote most discussion, and may perhaps find most difficulty of acceptance by the staffs of certain hospitals, is that dealing with the formation of medical staff funds. It seems well, therefore, that an attempt should be made to set forth the origin and development of the proposal, to describe the present position of the matter, and to summarize the views of the various parties in the controversy.

There can be little doubt that the question of the payment of members of the staffs of voluntary hospitals arose in consequence of the increasing intervention of the State in the treatment of disease. Thus in 1908 the Representative Meeting adopted the principle that "the services of the profession should not be given gratuitously to patients who are maintained by public funds." In 1914 the Association's model scheme for the treatment of tuberculosis was approved by the Representative Meeting, and in that scheme a suggestion for the formation of a special fund, with hints regarding mode of distribution, was included. As a result of the Report of the Royal Commission on Venereal Disease in 1915, the Council of the Association formulated a series of recommendations, including the following: that the services of all members of the medical staffs of hospitals engaged in carrying out the treatment should be paid for by the State or local authority; that special staff funds should be formed; and that certain methods enumerated might be used in the disposal of these funds. These recommendations were passed at the Annual Representative Meeting in 1916.

In the meantime the war was increasing enormously the responsibility of the State for medical treatment; and the voluntary hospitals had undertaken the treatment of soldiers and sailors suffering from diseases or injuries connected with the war. In 1917 the Report of Council extended the recommendations with regard to payment to a staff fund in connexion with tuberculosis and venereal disease, and advised their application to voluntary hospitals treating patients maintained by public funds, leaving to the staffs their voluntary status as regards purely charitable work. At the Representative Meeting at which these proposals were approved it was agreed that the question of payment for the treatment of discharged sailors and soldiers should be referred to the Council.

Between 1917 and 1918 negotiations took place with Mr. Barnes, the Pensions Minister, and three members of the British Medical Association were appointed to the Advisory Committee formed by the Ministry of Pensions. The British Hospitals Association practically adopted the policy of the British Medical Association; and in January, 1918, as the result of discussion between the Ministry of Pensions and London hospital staffs, a memorandum of arrangements was issued in which financial acknowledgement of the work done by hospital staffs for the Ministry was agreed to. The Representative Meeting in 1918 adopted the recommendation of the Council that the financial acknowledgement in the respect of discharged sailors and soldiers should be two guineas a case, or 10 per cent. of the amount paid to the institution for the maintenance and treatment of the patient. A proposal of the Council in 1919 that this remuneration should not be less than 25 per cent. of the payments to the larger hospitals, and not less than 15 per cent. of the payments to the smaller hospitals, was rejected by the Representative Meeting, which passed a resolution that when the treatment of soldiers and sailors for diseases or injuries connected with the war was undertaken at voluntary hospitals, the medical staff should be adequately remunerated. In 1920 the Council again advised that not

less than 25 per cent. of the payments to hospitals should be handed over to the staff, this time in the case of all hospitals; and on this occasion the Representative Meeting adopted the recommendation.

So far we have indicated the effect of Government assumption of responsibility for treatment upon opinion in the British Medical Association and amongst hospital staffs. But at this point another factor comes into prominence. As pointed out in the Cave report, until the year 1913 the voluntary hospitals in London were able for the most part to meet their expenditure out of their receipts. With the war came a steady increase in the cost of provisions, fuel, drugs, etc., and a growing demand for an increase in salaries and wages, so that expenditure grew faster than income. The withdrawal in 1919 of many military patients, for whom a Government grant had been received, accentuated the difficulties of the hospitals. Consequently, in 1920 the governing bodies of many of the voluntary hospitals, in searching for means to increase their income, had adopted various methods for obtaining from patients, either individually or through their societies or otherwise, contributions towards their maintenance in hospital. These contributions were the more easily forthcoming owing to the high rate of wages which had prevailed during and after the war, and the consequent disappearance of a large number of the necessitous poor.

Other and less important factors in raising the demand for staff funds were the difficulty experienced by the younger members of the staffs of hospitals in making both ends meet (especially when hospital work was coming to occupy more and more of their time), and the fact that in many districts in England representatives of the working classes had obtained seats on the governing boards of voluntary hospitals, and had promoted contributory schemes in which a definite return in the way of hospital treatment was expected as a result of these money contributions.

In consequence of these developments the Council of the British Medical Association called a conference of the honorary medical staffs of voluntary hospitals with more than 50 beds, at the house of the Royal Society of Medicine on December 21st, 1920. It was attended by 138 representatives. At this conference it was agreed that persons who were not necessitous should make contributions towards their maintenance in hospital; that paying patients, who paid more than full maintenance, should arrange their fees for treatment with their medical attendants in the hospital; and that in connexion with certain classes of patients "staff funds" should be established. Thus it was at this conference apparently that the resolution with regard to staff funds which has come to be known as the Leicester resolution was carried. The terms of this resolution are:

"That in the event of decisions being taken which would lead to patients paying in part or in whole the hospital maintenance fees, either individually or by some contributory method, or with the addition of rate aid or State aid, or by a combination of two or more of these methods, a percentage of all such payments should be passed into a fund which can be allocated in any manner which each honorary medical staff may determine."

At the Representative Meeting held in Newcastle in 1921 the Council, after calling attention to the final report of the Cave Committee appointed by the Minister of Health to inquire into the financial position of the voluntary hospitals, advised the adoption of the Leicester resolution. This was carried with the addition of a sentence excluding from the scope of the resolution those patients for whom voluntary hospitals may happen to provide accommodation as paying patients, who therefore pay more than their actual maintenance charges, and by whom fees for professional services should be payable directly to the doctor. The Representative Meeting disagreed with paragraph 50 of the final report of the Cave Committee on Staff Funds, passing the following resolution:

"That this meeting disagrees with the following paragraph 50 (pp. 31-2) of the Report of the Government Committee on Voluntary Hospitals, and maintains that the essence of the voluntary hospital system is the independent and voluntary management and that this is in no way related to the conditions of service of the medical staff:

"50. In connexion with the grants by public authorities it appears desirable to refer to the practice which obtains in some hospitals of carrying a proportion (from 10 per cent. to

20 per cent.) of these grants to a staff fund which is placed at the absolute disposal of the honorary staff. In some of these hospitals, as at St. Bartholomew's, at the Royal Infirmary, Manchester, and at the Radcliffe Infirmary, Oxford, the fund has hitherto been applied by the staff to such purposes as the purchase of expensive apparatus or books, and the support of young practitioners taking up special branches of work; but in other cases the fund has been divided among the staff. The practice is supported by the British Medical Association on the ground that patients sent by a public authority are in the position of paying patients and that in the fees paid for such patients the medical practitioner is entitled to share. On the other hand, the honorary staffs of some hospitals are unwilling to share in such a fund; and two distinguished physicians expressed the view that if the medical staffs came to be subsidized to any substantial extent 'the bottom would drop out of the voluntary system.' It should be remembered also that, although the services of the staff are honorary, they obtain a valuable return in the form of medical and surgical experience and the enhanced reputation which accrues to a member of the visiting staff of a great hospital. If the system of carrying a percentage to a staff fund is confined to cases where the full cost of maintenance and treatment is paid by or on behalf of the patient, not much objection can (we think) be taken to it; but any extension of the practice beyond those limits appears to us to endanger the future of the voluntary hospitals."

The adoption by the Representative Meeting of the Leicester resolution led the Council of the Association to call a conference of the staffs of London voluntary hospitals to discuss further action with regard to the formation of staff funds. This conference met at 429, Strand, under the chairmanship of the late Sir James Galloway, on November 16th, 1921. Eight of the large teaching hospitals were represented. The Leicester resolution was approved by 23 votes to 21. The representatives of St. Thomas's Hospital, having received no instructions, did not vote. On March 22nd, 1922, a further conference of voluntary hospital staffs in England and Wales was held at the Wigmore Hall, with Sir James Galloway as chairman. Objections to the formation of staff funds were raised by the representatives of various hospitals, both provincial and metropolitan; but the Leicester resolution was ultimately carried by 85 votes to 23.

In the meantime the Council of the Association had elaborated its hospital policy, and this was presented to the Representative Meeting at Glasgow in 1922. Considerable difference of opinion was manifested with regard to the proposals for the formation of staff funds, and an amendment was proposed in the following terms:

"That in the event of decisions being taken which would lead to patients (other than patients referred to in Sections IX (a) and (b)) paying in part or in whole the hospital charges (1) when such payments are in any part made by rate aid or State aid, and (2) where such payments in other cases are of an amount exceeding the cost of hospital maintenance and accommodation, such charges shall be considered to include payment towards maintenance and treatment, and a percentage of all such payments should be passed to a fund which is at the disposal of the honorary medical staff of that hospital."

This amendment was carried by 64 to 55; and as it was thought that the majority requisite to make it the policy of the Association could not be obtained, further discussion led to the passing of a resolution:

"That it be an instruction to the Council to reconsider the terms of the policy of the Association expressed by the A.R.M. 1921, Minute 236 (i.e., the Leicester resolution), and to report what, if any, modification may be desirable to meet any possible inequities that may arise from its operation."

In September, 1922, the Hospitals Committee considered this decision and resolved to recommend to the Council:

"That income derived from gratuitous contributions, existing assets, endowment funds, and the like, are not liable to assessment for Medical Staff Fund purposes, but all payments made for hospital benefit (other than payments made by private patients referred to in Section IX (a) and IX (b)) are in fact payments towards all the services of the hospital, whether medical or ancillary, and therefore a percentage of such payments should be passed into a fund which is at the disposal of the honorary medical staff of that hospital. Small payments of individual patients not recoverable from third parties may be assessed in a nominal percentage only as a token recognition of the policy enunciated."

On October 25th, 1922, the Council approved this recommendation, which is to be submitted to the Representative Meeting at Portsmouth in July.

To sum up the present position, the British Medical Association has elaborated a hospital policy; included in this

policy is the proposal to establish a special staff fund to be at the disposal of the medical staff of each voluntary hospital, and it has been suggested that to this fund there should be passed a percentage of all sums received from or on behalf of patients (other than private patients) towards the hospital costs. When the Representative Meeting at Glasgow declined to accept this proposition in its entirety, the question was referred back to the Council with a view to meeting inequities; and the Council has now resolved that such inequities are met by assessing small payments of individual patients in a nominal percentage only, using such assessments as a "token recognition" of the principle that all payments made for hospital benefit (other than those of private patients) are payments towards all the services of the hospital, whether medical or ancillary. It does not appear that this principle has been accepted by the majority of hospital staffs; and it is not clear that the Representative Meeting of the Association has accepted it in so many words. But it appears to be fundamental to the whole question at issue.

Passing now to the views which are held by the various parties to the controversy, it appears that at one extreme there is the whole-hearted supporter of the principle that all payments to hospitals by and for patients (other than private patients) are payments towards all the services of the hospital, medical and ancillary. Such a one holds that there is no justification for exploiting the doctor in the case of a person who is able to contribute to the hospital charges. He considers that the principle should be carried to its logical conclusion, that all such contributions should be assessed in a percentage for the staff fund, and that only necessitous persons should receive gratuitous services from the medical staff. In his view the assessing of such percentages does not, or need not, interfere with the voluntary nature of a hospital. At the other extreme is the man who desires to continue intact his gratuitous services at voluntary hospitals. He fears that by assenting to the proposition of a staff fund he will alter his status at the hospital—will become to some extent a paid servant of the institution. Moreover, he is in doubt whether his acquiescence in the proposal may not lead to the ultimate abandonment of the voluntary principle in hospital management. Between these two extremes there are many shades of opinion. Thus most members of hospital staffs probably feel that the State and the municipality have no right to expect gratuitous treatment for patients for whom they are responsible. Others adopt the same attitude towards employers, approved societies, contributory schemes, and so on. Others, again, feel that a distinction should be drawn between maintenance and treatment, and would only agree to contributions to staff funds where the payments by or for the patient exceeded the cost of maintenance.

It will have been noticed that in stating the various views on the formation of staff funds the question of the preservation of the voluntary system in hospital management arises. In the interim report of the Voluntary Hospitals Commission recently issued by the Ministry of Health the following definition of a voluntary hospital is given:

"An institution (other than an out-patient dispensary) managed by a responsible committee and wholly or mainly supported from voluntary sources (including income derived from endowments or investments), the object of which is to provide medical or surgical treatment of a curative character; an auxiliary institution (such as a convalescent home) being eligible for assistance (i.e., from the Commission) only in so far as it increases the facilities of hospitals from which it receives patients."

And in the earlier part of the paragraph containing the definition the Commission states: "We were clearly of opinion that voluntary management by a responsible committee was an essential condition." These words may be held to support the view of the British Medical Association, which maintained that the essence of the voluntary hospital system is the independent and voluntary management, and that this is not necessarily related to the conditions of service of the medical staffs. On the other hand it is to be noted that the Voluntary Hospitals Commission has not so far considered the question of medical staff funds; and its statement that a particular method of management is an essential condition does not exclude the possibility of other conditions, less essential perhaps, but yet calling for consideration. The point is one of the issues in the discussion.

## THE CAMBRIDGE SCHOOLS OF PHARMACOLOGY, BIOCHEMISTRY, AND PHYSIOLOGY.

At the invitation of Dr. W. E. Dixon, F.R.S., the Section of Therapeutics and Pharmacology of the Royal Society of Medicine paid a visit to Cambridge on Saturday, May 5th.

A party of about twenty arrived in the morning and first visited the department of pharmacology, where Dr. H. W. C. Vines gave an account of a chemical method he had devised for standardizing parathyroid extract. Dr. T. S. P. Strangeways showed a series of cultures of living tissues *in vitro*, and gave a short account of researches he was pursuing with these cultures. By the courtesy of the authorities of Emmanuel College, lunch was provided for the party in the college hall.

### *The Physiological Laboratories.*

In the afternoon the party visited the physiological laboratories, where Professor Langley demonstrated a series of sections of nervous tissues and nerves.

Mr. J. Barcroft showed the party round the section of the laboratory devoted to the study of blood gases. Mr. Barcroft and his co-workers have devoted continuous attention to this subject for many years, and it was very interesting to see the refinement and perfection of technical detail and of organization which has been attained in this work. In one room was a large oxygen chamber in which any desired tension of oxygen can be produced and maintained, and in which a man can live if necessary for weeks. Another room was organized for the analysis of the blood gases in small samples of blood, and was filled with ingenious mechanical shakers and stirrers, which obviate almost entirely the tedious and wearisome hand manipulations usually associated with this class of work.

Mr. Barcroft's technique is devised largely with the aim of measuring the blood gases, using a minimal quantity of blood. An interesting contrast was provided by Messrs. Hartridge and Roughton, who showed arrangements for handling blood by the gallon, and a simple and effective apparatus by means of which the gases could be removed completely from large volumes of blood and excessive frothing avoided.

### *The Biochemical Department.*

The party next went to the Balfour Laboratory, where Professor F. G. Hopkins showed them round the biochemical department. This department is housed in old buildings, which have been adapted to serve as laboratories, and illustrates very clearly the truth that the value of the work turned out by a department depends upon the men in it and not upon the buildings which they occupy. The building is packed with research workers, and from it has come some of the most important recent discoveries made in biochemistry. The work of Winter and Smith was naturally of particular interest to the visitors. These workers have recently shown reason to believe that the sugar in normal blood is different from the sugar occurring in diabetic blood, and are now engaged in the isolation of insulin from yeast, as mentioned in their paper published in these columns on April 28th (p. 711). This research is still in progress and promises results of the greatest importance to clinical medicine.

Professor Hopkins gave a short account of the numerous other lines of research that are being conducted in the building. These researches are largely directed towards the elucidation of problems of cell metabolism, and in particular towards determining the nature of the oxidative processes that occur in cells. A short demonstration was given of the reactions showing the presence of glutathione, the tissue catalyst recently discovered in the department.

### *The Pharmacological Department.*

The party finally returned to the pharmacological laboratory, where a demonstration was given by Mr. Goody of the action of a sulphur compound, allied in structure to mustard gas, which produced acute oedema of the lungs when injected intravenously.

Dr. O. Inchley demonstrated the action of a constant current in the passage of strychnine into rabbits, and gave a short discourse on the effects produced by ioniza-

tion, showing clearly that the electric current could drive drugs through the skin, but that as soon as they reached the underlying tissues they were taken up by the general circulation, so that the effect produced by the drug was essentially the same as that of a hypodermic injection.

Dr. M. B. R. Swann gave an account of some unpublished researches upon the action of x rays upon plain muscle, both *in vivo* and *in vitro*. This concluded a long and interesting programme and a vote of thanks was moved to Dr. W. E. Dixon by Dr. W. Langdon Brown, the president of the Section.

### *The Linacre Lecture.*

Many of the party stayed to hear Sir Archibald Garrod deliver the Linacre lecture on "Some Glimpses of the Higher Medicine." Its main thesis was that a large number of diseases were due to slight individual variations in metabolism, and that the old ill defined conception of diathesis could be replaced by the conception of chemical individuality. The whole lecture stressed the great and increasing debt that medicine owes to biochemistry, and therefore formed a singularly fitting conclusion to a day spent visiting the pharmacological and biochemical departments.

This account of the day's entertainment is of necessity largely a catalogue of events, but perhaps the most important benefit of the visit was the opportunity it gave the visitors to realize upon how large a scale and with what keenness research upon the chemical functions of the body in health and in disease is being conducted at Cambridge. There is no doubt that work upon these lines will serve in the future as the foundation of a new and greater science of medicine.

## THE STUDY OF FATIGUE IN INDUSTRIES.

THE publication of the third annual report<sup>1</sup> of the Industrial Fatigue Research Board was briefly mentioned in our columns last week (p. 779), and attention was called to the objects which guide the activities of the Industrial Fatigue Research Board. The report covers a period of fifteen months and outlines the results obtained up to the end of 1922. The serious industrial depression, which characterized the whole of the period under review, seriously handicapped the work of the Board, partly because the industrial atmosphere was unfavourable for the introduction of novel ideas and methods, and partly because employers' and workmen's organizations have been so fully engaged with urgent economic problems that they had little opportunity of giving the necessary consideration to any schemes submitted. Moreover, the variations in industrial conditions caused by short and irregular hours have introduced disturbing factors which have notably affected the progress of some parts of the work. On the other hand, that part of the Board's work which is unaffected by conditions of trade, in particular laboratory research, has actually expanded and definite results have already been secured which may eventually have an important bearing on industrial occupations.

### *Investigations and Researches.*

The Board has aimed at the simultaneous prosecution of two separate lines of investigation—namely, research on fundamental points conducted in the laboratory, and inquiry based on observation of actual working conditions conducted in the factory. The former method may be said to show the effect of some known cause, whilst the latter suggests the cause of some known effect. Although at first the Board adopted certain selected industries as the field for investigations, it has recently taken as its objective the study of certain general subjects, not confined to any one industry but of common interest to all, following up each subject along lines which experience showed to be most promising and dealing with it both by field investigation and by laboratory research.

### *General Investigations.*

Grouped under this heading are reported investigations on the optimum length of spell, accident causation, machine design, and sickness incidence and mortality. Widely divergent practice exists in different industries in regard to the

<sup>1</sup> Third Annual Report of the Industrial Fatigue Research Board. Medical Research Council. 1923. (2s. net.)

division of the working day, and the Board has decided to start an extensive investigation to ascertain the best length of spell, and the best arrangement of rest pauses, for industrial occupations of different types—from the heaviest manual labour to monotonous work involving mental rather than muscular effort.

The study of the personal factor in accident causation is undoubtedly of great importance in connexion with prevention, and the Board is conducting an inquiry by statistical and psychological methods with the object of determining—

1. How far a characteristic ratio between notifiable accidents and accidents of all kinds exists for different selected occupations.
2. The correlation of accident incidence with experience, age, and sex.
3. The extent to which special susceptibility to accident exists.
4. The primary causes of such susceptibility.

A report recently published by the Board deals with accident causation from its personal aspect; it embodies the results of two investigations—one on the relation of temperature, etc., to accident incidence, and the other on the relation of accuracy of movement to speed and duration of work.

In the design of machinery and plant full consideration is not always given to the requirements of the prospective operator. Ease of working is one of the first essentials to be taken into account in the manufacture of such articles as typewriters and motor cars, but often, where the necessity is less obvious, the manipulative side of design seems to have been somewhat overlooked in favour of the strictly mechanical side, and the Board is now considering the initiation "of a rather close inquiry into the question of design in the case of certain types of machine, in order to ascertain whether any principles can be evolved indicating the proper relationship of machine to operator."

Under the supervision of the Committee on Industrial Health Statistics an inquiry has been begun into the relative incidence of mortality, particularly mortality from phthisis, upon the residents in rural districts, and members of the same families, who have migrated to industrial towns and are engaged in particular occupations. This is being carried out at present in the diocese of Chelmsford.

#### *Industrial Investigations.*

On the advice of the Home Office the Board has made some investigations into the cotton trade, limiting its inquiry in the first instance to the weaving section; some of the results have already been published. The principal inferences which may be drawn from these researches are summarized in the report as follows:

- "1. The productive efficiency in cotton weaving is both high and uniform, though differences naturally exist as between the different classes of cloth manufactured.
- "2. Short time tends to have a depressing effect upon productive efficiency.
- "3. During the pre-breakfast spell, in a two-break day, the productive efficiency is about 2 per cent. lower than during the other two spells.
- "4. The reaction of the worker to his working conditions is masked by the predominance of the mechanical factor. When this is eliminated by calculation his working capacity is seen to undergo a gradual decrease, both throughout the day and throughout the week.
- "5. The atmospheric conditions in humid cotton and weaving sheds are sometimes such as to involve working under physiological disadvantage. This is shown by the fact that above a certain limit of wet-bulb temperature the efficiency tends to fall, notwithstanding the more favourable effect on the yarn itself of the higher temperature and humidity. The cooling power of the air in humid sheds appears to be abnormally low, especially during summer, and experiments in the best method of overcoming this are very desirable.
- "6. Efficiency often tends to fall under a system of artificial lighting as compared with daylight, the reduction varying in amount from 11 to 5 per cent. according to the fineness of the work involved.
- "7. The initial rise and final fall in efficiency discernible in the daily work curves are not due (as is sometimes alleged) to extraneous causes, such as lateness in starting, etc., but are of subjective origin, and represent a real quickening up and slowing down.

"8. Productive efficiency in weaving is more dependent upon physical factors, such as variations in the yarn, quality of the size used, etc., than upon the variations in working capacity on the part of the operative."

#### *Pottery Industry.*

In 1920 the Board accepted an invitation from the National Council of the Pottery Industry to participate in an inquiry dealing with the construction and ventilation of drying stoves in potters' shops: the results are chiefly of technical interest, suggestions being made for preventing or reducing the escape of hot air, and on the relative importance of temperature and ventilation in the drying of ware.

#### *Laundry Industry.*

The results obtained by the study of the laundry industry reveal the facts that the atmospheric conditions in laundries compare unfavourably as regards temperature and cooling power with other industries investigated; the interpolation of short rest pauses into spells of moderate length appears to have a beneficial effect; there appears to be a lowering of working capacity in the afternoon compared with the morning, and this effect becomes more pronounced during periods when a ten-hour day is substituted for a nine-hour day; there is no evidence that laundry work, when conducted under reasonably good conditions, is detrimental to health.

Investigations are at present being carried out in the glass industry, latch and lock industry, and post office work.

#### *Researches.*

In a series of researches on the rate of recovery after exercise, Mr. H. Lupton has shown that in the case of horizontal walking and running below a certain speed the oxygen consumption increases approximately as the square of the speed; above this any increase in speed is not accompanied by an increase in oxygen consumption, the limiting rate of oxygen consumption being probably determined by the maximum capacity of the lungs and heart to supply oxygen to the tissues. On taking muscular exercise the body "goes into debt" for oxygen to an extent depending on the severity of the exercise, and most of the deficit is recovered within a few minutes of the cessation of the exercise.

"At the beginning of exercise an oxygen deficit is set up, and this is maintained until the recovery period which immediately follows cessation of the exercise. For rates of energy expenditure below the limit set by the capacity of lungs and heart, the total excess oxygen during recovery is equal to this deficit produced at the beginning of the exercise, such deficit increasing with the speed but remaining constant for any given speed, however prolonged the exercise. Hence such exercise from the point of view of the muscular machine might be kept up indefinitely. For rates of working beyond the limit set by the capacity of lungs and heart the deficit of oxygen increases with the time. In other words, lactic acid accumulates until exhaustion ensues. The limiting speed varies with the individual, being in the neighbourhood of seven miles an hour for horizontal running."

Tests for physical efficiency carried out at Guy's Hospital have shown that the "pulse ratio" (that is, the ratio between the pulse rate for the two minutes following exercise and the pulse rate at rest) is a good indication of physical fitness in the case of mild muscular exercise, but that this does not hold good for more severe exercise, such as running a mile.

Other researches being carried out by the Board include the study of the effect of rest-pauses and change of posture, the effect of atmospheric conditions, muscular control, motor capacity, accuracy of movement, monotony, coloured inks and papers, and the legibility of type.

Part II of the report contains five personal contributions from investigators working for the Industrial Fatigue Research Board. Mr. E. Farmer discusses "Some considerations concerning technique." Miss May Smith writes on "The use of the sample in investigation," and Mr. S. Wyatt contributes "Some observations on industrial conditions, with special reference to cotton weaving." Dr. Vernon is the author of two articles, one on "Atmospheric conditions and industrial efficiency," and another dealing with "Future investigations in the pottery industry." Mr. H. C. Weston contributes a note on machine design in relation to the operative.

## British Medical Journal.

SATURDAY, MAY 12TH, 1923.

### MEDICAL EDUCATION IN THE MELTING-POT.

SIR GEORGE NEWMAN has done a public service in issuing at the present juncture a memorandum on recent advances in medical education in England. A summary of his essay has been given in our last two issues (April 28th, p. 729, and May 5th, p. 771).

The rapidity with which the present conception of medical education has been evolved may be considered remarkable. For the first questionings whether the system of medical education in England was keeping abreast of the times we need not, for the present purposes, go back further than to the final report, published in 1913, of the Royal Commission on University Education in London, which discussed some questions and principles which are not peculiar to London. The Commission, in summarizing its conclusions, said: "The complex nature of the science of medicine and its dependence for assistance upon other branches of science necessitate co-operation, and the special organization of a professorial department, in order to enable the professor to carry on research successfully, and also to give scientific instruction in the subject. The kind of hospital organization known as the 'hospital unit' appears to us well fitted for attaining this end. It consists of:—a professor with the control of wards; an out-patient department; assistants nominated by the professor with a view to complementing his own knowledge and affording him the special assistance he requires to carry on research in the direction in which he is interested; and, finally, laboratory accommodation in close proximity to the wards, not only for the service of the wards, and the examinations and procedures connected with the diagnosis and treatment of the cases, but also for the purposes of research."

The Royal Commission recognized that there would be difficulties in the way of appointing a sufficient number of professors, but thought that some of the work might be done by the assistants to the professors and that some of the senior assistants would probably be exceedingly well qualified for this purpose. It added that this plan would give the opportunity of calling in the more experienced assistance and co-operation of members of the profession in active practice, and that this would be of advantage both to them and to the students. The financial difficulty was smoothed when Parliament agreed to make a substantial increase in the annual grant to universities and institutions of university rank. The University Grants Committee, appointed in 1919 to administer the grant, gave attention, among other subjects, to the question of clinical units, and grants for this purpose have been made.

The General Medical Council was brought into the matter of reform in medical education rather by a side wind. At its session in May, 1918, it instructed its Education Committee—in terms of a resolution submitted by Dr. J. C. McVail and Professor Elliot Smith—to inquire and report on the question whether the teaching of preventive medicine ought not to be further systematized. Sir George Newman's

first memorandum was issued at the end of July, 1918, and during the following winter the conclusions of a series of discussions at the Edinburgh Pathological Club were formulated by a Committee, of which Professor Lorrain Smith was chairman, and published in the *Edinburgh Medical Journal*. The Education Committee of the General Medical Council prepared an elaborate set of questions which the Council approved and sent to the medical schools; the questions were of such a nature as to foreshadow a policy the chief feature of which would be that the whole medical course in the schools should be permeated by the spirit and principles of prevention, beginning even with the preliminary sciences and continuing through the clinical courses and into the final examinations. The questions were numerous and searching, and when the replies received from the schools were considered it became obvious that the time had arrived for reviewing and revising the whole medical curriculum. This has now been done, and the new curriculum has been in force since the beginning of the present year.

But Sir George Newman's memorandum is much more than an exposition of the Medical Council's new scheme. He emphasizes clearly and vigorously his own views on the outstanding requirements of medical education. In the recent literature of local and central administration the term "co-ordination" is often to be found, and has been used to express the desire for effective and economical relations between old and new spheres of work. Co-ordination does not mean amalgamation, but harmonious and mutually helpful co-operation, so that there shall be neither hiatus nor overlapping. Sir George Newman, however, says little about co-ordination but a deal about integration, by which we take him to mean something more than co-ordination. The dictionary meaning of integrate is "to render entire or complete; to put or bring together (parts or elements) so as to form one whole; to combine into a whole." A very fine ideal as applied to medicine in all its aspects—prevention, treatment, and scientific research; an ideal, indeed, difficult of attainment, but to be attained if we are convinced of its necessity.

Many will look first for what Sir George Newman has to say about the clinical unit, of which so much has been heard since the London Royal Commission reported ten years ago. It is fully discussed in two chapters, and there is logical significance in the order, the one on the chief needs of clinical study, and the other on university clinics (clinical units). All will agree that the needs of clinical study as they develop must be met, and that the manner of meeting them must be such as to bring their teaching to a university standard, but the clinical unit is only a means to an end; the exact plan by which the end is attained is a minor matter provided it be elastic enough to adapt itself to varying needs of the time, present and future, and of place. We want new methods, but not a violent wrench with the past; we must seek to retain all the good in the old system of medical education in Great Britain, and to strengthen it where—especially in England—changing conditions have discovered weaknesses in the machinery. This doctrine Sir George Newman develops at length, with many historical references, apt quotations, and plans for the future, the whole pervaded with a sublimated sort of common sense.

Thus while he writes "one fact is both certain and universal—the claims of clinical teaching and the need for adequate equipment for such teaching have advanced in such a way, and to such a degree, as to make

reorganization absolutely necessary," he goes on to point out that "such reorganization may well take different forms, but it must provide opportunity for effective teaching in the clinical as in the intermediate subjects." The university clinic has two purposes—the provision of education of university standard in the clinical subjects for all students, and the advancement of learning. In developing the second point Sir George Newman writes: "It is the goal of medicine which here must be striven for, it is the sum total of knowledge applicable to the betterment of man's physical estate which must be synthesized. The ordinary dispensary treats the case; the University Clinic does the same, but out of the case it should draw a liberal education and provide for the sounder and fuller treatment of all similar patients, for it should so think and work as both to train the student and extend the frontiers of knowledge and of life." Then he comes to the issue presented by the practical application of the doctrine thus enunciated, and, we believe, generally accepted. "Much expenditure and educational attention have been devoted to the sciences of anatomy and physiology, but the clinical subjects have not, until recently, received their due. All too often they have been left to the chances of incidental teaching by an honorary hospital staff, unable to devote itself principally to teaching and research. Incidental teaching of clinical subjects cannot uniformly be of university standard."

As to the details of the plan along which the university clinic is to work he keeps an open mind. There was an attempt, made by well-meaning persons unacquainted with the history of the system of medical education which has grown up in this country during the last hundred years or more, to assert that it was all wrong, that we must have a clean cut, and start afresh on a plan they prescribed. Sir George Newman has freed himself from doctrinairism, if ever he was affected by it, and frankly confesses that the aim may be reached in several different ways, though he adds a caveat to the effect that "longer experience may modify opinion, and especially so when the existing clinics have trained competent leaders for whole-time posts." Nevertheless he sees and frankly sets out the defects of the whole-time plan as applied to the clinical subjects; some of them may be diminished, as the opinion just quoted suggests, but others are inherent. It has never been strictly carried out in Germany, Austria, Switzerland, or France, and is not spreading in America, from which it came to us. Another plan which is working there in some places provides the whole-time professor with special wards and consultation rooms, where he treats private patients, the fees being paid to him direct or to the governing board of the hospital, which has an equitable arrangement with him. Another method of solving the practical problem is that by which a part-time professor or teacher has whole-time assistants, to whom some of the professorial duties are assigned; the practical application of this method at Leeds was described in our columns last year.<sup>1</sup> Yet another method permits the clinical professor to undertake outside private practice to an extent which will not interfere with his duties as head of the university clinic. "Such restriction may take various forms, either on a time basis or in respect of the character of the practice undertaken. An example is the Regius Professor of Clinical Surgery at Edinburgh." Sir George Newman's view is that of the four types of solution the English medical schools will be most likely to favour the last here mentioned. The real objective is

to find "the best method of creating a team of clinicians who are also laboratory workers, in a unit, under the leadership of a professor who has control of beds, laboratories and out-patient department, with adequate provision as regards time, equipment, and teaching ability, in order that the clinical education of the student may be directed along lines that will produce the best treatment for patients and the advance of knowledge." We come round, therefore, to something very like the French plan when that is worked by the best men under the best conditions.

The essay is the primary concern of those engaged in medical education or in any way responsible for it, but it can be read with interest by the practitioner as an exposition of the trend of present-day thought, and will be of value to the newly entered student by giving a broad conception of the meaning of the curriculum, of why the subjects are linked together in a particular order, of the bearing of every one of them on all the rest, and of the ultimate objective of the whole, which is not merely to pass the examination required for a registrable qualification—a condition unfortunately imperative in this imperfect world—but to learn how to prevent and cure disease throughout his professional life. To that end he will continue to study after graduation, when he will no longer be pestered by examinations and examiners, but will have for his sole aim the understanding of the problems of health and disease, and the application of his knowledge and experience to the welfare of those who commit themselves to his care.

## INDUSTRIAL FATIGUE.

EVOLUTIONARY adaptation of man to modern industrial conditions can hardly be expected to go further without damage to the race, and the imperative necessity of adapting the machine and the environment to the man is beginning to be better understood. So specialized and standardized have the processes in many trades become that the workers perform exactly the same actions in exactly the same way hour after hour and day after day, carrying out a routine whilst breathing often a moist or dusty atmosphere in an ugly building reverberating with the ceaseless clank of machinery. Increase of production has been the chief aim of our industrial age, and to obtain the maximum increase with the minimum expenditure of money the man of to-day has been trained to a degree of monotonous mechanical efficiency which rivals that of the complex machines he tends.

The amelioration of the artificial surroundings of the factory or workshop promising greater comfort to the worker, and improvement in the design of machinery to eliminate causes of accidents and to diminish risks to health, are objects which, from hygienic and philanthropic motives, have been the care of public health legislation. They are now being studied by employers of labour with a view, as is assumed, to increased production—a motive which occasionally arouses suspicion in the powerful organizations of the workmen, who fear that it may be only a fresh means of exploitation.

This atmosphere of mistrust is probably quite unwarranted, since adaptation of the machine to the individual, if successfully achieved, will benefit both employers and workmen, and the establishment of the Industrial Fatigue Research Board, whose objects are entirely disinterested and whose aims are purely scientific, has been a move in the right direction. It is an impartial authority in which both parties may have confidence. A detailed note on the Board's third annual report will be found at page 819, but we may here pick

<sup>1</sup> BRITISH MEDICAL JOURNAL, 1922, vol. 1, p. 21 (general principles) and p. 834 (detailed plan).

on three examples of the services it is capable of rendering. In the weaving of certain kinds of cotton cloth moisture is injected into the air of the room. Objection has been taken to this practice, which is trying to the workpeople, especially during the hot summer months, and several committees of inquiry have sat. Evidence has been given to them to the effect that work of the type of weaving is carried out under disadvantageous conditions when the wet-bulb temperature in the sheds exceeds a limit variously given as 70° or 75° F. At temperatures approximating to these the body temperature of a worker tends to rise as work proceeds, and two recent reports to the Board have shown that "in cotton weaving the time taken by the weaver to deal with each breakage increases, within limits, as the wet-bulb temperature rises, and that in the kindred process of fine linen weaving efficiency falls to a marked degree when the wet-bulb temperature reaches 73° F." Thus amelioration of conditions in this respect is in the interest of the industry. Again, it has been found that in the weaving both of silk and fine linen the effect of even a good system of artificial lighting, as compared with natural lighting, is to reduce productive efficiency by about 10 per cent. The causes of accidents, broadly considered, form another matter of great interest, and some controversy has arisen as to the relative importance of fatigue and speed of work as factors in accident incidence. Dr. Vernon's researches indicate that speed of work is the more important factor, since the output curve and the curve giving hourly accident incidence usually correspond closely; this view is confirmed by the fact that no increase in accidents is observed at the end of a spell of work, when fatigue would naturally be expected to manifest itself.

Much may be expected in the future from a study of the design of machinery in relation to the convenience of the operative. The shape, size, and position of levers and hand-wheels, and the power required to operate them; the height of the working plane, the area which has to be kept under observation, the extent to which the operative may be required to reach both in the horizontal and vertical directions, and the number of controls, together with the order in which they are managed—all these are problems demanding investigation. Adaptation of the machine to the individual will result both in increased production and greater comfort for the worker.

### NURSES' REGISTRATION.

THE Nurses' Registration Act of November 1st, 1919, laid upon the General Nursing Council the duties of forming a Register, regulating the conditions for admission thereto of such nurses as were already in practice, and of prescribing the training and regulating the examinations which should be conditions of admission for the future. Parliament gave no indications as to the admission of nurses already in practice, termed in the Act "existing nurses," except that they should have been in bona fide practice for at least three years before November 1st, 1919, "under conditions which appear to the Council to be satisfactory for the purposes of this provision and have adequate knowledge and experience."

The first Council was an appointed body. It was charged to form a scheme for the election of sixteen members on to the second Council. The second Council, formed of sixteen elected and nine appointed members, came into existence this year.

In admitting nurses to the Register the Council has required hitherto that all general nurses should have

undergone at least one year's training in some general hospital. Under this term have been included small cottage hospitals. If training was to be required the conditions could hardly have been more lenient. But about a year ago complaint was made that competent nurses were being excluded by this requirement. The Council made several attempts to satisfy this complaint, but it is obliged by the Act to consult with the Nursing Councils of Scotland and Ireland, as well as to obtain the approval of the Minister. Each proposal made by the Council up to the present was blocked either by one or the other of these authorities. At present a proposed rule of the Council that nurses in practice before 1900—after which date hospital training became the acknowledged custom—should be admitted on evidence of competence alone, is before the Minister, and if approved by him will lie on the table of the House. It is to this rule that the Committee of Medical Members of Parliament is reported to object. Their intention, it has been announced, is to propose an amendment admitting all nurses who have been three years in practice before November 1st, 1919, without requiring any hospital training, and substituting therefor testimonials of competence and an examination by the Council. It seems to us somewhat doubtful whether the latter would be made satisfactory.

The Nursing Council has also been engaged in drawing up regulations for the future. Under this head are included the approval of hospitals for training schools—obviously a difficult and invidious task—the drawing up of syllabuses relative to training and examination of every branch of nursing, and the arrangements and regulations necessary for holding simultaneous quarterly examinations at various centres throughout England and Wales. This latter is a complicated piece of business.

The scheme which was adopted for the election of the existing Council was subjected to certain criticisms in the House of Commons, and on March 14th Major Barnett proposed a large number of amendments, although only one of them raised any point of principle. The scheme for election provided that six of the eleven representatives of the registered nurses should be past or present matrons. Major Barnett's suggestion was that the registered nurses should elect eleven nurses to represent them, and that they might or might not be matrons. This, he said, followed a precedent set in Scotland. All the amendments were passed by the Minister of Health to the Nursing Council for consideration and report. It must be remembered that this Council has two main functions—the regulation of the education of nurses and the maintenance of a satisfactory register. In view of the importance of the functions of the Council in relation to education it may be doubted whether it would be justifiable to leave its constitution wholly to the chances of an open vote.

The first volume of the Register, issued as ordered by the Act as soon as possible after July 21st, 1922, contained 6,000 names. By November 24th the electorate had risen to 12,000, and about 3,000 more have been added since then. It seems, therefore, as if nurses were registering in good numbers.

### THREE PIONEERS.

THE grave in which Sir Shirley Murphy was laid to rest last week in Brookwood Cemetery is within a few yards of those of two men to whom he was bound by close ties of friendship and who were equally eminent with him in the sphere of public health—Sir George Buchanan and Sir William Henry Power. It is said that the burial-place of Sir Shirley

Murphy was selected by Lady Murphy so that he might rest near his old friends. It was a fine thought. When these three were in their prime the number of medical men devoted to the practice of sanitary science and preventive medicine was a mere fraction of the total so occupied in the present day. Two of the three were at the head of the public health service in England, while the third was in a similar position for the greatest municipality of the British Empire. Buchanan—eager, a man of action, fretting against the bars of the prison in which, even when he had attained the highest office open to him, a man who gave himself to public health was then confined. Power—reserved, taciturn, contemplative with patience to wait on events, the progress of which he seemed to believe could not be hurried, only directed. Shirley Murphy—genial, ready to give himself freely, pouring out facts, opinions, questions, which his retentive memory had stored or his rapid mind was formulating. He had a great opportunity; the consciousness that he had risen to it made happy the mellow years of his retirement. These three now sleep their long sleep together under the shade of the firs in the great cemetery which retains more of nature and owes less to art than the long roadways of well-trimmed plots which compose the ordinary burying places of great urban populations.

#### THE ROYAL ACADEMY.

AN exhibition of pictures, such as that at the Royal Academy of Arts, may offer matter of interest from a medical point of view because it contains portraits of medical men and women; or from time to time because a medical man exhibits a work of art found worthy of acceptance by the hanging committee; or because—and this is not very infrequent—an artist has introduced into his picture, consciously or unconsciously, the representation of some physical abnormality or disease. In any case the artist is commonly concerned with two subjects upon which medical men can claim some measure of expert knowledge—namely, anatomy and colour. This year's exhibition at Burlington House does not appear to contain many works by doctors; but we noticed a water-colour painting, "In a Chelsea Studio" (No. 768), by Dr. Cecil W. Pilcher. In each of the other directions, however, there is more matter for comment. In Gallery I there is a very good portrait (No. 31) of Sir Malcolm Morris in a characteristic attitude, by Mr. Walter W. Russell, A.R.A. The portrait (No. 129) of Miss Aldrich-Blake, M.S., M.D., is perhaps the best by Sir William Orpen in this year's exhibition. Mr. Edwin A. Ward exhibits a somewhat ordinary painting (No. 230) of Sir William Church, which is, however, a very good likeness. The charcoal drawing (No. 1027) of Sir Alfred Rice-Oxley, the ex-Mayor of Kensington, by Mrs. L. Anning Bell, is of average merit, but a poor likeness. Amongst the sculpture there is a bust (No. 1361) of Professor D. Greig, F.R.C.S., by Mr. George D. Macdougald, a model (No. 1365) for the obverse of the Lister memorial medal, by Mr. Charles L. Hartwell, A.R.A., and a medallion (No. 1370) of Dr. William Harvey, by the same sculptor. Sir George Frampton exhibits a bronze bust (No. 1465) of Sir John Bland-Sutton. With regard to physical abnormalities, the attention of the medical visitor will be caught very early by the unpleasant corpse-like flesh colour of the two figures in Mr. Glyn Philpot's "Little Dancer" (No. 15). Why two apparently living beings should be represented with such complexions is an enigma. Against such a travesty may be set the flesh painting in "The Entombment" (No. 2), a picture in the primitive style, in which Mr. David Poynter has attempted with success to reproduce a corpse-like colour in the dead Christ—an unusual effect. Mr. Maurice Greiffenhagen's diploma work, entitled "The Message" (No. 454), raises the question whether the painter really admires enlarged thyroids, or whether his representation of such an abnormality is due to the influence of Rossetti. There is another

picture in which the abnormality is also to be detected. The examination of an exhibition of pictures from the stand-points of anatomy and colour might be a fascinating pursuit. We have heard it said that art schools would do well to confine their attention mainly to these subjects, and to leave art to be evolved by the artist. Certainly the exhibition does not want in examples of the need for closer study both in anatomy and in colour. Thus the greens in many of the landscapes and other pictures are suggestive of defect in colour vision. Take for example "Before the Ruined Abbey" (No. 259), with its spinach-like grass, by Mr. Sydney Lee, A.R.A., or "The Birth of a River" (No. 666), by the same artist, depicting, apparently, a glacier of lifeless green surmounted by a cap of dirty snow; and compare these with the greens which have accomplished their purpose in Mr. Algernon Talmage's "Morning After Rain" (No. 140) and Mr. Edward Buttar's "Wiltshire Downs" (No. 234). In No. 564 Mr. William T. Wood combines astonishing greens with trees in which the foliage resembles the painted shavings used in toy farmyards, and the wood is impossible. In "The Sisters" (No. 258), by Mr. W. G. de Glehn, A.R.A. elect, the anatomy of the neck and shoulders of the sister in pink is defective, and the suprasternal notch resembles a pit. In the background of Miss Ethel Walker's "The Invocation" (No. 627) there is a row of figures, of which that on the extreme right shows marked deformity of the hip. It is difficult to believe that in the pursuit of "line" in drawing greater satisfaction is to be derived from deformity than from health. "Tilty Church" (No. 137), by Mr. George Clausen, R.A., is defaced by a cloud with the anatomy of a bolster. The so-called pictures of the year, such as Mr. Wyllie's "Port of London" (No. 213) and Sir William Orpen's strange picture, which to many spectators is merely horrible, "To the Unknown British Soldier in France" (No. 190), present no particular medical interest. Mr. Edward Chappell's "Over the Hills and Far Away" (No. 267) and Miss Barbara Shiffner's "With 'The Grove'" (No. 668) are amusing because of the yellow carpet of sunlight spread out for a herd of cows in the one case, and the numerous green carpets for various patches of animals in the other; but that our criticism may end on a note of praise we would call attention to Mr. L. Campbell Taylor's "Priscilla" (No. 489), a work in the older Dutch spirit, to "Mischief" (No. 637), by Miss Helen Mackenzie, which is firm and good, and to the "Lady and Gentleman" (No. 646) by Mr. Alfred R. Thompson.

#### THE ANTIRABIC INSTITUTE IN BAGDAD.

AT a meeting of the Section of Tropical Diseases and Parasitology of the Royal Society of Medicine on Monday, Lieut.-Colonel A. E. Hamerton described the work of the antirabic institute at Bagdad. He said that in the tropics it had been usual to establish antirabic institutes in the temperate climate of hill stations, often far removed from the endemic areas of the disease and the centres of population, but it was often necessary to treat rabies on the plains where torrid heat prevailed. The use of carbolized vaccine was, he believed, the best method; it had stood the test of many independent investigations. The standardized glycerinated vaccine of Phillips, as used in the United States, seemed ideal for non-tropical climates, but apart from the difficulty of obtaining pure glycerin in the dusty atmosphere of a Mesopotamian town, contact with glycerin under these conditions rapidly killed the virus and presumably affected the vaccine. Rabies in dogs and hydrophobia in man had been recognized by medical practitioners in Bagdad long before the British occupation, and early in the war a good many cases of canine rabies were detected by the members of the army medical and veterinary services in Iraq, and the men who had been bitten were sent for antirabic treatment to the hill station at Kasauli. As the army, with its following of pet dogs, increased, and it became

known that a dog bite, real or spurious, meant the transfer of the victim from the infernal regions of Iraq to the delectable mountains of Hindustan, there seemed to be some likelihood that the forces would be seriously depleted. There was no doubt a good deal of malingering, but cases of hydrophobia had occurred, and it was not considered safe to disregard any instance of reputed dog bite. During 1919 a remarkable series of cases of hydrophobia occurred in a refugee camp near Bagdad. A rabid jackal attacked 46 prisoners; 28 of these were sent to Kasauli, but the journey was long and five of them died; of those not sent eleven died of hydrophobia in the army hospital. An antirabic institute was established in Bagdad by the military authorities, and the good result of the early vaccine treatment thus made possible was exemplified in some well authenticated cases. An Arab sheikh and his daughter, who had been bitten by a wolf, attended the laboratory at Bagdad and received treatment; eight other persons who were bitten at the same time refused to attend. Four months later the sheikh and his daughter were alive and quite well, while all the other persons had developed hydrophobia and had died. It was impossible to stamp out rabies in a tropical country because jackals, wolves, and, in East Africa, hyenas provided a natural reservoir for the virus. The first cases which occurred in a district should be biologically proved, and if the attack was unquestionably rabies, then more cases were to be expected, and due precautions should be enforced. As the preparation of a fixed virus was tedious and expensive it was convenient to obtain the strain from one of the Pasteur institutes already established, but the virus was exceedingly delicate, and during transit in a hot climate might be killed. In Bagdad it was necessary to send the virus from Kasauli in live rabbits which were successively inoculated. During the period of intense heat the virus seemed to lose its strength, and the animal died, not on the ninth or tenth day after inoculation, but on the twelfth or thirteenth. Each patient treated at Bagdad received a dose of 5 c.cm. of the vaccine over a period of fourteen days; the dose was given intracutaneously rather than subcutaneously. The needle was sterilized in hot oil between the inoculation of each patient. At the conclusion of the course the patient was given a stamped addressed postcard and requested to inform the director of the institute of the state of his health three months later. During 1921 the carbolyzed vaccine was used for 137 people in Bagdad, and down to May, 1922, when Colonel Hamerton left Iraq, no case of hydrophobia nor any unpleasant after-effects had occurred among those treated. The work of the institute had been continued by the civil medical administration, and only one case of hydrophobia had been reported among those who had come for treatment, a man who refused to continue the course, and received only four inoculations instead of fourteen. The cost of an antirabic institute in the tropics, if there was a well equipped laboratory already established for general bacteriological work, was trifling. The initial cost of instruments and of rabbits and rabbit hutches was from 1,100 to 1,200 rupees, and the recurring expenditure, chiefly remuneration of additional staff, 100 rupees a month.

#### THE ASSOCIATION OF PUBLIC VACCINATORS.

THE annual meeting of the Association of Public Vaccinators of England and Wales this year was an occasion of special interest, because it marked the twenty-fifth year of its existence. The activities and usefulness of the Association during these years were indicated in a summary of its history circulated among the members with the annual report. Dr. A. E. Cope, honorary secretary and treasurer, and a former president, gave an address on a quarter of a century of vaccination and its lessons. He referred to the

great value of the work of Dr. S. Monckton Copeman, as outlined in his Milroy lectures delivered in 1898—the year of the birth of the Association of Public Vaccinators. Dr. Cope dealt with the histology of small-pox and cow-pox, and observed that the essential difference appeared to be that in small-pox the amoeboid body found in both entered on a sexual phase and invaded the cell nucleus. The country had been remarkably free from small-pox during the past twenty-five years, but the disease had by no means disappeared. Small-pox had assumed different types, attributable to variations in the source of infection. In the epidemic of 1901-2 the London visitation was severe in type, having been imported from the East; in the provinces the strain was mild and came from America. Standardized calf lymph was now available in unlimited supplies, thanks to the excellent work done at the National Vaccine Establishment. There should be uniformity in the technique of vaccination, and parents should be instructed definitely regarding the after-care of the child. Dr. F. W. Brookes of Lambeth was in the chair, and it was unanimously resolved to invite Dr. A. G. Wells, one of the oldest members of the Council and honorary auditor of the Association, to become president for the ensuing year, but the meeting heard with regret that Dr. Wells was unable to accept the honour. Thereupon Dr. Brookes consented to serve for another year. He was in the chair at the annual dinner, at which, after the loyal toast and that of the Association had been duly honoured, Dr. Arthur Drury proposed the health of the visitors. The Association, he said, had always been happy in the choice of guests, and that evening was specially so. Dr. McVail's classic *Vaccination Indicated* had been an inspiration, and had provided the speaker with much ammunition during the twenty-five years in which he had been actively engaged in the defence of vaccination. The valuable researches of Dr. S. Monckton Copeman and his processes for the production and storage of glycerinated calf lymph had entirely changed the work of public vaccinators and rendered it more satisfactory. They had with them also that evening Dr. W. McConnel Wanklyn, whose work in connexion with small-pox and whose publications were well known. To Dr. C. Courtenay Lord (British Medical Association), Dr. James Neal (Medical Defence Union), Dr. Horner (*British Medical Journal*), and Dr. Pinkerton (*Lancet*) Dr. Drury extended a hearty welcome on behalf of the Association. In responding to the toast, Dr. J. McVail said that there was present a greater personification of knowledge of the art of vaccination than could be found in any part of the globe. The science of vaccination was personified in Dr. S. Monckton Copeman. He regarded it as a duty of the Association to instruct public vaccinators, and indeed the whole profession, in regard to the detail of vaccination. Small-pox always taught the lessons of vaccination without any equivocation. There was now more emergency vaccination and more vaccination of adults, and as the circumstances were not the same as with infants, every endeavour should be made to prevent the occurrence of "bad arms." A committee should produce a report of all the difficulties encountered. A single "bad" case was advertised by those who decried vaccination. Many years ago the British Medical Association issued a pamphlet on vaccination; it might be revised and brought up to date. He congratulated the Association on having the services of Dr. Drury to deal with the controversial aspect; if there was one man in the country who could bowl over the antivaccinator in controversy it was he. Dr. McVail went on to maintain that there had never been compulsion in this country. The law had been weakened, and it was therefore more imperatively necessary to educate the public. Dr. Copeman, who also replied, recounted some amusing experiences in a racy speech. He urged members of the Association to visit the National Vaccine Establishment. No fewer than eleven millions of tubes of glycerinated calf lymph were issued

## WORK OF THE FRIENDS' RELIEF COMMITTEE.

during the war. He concluded with some practical hints concerning the vaccination of adults. The health of "The President" was proposed by Dr. E. Climson Greenwood (first president of the Association), who met with a hearty reception, and duly acknowledged.

## THE WORK OF THE FRIENDS' RELIEF COMMITTEE.

The ninth report of the Friends' Emergency and War Victims' Relief Committee describes its work in France, Russia, Austria, and Poland during the year ended March 31st, 1923. In France the emergency maternity hospital established at Châlons-sur-Marne in December, 1914, has been replaced by a permanent building given by English and American Friends with the aid of some French donations; it has been handed over to a local committee to carry on, and is intended to serve as a memorial of the work of the Friends for France. Two ante-natal consultations and two consultations for infants are held weekly. As to Russia, it is hoped that it will prove possible to discontinue the famine relief work immediately after the next harvest. The deplorable conditions existing in the district of Buzuluk were described in the report for last year. The population cared for then was about 454,000; it had been reduced by last summer to about 336,000, "or, in other words, in an area roughly the size of Yorkshire and Lancashire, every third person had died." Before the last harvest about 257,000 people were being fed; at the harvest the number dropped to 65,000; later on it rose again to 103,000, and would, it was anticipated, increase to 150,000. Help has been given both by gifts of clothing and by the introduction of agricultural machinery. The health conditions, it is stated, have materially improved, although malaria has been rampant. Under the direction of the Committee's medical officer, Dr. M. D. Mackenzie, an epidemic hospital at Buzuluk has been reopened, and ten other hospitals have received equipment and food to enable them to begin their work again. The feared epidemic of cholera did not occur, but cholera vaccine sufficient for 100,000 persons was distributed to the local doctors. A sanitary guard has been established at Buzuluk station to watch for cases of typhus, and a bacteriological laboratory has been set up. Russian doctors have taken a responsible share in the work, and arrangements have been completed for them to carry it on after the mission leaves, as is intended, during this summer. The confidence in Austria, restored by the determination with which the League of Nations scheme for financial reconstruction is being carried out, will, it is hoped, enable the commission in that country to be withdrawn this summer. The mission has continued its care of tuberculous, rachitic, and under-nourished children by subsidizing their maintenance in homes. The difficulty of obtaining fresh milk for children and sick people in Vienna has been met by establishing a system by which cows are imported and handed over to farmers in the neighbourhood of Vienna who undertake to deliver stated quantities of milk daily for a period of eight months, until the cow has paid for herself in milk and so belongs to the farmer. Over 1,000 cows have been disposed of in this way. The quantity of milk distributed daily in April, 1922, was over 4,000 litres. Special milk in sealed bottles is supplied to 2,000 infants, and since last summer children's institutions have been supplied with fresh milk at one-third of the market price. This accounted for 1,500 litres, and about 4,000 more were delivered daily to individuals, including 1,000 to patients from tuberculosis dispensaries. During February, 1923, about 7,000 litres were distributed daily to children and tuberculous patients. Altogether some 14,000 persons in Vienna and the provinces were daily receiving milk from the mission's cows. All this, of course, meant a big organization; there were 47 distributing centres in Vienna. The Committee, as we understand, intends to close its mission in Poland this summer, after three years'

work. Welfare centres have been established in several towns, and are now being administered by Poles, as is also the school of gardening at Dykainow.

## THE INDUSTRIAL COLONY IN THE TREATMENT OF TUBERCULOSIS.

The spring meeting of the Border Counties Branch of the British Medical Association was held on April 20th, at Englethwaite Industrial Colony, by invitation of the Cumberland County Council. A tour of inspection of the Colony was made during the afternoon, special attention being paid to the poultry farm, the joinery shop, and the other branches of industry in which the patients are engaged. Afterwards an address was given in the recreation hall by Dr. P. C. Varrier-Jones, of Papworth Industrial Colony, Cambridge. Dr. W. Scott, Ruthwell, Dumfries, president of the Branch, being in the chair. Dr. Varrier-Jones said that Papworth was the pioneer institution of the kind in England. Beginning in temporary work as a tuberculosis officer he sat at a desk, and to one patient he would recommend "a light job," to others "a generous diet and plenty of cream." Quite suddenly, one day, he was told that what a patient desired from his doctor was hope, and he thought over again the advice he had given to his patients. If a light open-air job existed, there must be light wages at the end of the week, and he found that he had been advising men to do something which, if coupled with good wages, did not exist. He began to wonder whether it would be possible to give a man an opportunity of living under conditions in which disease, partially arrested in a sanatorium, could continue to be arrested during the remainder of his days. In Cambridgeshire the assistance of the friendly societies was invoked, and the institution at Papworth begun in quite a small way. It had to be realized that the ordinary working man was not nowadays a craftsman—the craftsman's days were over, for an "engineer" now minded a machine, and a "bootmaker" did only six inches of separate sewing to a boot which went through seventy to be subsidized, but this subsidy was an insurance by the community against infection. Public opinion was with the Papworth scheme, and tuberculosis was there treated right down to its very base in the home. The wives and families of the men were there, but so far there had not been one case of infection.

## THE THIRD JUBILEE OF THE MEDICAL SOCIETY OF LONDON.

As already announced, the 150th Anniversary Dinner of the Medical Society of London will be held at the Hyde Park Hotel on Tuesday, May 15th. The principal guest will be the Prince of Wales. The toast of "Medicine and the Medical Society of London" will be proposed by Mr. Lloyd George and responded to by the President, Lord Dawson of Penn. The toast of "The Sister Professions and the Guests" will be proposed by Sir John Bland-Sutton, F.R.C.S., and responded to by the Lord Chief Justice (Lord Hewart) and by the Minister of Health (Mr. Neville Chamberlain). Fellows and their guests will pass through the grill room entrance and will be received by the President at 7.30. It is requested that at 7.45 Fellows and their guests will take their places at the dinner tables in order that the audience may be seated before the arrival of the Prince of Wales. The history of the Medical Society has often been told. It was founded by Lettsom with Dr. John Millar as president and Lettsom as treasurer. The first meeting was held in May, 1773. Two years later Lettsom succeeded to the presidency, and there can be no doubt that it was mainly through his influence and generosity that the Society survived, the only one of many founded about that time. It is

interesting that among the guests at the dinner next week will be a member of the Lettsom family. Dr. John Fothergill, though not a member of the Society, was a friend and patron of Lettsom, who in 1784, soon after Fothergill's death, founded a Fothergillian gold medal in his honour; the family will be represented at the dinner by Dr. Fothergill. Among other guests are the presidents of the Royal Colleges of Surgeons of England and of Ireland, of the British Medical Association, of the Royal Society of Medicine, and of the Royal Academy; the Minister of Health, Professor Sir Clifford Allbutt, and Professor Sir Archibald Garrod, the Bishop of Birmingham, Sir John Goodwin, Sir William Leishman, together with Sir Alfred Yarrow and many other representatives of science.

#### THE HOSPITAL POLICY OF THE ASSOCIATION.

We publish this week at page 835 a letter from the Chairman of the Hospitals Committee of the Association, and at page 817 a short history of the events which have brought the discussion of hospital policy to its present position. The correspondence has served a useful purpose by enabling the protagonists to put their divergent views before the profession in their own words, but it cannot profitably be continued. The next, if not the final, word is with the Representative Meeting at Portsmouth in July, which will have before it the report on the subject embodied in the Council's annual report published in the SUPPLEMENT of April 28th.

THE Association of Surgeons of Great Britain and Ireland met in London on the last three days of last week; Mr. Raymond Johnson presided. The Association does not permit publication of a report of its proceedings, wisely no doubt, in order to encourage freedom in debate and frankness in criticism. On Saturday morning demonstrations were given at the Royal College of Surgeons by Sir Arthur Keith, F.R.S., and Professor S. G. Shattock, F.R.S.

THE Croonian lectures before the Royal College of Physicians of London will be given by Professor J. B. Leathes, F.R.S., on the subject of the part played by fats in vital phenomena. There will be four lectures, which will be given at 5 p.m. on Tuesdays and Thursdays, beginning on June 7th.

THE annual oration before the Medical Society of London will be given on Monday next, May 14th, at 9 p.m., by Dr. J. Walter Carr, who has taken for his subject "Life and Problems in a Medical Utopia." The guests will be received by the President, Lord Dawson of Penn., at 8.30, and the lecture will be followed by a conversazione.

KING GEORGE V, when Prince of Wales, was an honorary Fellow of the Royal Society of Medicine. We announced some time ago that the Prince of Wales, having consented to accept the honorary fellowship, had been duly nominated and unanimously elected. On May 4th, at St. James's Palace, he received the diploma at the hands of the president, Sir William Hale-White, who was accompanied by the honorary secretaries, Dr. A. M. H. Gray and Mr. Girling Ball, and the secretary, Sir J. Y. W. MacAlister.

Among those upon whom the University of Cambridge will shortly confer honorary degrees are Dr. W. H. Welch, director of the School of Hygiene, Johns Hopkins University, Baltimore, and Dr. J. T. MacCurdy, formerly of the same university, but now lecturer in psychopathology in the University of Cambridge.

## EXCHANGE PROFESSORS.

### VISIT OF SIR HAROLD STILES TO BOSTON.

AN interesting precedent has been established by the recent visit of the Regius Professor of Clinical Surgery at Edinburgh University to Harvard to act temporarily in the place of Professor Harvey Cushing. Sir Harold Stiles, who has just resumed his regular duties in Edinburgh, carried out for the last fortnight of the Harvard session the teaching in clinical surgery at Boston and the duties of surgeon to the Peter Bent Brigham Hospital in that city. The system of "exchange professors" has been in vogue at the Harvard School for eight years, and while Sir Harold Stiles was in temporary occupancy of the Chair of Surgery, Professor Connor, from Cornell University, New York, acted for a fortnight as "exchange professor" in Medicine. The practice is one which presents great opportunities of new experience both to professor and students, and it is hoped that Edinburgh University may show reciprocity by welcoming an American professor for a short period to one of its chairs.

The Harvard Medical School presents some interesting contrasts to the Edinburgh system. In the first place the number of students is limited to 120 entrants in each year. A further process of selection is exercised by means of a preliminary science examination; the early science subjects are studied apart from medicine, and after the examination in these is passed the medical course proper lasts four years. In addition to this at Harvard the entrants for medicine are selected from those holding degrees of the best recognized universities in the States.

As regards facilities for clinical study, Boston is particularly favoured by the large number of well equipped hospitals in the city. This is largely due to the fact that all classes of the community have recourse to hospital for treatment and that the hospitals are well supported by the charges levied on the more affluent patients using them. The Peter Bent Brigham Hospital contains 226 beds, and here the surgeon-in-chief and physician-in-chief respectively are Professor Harvey Cushing and Professor Henry A. Christian of the Harvard Medical School. The Massachusetts General Hospital has 358 beds and the Boston City Hospital 1,209 beds. Between these three general hospitals the students are apportioned for clinical study and instruction and there are some ten affiliated special hospitals for infectious diseases, mental diseases, diseases of the eye, diseases of the ear and throat, diseases of children, etc., where students may take the elective courses to be mentioned later. As examples of the extent of equipment it may be mentioned that the teaching staff of professors, assistant professors, instructors, etc., on the active list of the Harvard Medical School numbers 102, and that in the Boston City Hospital, besides the ordinary pathological and x-ray laboratories, there are special laboratories for the study of haematology, of asthma, of pneumonia, of renal function including nephritis and diabetes, of physical therapeutics, and of immunology.

The method of whole-time appointments, towards which there was at one time a movement in America, is not carried out at the Harvard Medical School. The surgical staff of the Peter Bent Brigham Hospital consists of the surgeon-in-chief, Dr. Harvey Cushing (who gives special attention to surgery of the nervous system); the surgeons, Dr. David Cheever and Dr. John Homans; the urological surgeon, Dr. William C. Quinby; and the surgeon for out-patients, Dr. Elliott C. Cutler; in addition to their ordinary hospital duties they have their private cases in the hospital also. They are assisted by associates and by five resident surgeons who live in the hospital; their ultimate intention is to specialize in surgery, and they hold the appointments indefinitely but usually for a period of several years. Lastly there is a group of six recently graduated house officers who take the case histories, help at operations, and in the case of the two juniors, colloquially known as "pups," attend to routine examinations such as that of the blood, urine, etc.

A few words may be said next as to the means of mutual instruction practised by the staff: it forms a feature much more distinctive of American than of home hospitals. A strong effort is made to unify the staff by the utmost

possible amount of co-operation and co-ordination. Thus all its members, visiting and resident, meet daily at lunch in the common room. On one day in each fortnight the whole surgical staff go to the medical side of the hospital, where there is held a two-hour clinic and open discussion upon the borderland cases which have previously been carefully worked up; and on a day in the intervening weeks the process is reversed and the medical staff receives a clinic in the surgical department. A similar arrangement is made at intervals between the staff of the Peter Bent Brigham Hospital and that of the Children's Hospital, which is also a department of the Medical School. Every Monday the radiographer spends an hour in demonstrating to the assembled staff the radiograms produced during the preceding week; and a similar critical demonstration is held once a week in the pathological department. All these meetings in a well equipped hospital have the inestimable advantage that the hospital affords post-graduate instruction to the staff as well as constituting a teaching centre for students.

Finally there are some striking points in the curriculum for students at Harvard differing from the course of study usual on this side. There is a general disposition to recognize that the duty of a medical school is in the first place to turn out men who will be efficient general practitioners, while at the same time it holds out the possibility of wider qualifications to those who desire and are able to assimilate them. It is admitted that for the average student the medical course has been made too full, so that too little time has been available for self-education. Accordingly the 1,300 hours of compulsory study previously demanded in each academic year at Harvard have been reduced to 900 by a process of cutting down all round. For example, in physiology 230 hours are now requisite instead of 320 as before, and of these only 30 hours are spent in attending didactic lectures. Demonstrations and "talks" to sections of the class have to a large extent taken the place of didactic lectures. At the same time overlapping of different departments is prevented by prescribing a syllabus for each, so that histology, for example, is included in the subject of anatomy, and the physiology of digestion is relegated to the department of biological chemistry. The saving of hours which has been effected enables some 15 per cent. of the best men in each year to take out special "elective" classes, and these men are encouraged at a later stage to specialize in the departments to which they have devoted special study.

A feature of the Harvard clinical teaching which deserves consideration elsewhere is the "intensive" system. This consists in taking the students in small sections of six at a time; they spend the whole working day for a limited period of a few weeks at clinical medicine or clinical surgery as the case may be, and then make way for another section of the class.

A word may be said in conclusion as to the way in which the Peter Bent Brigham Hospital is supported, since this is typical of the American general hospital. Of the patients treated in hospital during 1922, 58 per cent. were paying patients, by which is meant that they paid the regular rates, not necessarily the full cost; 20 per cent. paid something, but not full rates, and 22 per cent. made no payment. Private patients are divided into two classes—those who can afford to pay full charges, and those of small means for whom the schedule of charges is lower. A statement by the Superintendent may be quoted: "If it were not our custom to ask all patients to assist the hospital by paying what they can, we should be unable to do nearly as much for them as we now do. How important this is may be shown by the following figures, that of the total sum expended in 1922, only 35 per cent. was received from the income of endowed funds. The other 65 per cent. was collected from the patients, and no hardship whatever placed upon them."

The Mackenzie-Davidson memorial lecture will be delivered by A. W. George, of Boston, Mass., at a joint annual meeting of the Röntgen Society and the Electro-therapeutic Section of the Royal Society of Medicine, to be held at the Royal Society of Medicine, 1, Wimpole Street, W.1, on Thursday next, May 24th, at 5.30 p.m. The subject selected for the discourse is the pathological gall bladder. A dinner will be held the same evening at the Langham Hotel at 8 o'clock.

## Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

### Mental Treatment Bill.

SECOND READING DEBATE IN THE LORDS.

#### Statement for the Government.

THE Earl of Onslow moved, on May 3rd, in the House of Lords, the second reading of the Mental Treatment Bill which was introduced as a result of a conference arranged last year by the Board of Control of chairmen of visiting committees, medical superintendents of mental hospitals, and a number of specialists; the conference decided to ask the Government to introduce legislation permitting treatment without certification in institutions approved by the Board of Control. At present the law as to lunacy might be divided into three definite parts. The first dealt with detention to prevent lunatics injuring themselves or other people; the second was devised for humane and proper treatment of such patients; and the third to secure their property against fraud or misappropriation. The Lunacy Law did not deal exhaustively with cure, the reason perhaps being that scientific knowledge of treatment was not sufficiently advanced when the principal Act was passed. The importance of this aspect of the matter was made evident in the fact there were now 120,000 certified lunatics in 172 institutions, costing £6,000,000 a year. To these were added 22,000 fresh cases every year, of whom 32 per cent. were discharged as recovered. Besides certified lunatics there were 150,000 feeble-minded persons and, in addition again, a percentage of the population (some people said as high as 10 per cent.) was dull and backward mentally. Lastly there were the cases of neurasthenia and psychoneurosis. All this constituted a serious drain on the nation's capacity, and much of it was preventable by careful watching and early treatment. As the law stood it was, at least, very difficult to provide for treatment of incipient mental disease without certification, and there was a strong feeling against certification if avoidable. This led to delay in proper treatment until too late.

The chief purpose of the bill was to provide that a patient suffering from incipient mental disorder might be received for treatment without certification. Such course had been taken for many years in Scotland, and in this country, under the Act of 1890, voluntary boarders had been allowed in private licensed houses. The desire, of course, was to surround the proposal in the present bill with every possible safeguard against misuse. First of all the institution in which the patient was to be received must be approved by the Board of Control and under frequent inspection by that body. Secondly, there must be a recommendation from two doctors. Thirdly, no patient could be admitted unless it was at his own request—a voluntary request. There were many cases of incipient mental disease in which the persons were incapable of volition; before such a person could be admitted, the recommendation of the two doctors would have to be countersigned by a justice of the peace, or a minister of religion personally acquainted with the patient but not related to him, and the person signing this document must have seen the patient and have satisfied himself that he was incapable of volition. A similar procedure was required in the case of minors, and, of course, in addition the consent of the parent or guardian must be obtained. One at least of the doctors must be a medical man approved by the Board of Control. The patient would go into the institution at first for a maximum period of six months, which might be extended for another maximum of six months. If he were not recovered within a year, the ordinary provisions of the law would apply, but at any time during the year he might leave the institution by giving forty-eight hours' notice, or he might be discharged by the superintendent or by order of the Board of Control.

Lord Onslow next touched upon the places which would be provided for the treatment of such patients. Under Clause 1 (3) county and borough councils, acting through their visiting committees, would be able to receive patients into their own institutions. Under Clause 4, visiting committees should be able to arrange for general hospitals to receive patients of this kind, these bodies working in conjunction with the committees. If this could be done, great advantage to patients might ensue by getting them away from contact with certified cases, and it would enable all the resources of medicine, other than those provided especially for mental disease, also to be at the disposal of the patient. The patient could, moreover, be received in registered hospitals which were mostly charitable foundations or licensed houses which were otherwise known as private asylums. Another provision of the bill enabled visiting committees to provide out-patient treatment for persons suffering from mental disorder. They would be at liberty to do this either in institutions under their own control, or by arranging for it to be done in general hospitals in the same way as they

would be empowered to arrange for in-patients. An outdoor clinic for nervous and mental cases was already established at the Radcliffe Hospital, Oxford, with the greatest possible success. No difference was made between nervous and mental patients. They all went to the same hall for treatment. It had been found that patients and their friends were much more ready to come to a clinic of this kind than to a separate mental hospital. The bill would also authorize visiting committees to make provision for the after-care of patients. It had been found that many discharged as cured broke down again unless carefully and kindly looked after in subsequent months.

Despite the advance made in knowledge of mental disease during the last quarter of a century, many of the causes of mental illness were largely unknown. Therefore in Clause 2, Subsection (5), provision was made for more systematic research, and for the expenditure of public money on research undertaken with the approval of the Board of Control. The bill involved the extension of the functions of the visiting committees, and it was therefore proposed that a portion, not exceeding one-third, might be persons who were not members of the council. This was the principle adopted in regard to education committees and some others, and was designed to enable the committees to co-opt experts, and to get the services of people willing to give a large part of their time to such work. At least two members of these visiting committees would be women, and power was given to the committees to carry on their duties jointly with other authorities. The expenses of visiting committees were to be defrayed by the local authorities. The cost of maintaining cases treated for incipient disease would not be a charge on the Poor Law. The cost would fall on the general fund and not on the boards of guardians.

The Mental Deficiency Act of 1913 greatly increased the amount of visiting and raised the number of commissioners to eleven. At present there were seven commissioners, one a woman who, being neither a lawyer nor a doctor could not pay statutory visits. In the view of the Ministry of Health, many of the visits and work now done by the commissioners could be undertaken by the inspectors. It was proposed to limit the number of commissioners to eleven, and to allow the rest of the work to be performed by inspectors.

#### Discussion.

Lord Buckmaster, while welcoming the bill, was not certain that its provisions would be fully effective. In the early stages of mental disorder there was peculiar, almost insane, resistance to any form of treatment or control. Consequently, he should be surprised if, when people had been recommended and had been placed under control by virtue of this bill, the forty-eight hours' notice were not given very speedily, and the whole benefit derivable broken down. There should, he thought, be greater power for the treatment of these cases—with proper safeguards. If persons were suffering from infectious diseases there was power to isolate them in the interests of the community. He thought that somewhat similar power might be given here; in his opinion the time had come when the whole question of the propagation of the mentally weak and unsound should be the subject of full investigation, and he wished that the Government would have the courage to appoint a Royal Commission on the subject.

The Bishop of Worcester warmly commended the bill. He thought that as the term "mental hospitals" replaced "asylums" the fear of treatment in such places would be relieved. Dr. Pearce paid a tribute to the medical staffs of these homes and he went on to deplore the effort made in certain sections of the press to cover them with abuse.

Earl Russell, in supporting the bill, commended the provision for expenditure of public funds upon after-care. In regard to the need for the main proposal in the bill, a distinguished alienist had said to him "our treatment in lunacy is just about as sensible as if we did not begin to treat a patient for scarlet fever until he was in the peeling stage." He shared the view of Lord Buckmaster that the benefit of the bill was liable to loss from the forty-eight hours' notice. He suggested that discharge should be subject to an order of the Board of Control. They were a public body and could have no pecuniary or personal interest in the detention of anyone.

The Earl of Onslow, replying, expressed pleasure at the reception given to the bill. He was unable to say anything at present on the appeal made to him against the forty-eight hours' qualification, for to remove it would be taking a very considerable step. He promised, however, that all amendments should have full attention.

The bill was then read a second time.

#### National Health Insurance Finance.

Sir Worthington-Evans inquired, on May 2nd, what were the amounts of the Reserve Value Contingency Fund and the Control Fund, respectively, at the end of 1921, and against what liabilities each of these funds had been accumulated; and whether any part

of them was available for medical benefit or to supplement payments made to the panel doctors.

Mr. Chamberlain said that there was no fund called the reserve value contingency fund, and it was assumed that reference was made either to the Reserve Values (Apportionment) Account, or the Reserve Suspense Account. The Reserve Values (Apportionment) Account was applied in accordance with the provisions of the Insurance Acts in discharging the liabilities of the Minister to approved societies in respect of reserve values created under the Acts, and could not be applied to any other purpose. The amounts carried to the account were periodically apportioned among approved societies, but at the end of 1921 there was a balance of some two million sterling in the account not apportioned pending determination of the precise amount of reserve values to be created under Section 16 of the Act of 1920. The net amount standing to the credit of the Reserve Suspense Fund at the end of 1921 was approximately £389,000, but this was merely a provisional balance pending completion of adjustments for the purpose of giving financial effect to the changes of membership that had occurred since the date of the last valuation. When these adjustments had been carried out, it was anticipated that the balance would be negligible. The Reserve Suspense Fund was constituted of the amounts transferred from approved societies and from the deposit contributors' fund on the cessation of insurance by members of societies and deposit contributors as the case might be, and had to be applied, as far as it was sufficient, to provide the reserve values required in respect of persons coming into insurance, and of deposit contributors becoming members of societies. The amount of the central fund at the end of 1921 was approximately £2,000,000. The central fund was established under the National Health Insurance Act, 1918, for the purpose of meeting the residual part of any deficiencies at valuation remaining over (after the available contingencies funds of the societies concerned had been exhausted) in cases where the joint committee were satisfied that the deficiency was due to an abnormal rate of sickness attributable to certain specified causes, or to any other special cause beyond the control of the society or branch. By the Insurance Act, 1922, the fund was liable to make good to the benefit funds of approved societies seven-ninths of one-third of the sums paid out of those benefit funds towards the additional payments in respect of the cost of medical benefit and the expenses of administration of medical benefit provided for by that Act up to the end of 1923. Having regard to the existing liabilities of the fund, it could not be regarded as in any respect available for any other purpose.

**Combined Public Health Appointments.**—Mr. Gavan Duffy on May 7th asked whether the Minister of Health, before sanctioning the appointment of a medical officer of health for the urban district area of Frizington, Cumberland, would consider the recommendation of the medical officer for the county of Cumberland that several small urban areas should be combined under one full-time medical officer. Lord Eustace Percy, for Mr. Neville Chamberlain, said that no formal request had been received, but the Minister had tried to arrange for such appointment by agreement. Having been unsuccessful, he did not think it practicable to object to the district council's proposal to appoint a part-time officer, but such officer had been required to give a written undertaking to resign the appointment in the event of a whole-time officer being appointed. Mr. Gavan Duffy asked if the Minister was aware that the doctor nominated for the appointment did not live at Frizington, and Lord Eustace Percy said that if information to this effect were given inquiry would be made.

#### Answers in Brief.

The proposal to amalgamate the naval and military hospitals at Hong Kong has been rejected by the Admiralty, and also by the committee appointed by the late Government to deal with the possibility of amalgamating the Services common to the Navy, Army, and Air Force.

Uncertified deaths in 1922 numbered 5,487.

The total amount of the grants paid to Scottish local authorities in the year 1922-23 in aid of their expenditure in the treatment of tuberculosis was £289,998 15s. 6d. The provision made in the 1923-24 estimate of the Scottish Board of Health shows no reduction on that figure; the amount provided for payment of grants in 1923-24 is £290,000.

The Minister of Health had undertaken carefully to consider the question of including in the next bill to amend Health Insurance Acts a clause to enable insured persons, no longer employed, between the ages of 65 and 70, to remain entitled to medical benefits on payment of a weekly contribution sufficient to cover the cost of that benefit.

In reply to a question on May 2nd, the Minister of Health said that he was unable to state that the sporadic outbreak of small-pox in the North Midlands had been arrested. Probably the infection was introduced from abroad, but no definite evidence was available. Memoranda upon the steps requisite to be taken on the occurrence of small-pox had recently been issued by the Ministry to all sanitary authorities and boards of guardians throughout the country. He did not think it practicable to take any other steps to guard against further outbreaks.

Mr. Ponsonby has elicited the information that no representations arising out of the discussion in the House of Representatives last January have been made to the British Government by the United States Government as to the necessity of limiting the production of opium to the amount actually required for medicinal and scientific purposes.

The Minister of Health has stated that he hopes shortly to reach a final decision as to the establishment of additional tuberculosis settlements such as those at Papworth Hall, Cambridgeshire, Barrowmore, Cheshire, and Preston Hall, Kent.

## ROYAL MEDICAL BENEVOLENT FUND.

THE annual meeting of the Royal Medical Benevolent Fund was held at the Royal College of Physicians on May 7th, under the presidency of Sir THOMAS BARLOW.

The CHAIRMAN said that the objects of the Fund were twofold: firstly, to provide annuities for necessitous practitioners who had passed the age of sixty, and, secondly, to give emergency grants to medical men and to their widows and orphans who were in urgent need. In addition there was the very important Guild, founded by Lady Tweedy and managed by ladies, which helped materially in the investigation of claims and in the raising of funds. During the year under review 168 annuitants had each been allotted a sum of £20—not a large amount, but it was hoped later to be able to increase it to £26. During the war and subsequently a special fund had been raised to help patriotic doctors who, in army service, had sacrificed a considerable part or even the whole of their practices. Most of the £30,000 which had been raised had now been expended, but the Fund was still under obligations with regard to charges for the education of children of the medical men concerned. In 1922 the income of the general fund from subscriptions was £3,503, and the expenditure in grants £4,966. The income from investments was £4,166, and the annuity expenditure £4,458. The total deficit was thus £1,754. The demands had been very heavy, and the number of new applicants nearly double that of previous years. The total number relieved was 483. Although the Fund was mostly maintained by medical men, he looked for some help from the intelligent lay public who realized the obligation of the community to the medical profession.

The ARCHBISHOP OF CANTERBURY said that he was genuinely grateful for the privilege of speaking for those outside the profession. Members of the general public had comparatively rare opportunities of expressing their sense of the value of the services rendered to the whole community by doctors. Politicians, soldiers, and sailors gained applause on various occasions of public interest and importance, but he did not know of a single instance in which medical men had received a cheer. Those who had intimate acquaintance with members of the profession were aware of the hardships the war had brought to many of them. Men returned after years of service, having contributed splendidly to the common good, to practices diminished or disappearing. He could bear witness from his personal experience to the way in which service of the highest possible skill was given in medicine and surgery for the alleviation of suffering quite freely as a matter of public spirit and kindheartedness. Such services were quietly rendered and quietly received, and from the very nature of the case the public did not hear of them. He felt that many of the lay public would desire to repay in some way the debt they owed to the profession. The Fund showed the need to be obvious and provided the channel.

LORD SUMNER (Lord of Appeal), in seconding the motion, said that there were two things the public hardly realized with regard to medical men—namely, that the profession was not a rich one, and that it was a profession in which very few opportunities were given to the average man of successfully using to the best advantage such money as he had. The life of a doctor in a manufacturing district, for example, always appeared to him to be one in which the maximum of dreariness and drudgery was charged upon a man whose labours demanded—and, once he had thought, entitled him to—the maximum of relaxation. It was a life in which very often there were only two earthly sources of consolation, the one the consciousness of good work done, and the other the family life. If, however, that family life was clouded by the knowledge that should any illness befall the breadwinner it would go very hard with his dependants, it was a very sad thing, which more generous public support for the Fund would help to remove.

SIR HUMPHRY ROLLESTON said that whereas Churchmen remained uncontaminated by the sins they made war on, and legal luminaries were too wise to engage in litigation on their own account, members of the medical profession were liable to in- from their patients, and were, therefore, relatively little but hope and energy to support them, often had to leave off without having made

adequate provision for retirement was only too clearly shown by the cases that came for relief to the Fund. As practitioners they were bound to make an appearance of greater prosperity than the bank book would justify, and the contrast between their apparent prosperity in life and the condition of widow and children afterwards was painful. Only one-tenth of the profession in Great Britain subscribed to the Fund, and he was sorry to say that London was far from taking the lead, only 7 per cent. of the members of the profession subscribing.

The Annual Report and Financial Statement (summarized in the Chairman's remarks) were adopted, and on the motion of Dr. HERBERT SPENCER, seconded by Sir DYCE DUCKWORTH, Sir Thomas Barlow was re-elected President, Sir Charters Symonds Honorary Treasurer, Dr. Newton Pitt Honorary Secretary, and Dr. Arnold Chaplin Chairman of the Case Committee. The Vice-Presidents, Committee, and Auditors were also re-elected, and on the motion of Dr. O. LANKESTER a vote of thanks was accorded to the Press, and especially to the Editors of the *Lancet* and the *British Medical Journal*, for publicity given to the Fund during the year.

## THE SPAHLINGER TREATMENT.

THE search for an infallible remedy for the treatment of tuberculosis is as alluring to-day as was ever the quest for the philosopher's stone. It has been pursued intensively for well over a hundred years and yet many would still subscribe to Laënnec's pessimistic statement that the "cure of tuberculosis is not beyond the powers of Nature, but it must be admitted at the same time that Art possesses no means of attaining this desirable end."

Every week some new preparation or nostrum is brought to the notice of the medical profession, but on trial proves to be the fairy gold of medication turning to ashes in the morning.

Men of science have been equally led astray and, like Sir Walter Raleigh, have brought vain news of an Eldorado for the victims of tuberculosis. Many of us can recall the high hopes that were raised by the announcement of Koch's tuberculin and of Marmorek's serum, hopes that at first appeared to be fully justified by the successful treatment of a few cases.

At the present time the medical profession has to consider the problem of M. Henri Spahlinger's method of treatment, and in view of the experiences of the past it is not surprising that hitherto its leaders have suspended judgement on the matter. It is equally true that many of those who have visited M. Spahlinger's laboratory have recognized in him an enthusiastic and serious worker, whose claims demanded and have obtained consideration at the hands of experts in tuberculosis either acting independently or as the advisers of the health authorities in various countries. We last referred to the matter three months ago (February 10th, 1923, p. 252), when we stated that inquiries into the nature and results of M. Spahlinger's methods had been made both by the Red Cross Society and by the Ministry of Health, and added that we had reason to believe that the methods were looked upon as interesting and the results, though hitherto on a very small scale, as encouraging.

With regard to the action of the Ministry of Health in the matter we gather that from the beginning such statements as M. Spahlinger has published in England and France have been carefully noted by the Ministry; in 1920 special medical inquiry was made and all the testimony then available was considered; this evidence included clinical reports from physicians practising at Geneva, Montana, Hamburg, and London.

In 1922, through the courtesy of M. Spahlinger, a medical officer of the Ministry was enabled to visit the Bacterio-Therapeutic Institute, Carouge, Geneva, and to examine certain cases of tuberculosis, treated by the method. The conclusions arrived at were that although it is not yet possible to express an opinion upon the scientific value of M. Spahlinger's work from the bacteriological standpoint inasmuch as the details and the technique adopted in the preparation of serum and vaccine remain undisclosed, the clinical results already obtained in Switzerland and in England warrant further investigation. We are informed that the cases examined by the medical officer included examples of lupus,

tuberculous glands, and bone and joint tuberculosis, in addition to pulmonary tuberculosis. The histories were well authenticated; in the pulmonary cases tubercle bacilli had been present in the sputum and some of these cases had been in an advanced stage and their condition regarded as hopeless prior to the initiation of M. Spahlinger's treatment. Radiological evidence also was forthcoming in a number of the cases; it showed the conditions before and after treatment by M. Spahlinger's preparation. Making every allowance for the fact that a certain proportion of patients suffering from tuberculosis got well under any conditions, the complete or partial arrest of active and extensive disease produced in these cases in a short period of time after the administration of M. Spahlinger's remedies and remaining permanent through several years' observation appears to be a striking contribution to the evidence for the efficacy of the treatment.

The Ministry, through unofficial channels, intimated to M. Spahlinger that with his consent it would be prepared to appoint a committee of recognized medical experts who would watch the results of his method of treatment in a number of cases to be selected by a physician nominated by M. Spahlinger and who after due trial would report on the value of the treatment. It was understood that M. Spahlinger would not be required to divulge the technique by which the serum and vaccine are prepared.

This offer lacked nothing on the side of generosity, but, unfortunately, M. Spahlinger did not accept it. M. Spahlinger makes a "complete" serum and a "complete" vaccine, but it would seem that in 1914 he had practically exhausted his supply of both. Since that date he has continued the preparation of partial serum in small quantity and it has been used for the treatment of a few cases. The preparation of the complete serum is stated to be a long and complicated process, and it would appear that at present M. Spahlinger can assign no definite date for the production of the serum in large quantities for general use or even for the purposes of an experimental investigation such as that proposed by the Ministry of Health. The offer made is, we understand, still open. No later than March 21st last the Minister of Health, in reply to Dr. Watts in the House of Commons, stated that he was most anxious to encourage further trial of the remedies in this country as soon as supplies were available.

We understand also that M. Spahlinger has exhausted his financial resources in the prosecution of his researches and that pecuniary embarrassments still further delay the production of his long awaited preparations. The British Red Cross Society, mindful of the interests of ex-service men, has interested itself in the matter, and we understand that some time ago it made M. Spahlinger an offer of financial assistance under certain conditions.

We have heard—a preliminary notice to this effect was indeed made some months ago—that an influential movement is on foot to issue in this country a public appeal for funds which shall relieve M. Spahlinger of his financial disabilities. We have very little doubt that should it be found possible to make a satisfactory arrangement with M. Spahlinger, sufficient money would become available in this country alone, and there is reason to believe that some of the Dominions also would be willing to make contributions.

Should the financial disabilities from which M. Spahlinger is now suffering be removed, we would urge him, not only in his own interests, but in the general interests of humanity, to submit the first supplies of the serum and vaccine when obtained to a scientific tribunal whose decision, if favourable, would rank him indisputably among the great benefactors of mankind and which would lay open a great avenue of hope to those enrolled in the company of the Captain of the Men of Death, as Bunyan phrases it.

We would emphasize our belief that the world is ripe for the discovery of a successful method for the treatment of tuberculosis. Following on the labours of Koch and others, workers of repute are engaged in attempting to solve the same problem as that to which M. Spahlinger has devoted his gifts and fortune. Already results have been achieved in the serological investigation of tuberculosis which are full of promise. M. Spahlinger must not delay to bring forward scientific proof for the considerable claims he has advanced. It may be remembered that Adams was forestalled in his mathematical discovery of the planet Neptune by Le Verrier.

## Victoria.

### THE FIRST AUSTRALASIAN CONGRESS OF THE BRITISH MEDICAL ASSOCIATION.

THE medical profession in Australia has learned with pleasure that it is the intention of the President of the parent Association to be present at the first Australasian Congress of the British Medical Association, which is to be held in Melbourne from November 11th to 17th. Sir William Macewen is assured of a hearty welcome, and it is hoped to induce him to open the new Anatomy Department in conjunction with the University Council.

An exhibition of trade products, including medical and surgical instruments, books, drugs, foods, and other articles of direct interest to the medical profession will be held in the new Anatomy Department of the University of Melbourne during the Congress. Exhibitions from Great Britain will be particularly welcome; a special feature is being made of this section of Congress activities. Intending exhibitors from Great Britain should put themselves in communication with Dr. B. L. Stanton, Children's Hospital, Pelham Street, Carlton, Melbourne, as soon as possible, and should allow a period of about twelve weeks for the dispatch and receipt of letters. Cable messages to Dr. Stanton will, of course, secure prompt attention.

### THE WAR MEMORIAL OF THE VICTORIAN BRANCH OF THE BRITISH MEDICAL ASSOCIATION.

A very beautiful memorial in bronze has been executed by the sculptor, Mr. Webb Gilbert, to the order of the Victorian Branch of the British Medical Association, to commemorate those members who laid down their lives for King and country in the war. Pending the erection of a new building for the local branch of the Association, this memorial is to be placed in the new Anatomy Department. The unveiling of this beautiful masterpiece of art will be one of the special features of the Congress to be held in November; the site selected is naturally the best in the building.

### THE UNIVERSITY OF MELBOURNE.

Dr. W. A. Osborne, Professor of Physiology, has returned to Melbourne after a study leave of absence in America and Great Britain.

The number of first year medical students entering the University continues to fall; it is now little more than a third of the entries in 1919, which was the maximum year. Coincident with this decline in the numbers there has been a great advance in the efficiency of University teaching. Changes in the curriculum—namely, an examination in anatomy and physiology at the end of the second year—a slight increase in the fees, and a lengthening of the whole curriculum, have probably tended to reduce the entries but have enhanced the University's efficiency. The imposition of an examination in anatomy and physiology in both second and third years has been welcomed by both students and staff; the former recognize the newly introduced second year examination as an inducement to work and as making the work of the third year somewhat easier, and the latter are assured of an enhanced degree of efficiency all round.

## Scotland.

### HONORARY DEGREE OF DOCTOR.

At the statutory half-yearly meeting of the General Council of the University of Edinburgh, Principal Sir J. Alfred Ewing, K.B.E., presiding, the chief item of business was a discussion on the report of a subcommittee appointed to inquire into the regulations under which the degree of Doctor was granted. The council approved of the report on the following heads: (1) That every graduate should have the right to proceed to the degree of Doctor in his own faculty under appropriate regulations, including the degrees of D.D. and LL.D. (2) That a graduate with honours or distinction should be permitted to proceed to the degree of Doctor within a shorter time than the holder of an ordinary degree. (3) That the minimum time which

must elapse after graduation and before examination for the degree of Doctor should be the same in all faculties; and that a reasonable minimum for graduates with honours was two years and for ordinary graduates three years. (4) That an approximately uniform standard should be aimed at for the degree of Doctor in all faculties. Other recommendations of the committee, upon which no opinion was expressed by the Council, were that degrees of Doctor should be given *honoris causa* to persons eminent in the subject of the particular degree, as well as by examination; and that in the case of persons who merited honour from the University, but who could not claim distinction or ability to pass examination in any faculty, no degree should be given but these persons should be admitted "Honorary Fellows of the University." It was decided to ask the councils of the other Scottish universities to send representatives to a conference on this matter.

#### CARE OF THE FEEBLE-MINDED IN SCOTLAND.

At a meeting held last week, under the auspices of the Edinburgh Women Citizens' Association, an address on the permanent care of the feeble-minded was given by Dr. R. D. Clarkson, medical superintendent of the Royal Scottish National Institution, Larbert. Sir H. Arthur Rose, chairman of the General Board of Control for Scotland, who presided, said that this was one of the most important matters before it at the present time. Owing to the position of the national finances the Lunacy and Mental Deficiency Act of 1913, which was a statutory instrument of very great value, had been kept back from full fruition; but as soon as more freedom was given this particular work would receive the most sympathetic attention from the Treasury. Dr. Clarkson in the course of his address said that when he was appointed medical officer of the Institution for Mentally Defective Children at Larbert thirty years ago the general public took very little interest in the matter, but since then there had been a great change. Interest began in the schools, because defective children were a hindrance to their normal fellows. Social workers had also found that mental defectives played a great part in producing the problems with which they had to deal. He urged that all mental defectives should be registered, and should never be allowed to pass altogether out of control; also that farm-colonies should be established for them on the lines of one already started at Sandlebridge. At the close of the meeting the following resolution was unanimously passed: "That this meeting of Edinburgh citizens desires to express its earnest conviction that the time has come for immediate steps to be taken for the provision of homes throughout the country for the permanent care of the feeble-minded after school age." It was agreed to send a copy of this resolution to the Prime Minister, the Secretary for Scotland, the Board of Control, and the local members of Parliament.

### Ireland.

#### WOMEN'S NATIONAL HEALTH ASSOCIATION.

The annual meeting of the Women's National Health Association of Ireland was held at Ely House, Dublin. The Marchioness of Aberdeen and Temair presided, and said that it was intended to hold a conference during the coming autumn to which representatives of public bodies and voluntary associations interested in public health would be invited. The condition of the country, she said, had made it somewhat difficult to carry on the work of their branches, but good reports had been received from outlying districts. She submitted reports from Valentia Island, Waterford, Cork, Limerick, and Clare, all of which spoke of good welfare work being done.

Dr. Alice Barry submitted a report on the working of baby clubs and welfare societies in the city of Dublin. The mortality rate during the last year amongst children was 116 per 1,000, as compared with 163 per 1,000 a few years ago. Through the babies' clubs they had distributed 12,666 gallons of milk at an average price of 5d. a quart. The following resolutions were unanimously adopted:

(1) That the Council of the Women's National Health Association, feeling that there is urgent need for co-operation between the different bodies giving relief in the city of Dublin and in Ireland generally, request the Civics Institute to call a conference representing the different organizations, official and voluntary, interested in the subject, to discuss plans and form schemes whereby such work could be placed on a more satisfactory basis.

(2) That the Council approve of the principles and basis of the Children's Charter and direct the Sub-Executive Committee to examine its provisions with a view to adapting them to the needs of the children of Ireland, and to draw then the attention of the Free State Government to the Children's Charter with the request that it be adopted as the Government's policy regarding the position and claims of the children.

#### ST. ULTAN'S INFANT HOSPITAL, DUBLIN.

The foundation stone of a bacteriological laboratory, presented to St. Ultan's Infant Hospital, Charlemont Street, Dublin, by the Celtic Cross Society of Chicago, was laid last July by Mrs. MacWhorter, president of the society. The building, which is up to date in every particular and fitted with the most modern appliances, is now complete and was formally opened a short time ago. Miss Griffin, chairman of the Hospital Board, called upon Dr. W. M. Crofton to perform the opening ceremony and presented him with a golden key. One of the earliest patients admitted to the hospital, a sturdy lady of three years, presented Mrs. Crofton with a bouquet. Dr. Crofton made a short speech. Sir Edward Coey Bigger also spoke. Subsequently those present were entertained to tea by the board. In the evening of the same day a Pasteur celebration was held in the College of Physicians, when the president, Dr. M. F. Cox, was in the chair. Dr. Crofton gave a very interesting address on Pasteur, his life and work, and on some modern followers of his teaching. A vote of thanks to the lecturers was proposed by Dr. Ella Webb, chairman of the St. Ultan's Medical Board, and seconded by Dr. Kathleen Lynn, vice-chairman. The company were then entertained to tea, during which a short programme of music was gone through.

### England and Wales.

#### THE X-RAY DEPARTMENT OF THE MANCHESTER ROYAL INFIRMARY.

The new x-ray department of the Manchester Royal Infirmary, formally opened by Sir Humphry Rolleston last November during the joint meeting of the Röntgen Society and the Electro-therapeutic Section of the Royal Society of Medicine in Manchester, is now an important part of the hospital as an institution for the treatment of patients and the teaching of students.

When the Infirmary was opened in 1908 the accommodation provided for x-ray work was in the basement premises. The new department is now housed on the ground floor and there is sufficient space to allow each section of x-ray work to be conducted in its particular room. The money for the equipment was found by the generosity of a private donor. The protection of the walls—a matter of considerable importance—has been obtained by using commercial barium sulphate mixed with cement; it has been found quite satisfactory and very much cheaper than sheet lead. At present there is a surgical waiting list of about 1,000 patients, a large proportion of whom pass through the x-ray department before operation. In view of this high figure freedom from breakdown is essential, and Coolidge tubes working from transformers were installed as giving the highest reliability of output. The demonstration room is one of the features of the department. It is the teaching section and is provided with a lantern and viewing boxes and is used to demonstrate cases that have been previously examined in the screening room. In the screening room is a couch that can be tilted and is of assistance when palpating coils of intestine. A useful accessory is a Pirie retinometer, a device with three luminous points, the smallest of which should be visible before beginning to screen a patient. In the deep therapy department is one of the German outfits, and an English-made apparatus of the oil-immersed type. In the dark room the new Thorne-Baker green glass

has been fitted, which gives a plentiful slightly green light, which is apparently safe though it looks dangerous. It is a pleasanter light and has replaced the red lights previously in use.

A medical officer's room is provided where other members of the hospital staff may discuss their cases with the radiological staff. An office with a comprehensive filing and indexing system and plate-viewing room are other features of the department, and there is a workshop, fully equipped with tools for both wood and metal work, where minor repairs can be made. All the x-ray work is to be done on films, and an apparatus for making reduced prints (from wet negatives if necessary) is being fitted. All the cables for the department pass through two large switch boards and the connexions can be altered as required to balance the load equally between the two stations from which the department obtains its power. The work of installing the apparatus was entrusted to Messrs. Watson and Sons of London, and the new department may be regarded as a model of a modern x-ray equipment arranged to serve a large general hospital with an extensive out-patient practice. The department is probably the finest in the country and reflects the greatest credit on all those concerned in its establishment and equipment.

#### NEW MATERNITY HOSPITAL, LIVERPOOL.

An appeal for £100,000 was launched at a representative meeting at the Town Hall, Liverpool, on March 25th. The late Sir William Hartley gave £25,000, and had not the great war intervened the hospital would have been completed by this time. The present maternity hospital is utterly inadequate for the accommodation of patients and to meet the requirements of medical students. It originated in 1796 as a ladies' charity to provide attendance upon lying-in women in their own homes. In 1841 the Liverpool Lying-in Hospital was established, and in 1869 these two establishments were amalgamated. Under the Emeritus Professor of Obstetrics—Dr. Henry Briggs—during the past thirty-eight years the conjoint charity was developed to the great advantage of the medical students, whose practical training in midwifery was placed on a sound basis. Ante-natal care will become a department of midwifery and will be kept in view along with the post-natal treatment of the child. Infantile mortality has shown a great decrease in the last twenty years, but the mortality of parturients has remained the same. It is anticipated that a well equipped and properly staffed maternity hospital worthy of the city will reduce the maternal mortality. The number of lying-in women treated was 205 in 1894 and 1,200 in 1921. In addition to Sir William Hartley's donation, £7,000 have already been promised.

## Correspondence.

#### THE "UNIT" OF INSULIN.

SIR,—Dr. Cammidge, in your issue of May 5th (p. 787), expresses the opinion that "it is unfortunate that the Medical Research Council have seen fit to adopt a unit of measurement for insulin differing from that originally described by its inventors." Dr. Cammidge has not informed himself adequately, and his statement may contribute to that confusion, the possibility of which he rightly deplores. The unit has been changed, but not by the Medical Research Council; the change was made by the Toronto Committee, and the American firm working under their immediate authority. American insulin was to appear on the British market coincidentally with the first public offer of the home-made product, and uniformity could only be obtained by adopting the new unit, now current in all parts of the American continent. There is a minor inconvenience entailed, for those who had already in use a privately made supply, tested on the old basis. They have to bear in mind the fact that approximately three units of the current commercial product should correspond to one unit of what they had tested by the original Toronto indications. But Dr. Cammidge will, I think, agree that this is a small consideration compared

with that of the necessity for a world-wide uniformity of measurement, now and for the future.—I am, etc.,  
H. H. DALE.

Department of Biological Standards, Medical  
Research Council, May 7th.

#### THE EXAMINATION OF COLLOIDAL SOLUTIONS.

SIR,—Professor Clark, in his recent note (*BRITISH MEDICAL JOURNAL*, 1923, p. 731), is decidedly uncritical. He remarks that the colloidal ferrum Crookes which he has examined is very feebly acid in reaction, although mine was very faintly alkaline: at this point he ceases experiment and does not proceed to make his solutions feebly alkaline and then note whether the iron is precipitated. The iron is not thrown out of solution when the solution is made distinctly alkaline; this is one of the indications that it is in the colloidal state, and involves a simple test which he might readily have made. The addition of a minute amount of sodium hydroxide, sufficient to convert an N/300 acid solution to an N/300 alkaline solution, is required for the reversal of the reaction. My conclusion thus stands that colloidal ferrum Crookes is a preparation of a colloidal iron compound of the sugar type described by Graham in 1861.

Let me offer another simple demonstration of the colloidal state of the iron in the solution under discussion. The components capable of forming colloidal particles are the gelatin and the iron: the gelatin is present in the proportion of about 0.5 per cent. A gelatin solution of this concentration, examined in the ultra-microscope, shows a low concentration of very sluggishly moving particles; it shows a faint Tyndall effect—that is to say, a beam of light thrown through the solution appears as a but faintly illuminated track. On diluting the 0.5 per cent. gelatin fifty times, proportionately fewer but still sluggish particles are observed in the ultra-microscope, and the Tyndall effect is almost absent. The influence of the gelatin, as concerns the Tyndall effect—and this may be observed by anyone—and the ultra-microscopic appearances can thus be evaluated; the only other colloidal factor involved is the iron. Colloidal ferrum is so densely packed with colloidal particles as to be almost opaque to the beam of light which produces the Tyndall effect or is used in the ultra-microscope; but on diluting it fifty times a solution is obtained which shows the Tyndall effect very strongly, and gives in the ultra-microscope field a dense assemblage of colloidal particles in intense Brownian agitation. This result, the minute effect of the gelatin having been observed and allowed for, leaves it beyond doubt that iron in the colloidal state is responsible for the appearances noted.

It should be remarked that colloidal ferrum is a negative colloid—that is, the colloidal particles are negatively charged—whilst the colloidal iron solutions obtained by dialysis of ferric solutions or by prolonged boiling of ferric acetate solutions are positive colloids. The two types of colloids show very different properties, and, when mixed, mutually precipitate each other; thus, on mixing colloidal ferrum with a dilute solution of dialysed iron, practically the whole of the iron in both solutions is thrown out as a gelatinous precipitate. This is a further striking demonstration that the iron in colloidal ferrum is colloidal.

Although colloidal ferrum gives no colour directly with ammonium sulphocyanide, it gives the characteristic red colour with this reagent after addition of sulphuric acid; the colloidal ferric iron thus does not react with the sulphocyanide until it is actually dissolved in the sulphuric acid.

Professor Clark, whilst flying in the teeth of providence by his inadequate methods of showing that many well known colloidal solutions are not colloidal, expresses indignation at my statement that many, if not most, of the experimental results recorded in his earlier paper (*BRITISH MEDICAL JOURNAL*, 1923, i. p. 273) are erroneous and misleading; he complains that I produce no evidence to show that a single experimental fact stated in his paper is incorrect. I will rectify the omission, if one it be. He has told us that he finds a total of free and combined iodine in colloidal iodine aqueous (Crookes) of 0.04 per cent., and is supported in this by the analyst selected by the *BRITISH MEDICAL JOURNAL*. My analyses show that the solution contains almost exactly five times this percentage of iodine;

methods of work which lead to four-fifths of the iodine present being lost in an analysis provoke unkind remarks. But I do not agree that I have publicly ridiculed Professor Clark; I have merely shown that he has been led, by a too superficial study, to cast unfounded aspersions upon the characters of a number of thoroughly reputable colloids.

I add to the proof a note on Professor Sir William Bayliss's remark (BRITISH MEDICAL JOURNAL, 1923, p. 786) that collosol ferrum, diluted one hundred and thirty times, should appear to be crowded with colloidal particles; this is the case, both with the acid and the alkaline solution. Comparative observations made on 0.5 per cent. gelatin and collosol solution, each diluted one hundred and thirty times, indicate that these colloidal particles can only consist of a colloidal iron compound.

Dr. Dale's delicious sally will bear rereading when it is agreed that intelligent experiment proves what presumptuous experiment has denied—namely, that collosol ferrum contains an iron colloid. *Olim meminisse juvabit.*—I am, etc.,

Cambridge, May 3rd.

WILLIAM J. POPE.

We have referred this letter to Professor Clark, who writes:

SIR,—Sir William Pope in his first letter stated that collosol ferrum must be a colloidal preparation because it was alkaline and the iron was in the ferric state. This was an unfortunate argument because in the first place collosol ferrum is acid in reaction and the bulk of the iron is in the ferrous condition, and in the second place it is perfectly easy to make a dilute mixture of non-colloidal iron and gelatin which will give all the reactions for ferric salts, but which is not precipitated by moderately strong alkali. Sir William Pope's facts were wrong, and even if they had been right his argument was worthless.

I did most of the experiments described in Sir William Pope's last letter more than a year ago; it was Sir William Pope who stressed the importance of the reaction of collosol ferrum; I knew that the point was of no value as regards proving the colloidal or non-colloidal character of collosol ferrum; on the other hand, I thought the point of great value as a simple test of the care and accuracy with which Sir William Pope had prepared the strange attack he directed against me.

He says that the sample which he tested was alkaline, but it is certain that the vast majority, if not all the samples of collosol ferrum on sale are acid in reaction, and if Sir William Pope had taken the trouble to test a proper range of samples he would have saved himself from making a rather ridiculous mistake by basing sweeping conclusions on an atypical sample. As it is, his first letter consists of a rather unpleasant mixture of violent criticism and elementary mistakes. The facts stated in his second letter I believe to be correct, but some of the deductions are absurd.

I have dealt with the deductions regarding the reaction of the fluid. As regards ultra-microscopic examination, collosol ferrum is a turbid viscid fluid which usually deposits a considerable precipitate; naturally it is crowded with ultra-microscopic particles, but evidence is needed that these particles are composed of iron. Moreover, I am not prepared to say that no trace of colloidal iron is present; what I have said is that any fraction of the iron which may be in colloidal form is too small to be demonstrated by the usual tests of dialysis and ultra-filtration. As Sir William Pope states, it is quite true that collosol ferrum precipitates dialysed iron, but he has previously stated that the collosol contains 0.5 per cent. of gelatin, and he must surely know that gelatin precipitates dialysed iron, and that therefore this test is no proof that the collosol contains colloidal iron.

Sir William Pope finally turns to discuss my work on collosol iodine. I found that this substance contained one-quarter of the advertised amount of iodine, and was so surprised that I got the British Medical Association to have an independent analysis performed. This was done by Mr. Tickle, County Analyst for Devonshire, and his results agreed exactly with my analysis. While this work was proceeding, Messrs. Crookes apparently revised their ideas concerning the iodine content of collosol iodine, for while the label on the bottle still stated that it was an 0.2 per cent. solution, they stated in their literature that it contained

0.05 per cent. of colloidal iodine. Nearly three months after the publication of my paper Sir William Pope discovers that now this preparation contains 0.2 per cent. of iodine free and combined, and takes this as evidence that both I and an experienced analyst had independently made an identical series of gross errors in an extremely simple piece of chemical analysis. The analyses given in my paper stated correctly the composition of collosol iodine at the date when they were performed. I do not suggest that Sir William Pope's recent analysis is incorrect, but obviously it does not prove that the previous results were incorrect.

I am unwilling to take up space in the BRITISH MEDICAL JOURNAL with a personal matter, but I feel it is in the public interest to protest against the tone which Sir William Pope has seen fit to adopt in this controversy. At the request of the British Medical Association I examined certain commercial preparations, and some of the facts observed did not agree with the claims advertised.

Sir William Pope, for reasons unstated, has taken violent exception to my daring to criticize these commercial preparations, and has attacked my work with a violence that is unusual in scientific literature. Fortunately for me, the inaccuracy of his facts rendered Sir William Pope's attack ineffective.

Sir William Pope has stated that many if not most of my experimental results are erroneous, and that my methods are uncritical and inadequate. I do not claim infallibility, but Sir William Pope has not yet shown that a single one of my experimental results is incorrect.

Surely Sir William Pope must realize that sweeping charges like the above must be either fully substantiated or withdrawn.—I am, etc.,

London, W.C., May 8th.

A. J. CLARK.

#### CATGUT OR SILVER?

SIR,—With reference to your report of the proceedings of the British Congress of Obstetrics and Gynaecology held in Edinburgh, I beg to be allowed to amplify and so make clear the allusion to the "lively interchange of views on the best suture material for use in cases of vesico-vaginal fistulae" between Dr. Herbert Spencer and myself. I am sure no one more than Dr. Spencer would regret a misunderstanding in the matter.

I stood up for the use of catgut in surgery generally, as well as for vesico-vaginal fistulae in particular, as opposed to the sole use of silk, and in the case of vesico-vaginal fistulae of silver wire, advocated by Dr. Spencer. I confessed, as any honest gynaecologist must, that occasionally I had failed to close a high vesico-cervical or vesico-vaginal fistula at the first attempt—sometimes after others had tried—although I had succeeded at the second or, in one or two cases, at the third attempt, and that when I had failed I blamed myself and not the suture material. Dr. Spencer retaliated by saying that he had never failed to cure any case with silver wire; and the impression left on the Congress was that he had cured every case at the first attempt. This, indeed, is what your report—a perfectly accurate one—would lead anyone to suppose. Yet, although it appears that there would be no point in Dr. Spencer's statement unless he had meant this, I do not believe it possible that he intended to convey such an impression. I call attention to this misapprehension not to discredit Dr. Spencer in any way, but to prevent a false idea gaining acceptance through a misunderstanding of what Dr. Spencer meant when he said he had never failed to cure a case (that is, in the end)—namely, that silver wire may be looked upon as a corrective for imperfect technique in these difficult cases.—I am, etc.,

Liverpool, May 5th.

W. BLAIR BELL.

#### THE INFLUENCE OF INTESTINAL BACTERIA UPON THE THYROID GLAND.

SIR,—I make no claim to be the first to suggest that the intestinal bacteria interfere with the supply of amino-acids to the tissues, including the ductless glands. This was pointed out as early as 1905. Mr. Slesinger (April 14th, 1923, p. 659) in 1913 mentioned tryptophane as a possible precursor, not of thyroxin, as his letter seems to suggest, but of "the pigment in Addison's disease"; further comment is unnecessary, except to mention that the thyroid gland,

much less its active principle, was not even mentioned in his article. In an article, which I have ready for publication, I hope to throw some doubt on the supposition that tyrosin is the precursor of adrenaline.

Professor Kocher pointed out the dangers of giving iodine internally in quiescent goitre; I get good results with kerol, and I never give iodine now.

In conclusion I should like to remind optimistic surgeons that they have not yet convinced many eminent physicians (and a few surgeons) of the striking results of operative treatment of exophthalmic goitre.—I am, etc.,

Cardiff, May 2nd.

D. J. HARRIES.

#### SEPTICAEMIC INFECTION FOLLOWING OPERATIONS FOR APPENDICITIS.

SIR,—Mr. Herbert H. Brown in the *BRITISH MEDICAL JOURNAL* of April 7th, 1923, gives very interesting and instructive details of several cases of fatal septicaemia which have followed operations for acute appendicitis during the latter half of the first week, following acute clinical symptoms. I await with considerable interest further evidence of the value of the prophylactic serum of *B. coli* and *Streptococcus faecalis* he has had prepared.

As is pointed out in his article, the importance of the condition depends on the presence or absence of an effective bacterial immunity or resistance, and, as it is impossible to guess at the existence or absence of such, I would venture to suggest that considerable help may be obtained from a simple blood count estimation for evidence of an effective leucocytosis.

I have been in the habit of accepting such findings as indicating that prophylactic stimulation of further antibody response will probably be obtained from vaccine inoculation, particularly of the detoxicated variety, which doses may be repeated at twenty-four hour intervals. On the other hand, a low total count as regards white cells, or an actual leucopenia associated with an absence of relative increase of eosinophiles, I have considered contraindicates vaccine therapy in an acute case, but it suggests that help from serum therapy is possible.

The brunt of acute appendicular infectiveness, apart from lymphatic infection, must necessarily fall upon the portal system, which carries a large volume of infected blood by means of the portal vein to the liver. It is of special interest to note that Griffiths' very clearly points out the importance of such portal infection, as a cause not only of hepatitis, but also of pancreatitis. The type of cases that Mr. Brown so clearly cites seem to suggest this process.

I have for some time, in a somewhat empirical manner, suggested that vaccine or serum therapy in cases of acute abdominal infection should be reinforced by the administration of both bile and pancreatic extract, thereby enhancing the digestive metabolism of two most important organs, whose functional efficiency in an acute abdominal infection must frequently be very gravely embarrassed. So definite has been the result in several rather similar cases to those which Mr. Brown details, that I have ventured to write these points in case they may be of interest to others when confronted with this condition.—I am, etc.,

E. CRONIN LOWE, M.B.E., M.B., B.S.

Liverpool, April 13th.

#### STERILIZATION OF THE UNFIT.

SIR,—Dr. R. A. Gibbons believes that legislation for (1) eugenical sterilization and (2) marriage by State health certificate is "to be hoped for." There are good reasons why such legislation should not be hoped for. It is unlikely to come about, and it is undesirable that it should come about. The American mania for social legislation which so attracts Dr. Gibbons may better serve as a warning than as an example. It is strange, moreover, to find a member of the medical profession asking to have his present freedom controlled by the caprices of ignorant lay opinion.

Dr. Gibbons is ill informed concerning the evidence he brings forward. The Indiana law which he quotes at length became a dead letter in 1909, two years after it was passed,

<sup>1</sup> *Lancet*, February 10th.

and was finally declared "unconstitutional" in 1921; so also that of New Jersey. There never seems to have been any such law in Utah. That of New York was repealed in 1920, and quite time; "the history of this law," we are told, "is a record of incompetency and discredit; it has set back eugenical progress in the State's institutions more than ten years." But Kansas has sought to make up, for here a law was passed which would enable Dr. Gibbons not only to operate by law, but also to be fined one thousand dollars if he operated otherwise than by law, and, further, to be sent to prison for thirty days should he fail, or neglect, or refuse, to operate. This is the logical result of sterilization by law. Should Dr. Gibbons desire to emigrate to Kansas he will find further particulars in the latest and most authoritative work on this subject, Dr. Laughlin's *Eugenical Sterilization in the United States*, published last December by the Psychopathic Laboratory of the Municipal Court of Chicago, whence it may probably be obtained by qualified applicants.

In his thirst for sterilization laws Dr. Gibbons fails to make clear that they are quite unnecessary. There is nothing to-day to impede the spread of eugenical sterilization among us—with, of course, the consent of all responsible persons concerned—as introduced more than fifteen years ago in Switzerland. One would like to know why Dr. Gibbons, who has so much to say about the United States, fails to refer to the highly relevant fact that in the State of New York it has for more than ten years been the practice at the Buffalo State Hospital for Women to sterilize for eugenical reasons, with the written consent of the relations, but without reference to any law. That is the line of sound progress.

With regard to marriage by health certificate, and compulsory celibacy, while there is good reason for opposing procreation by unsuitable persons, there is no social reason for opposing marriage, but rather the reverse. In the early world marriage and procreation may have been the same thing; they have long ceased to be the same thing in the world in which Dr. Gibbons lives. In muddling them up Dr. Gibbons commits an unfortunate confusion, for not only is his anti-marriage propaganda bound to fail, but in the mere act of preaching it he is bringing ridicule and discredit upon the eugenical control of procreation.

There are in his paper various other misleading statements which may now be passed over. But in preparing the way for a measure so excellent as eugenical sterilization, and so certain to be eventually recognized in general medical and surgical practice, it is desirable to be cautious, accurate, and precise, leaving to opponents of the measure a total monopoly in arguments and statements that are otherwise.—I am, etc.,

London, S.W., May 7th.

H. HAVELOCK ELLIS.

#### HOSPITAL POLICY.

SIR,—Dr. Bernard Batt suggests that the policy of the Association regarding staff funds should be limited to patients on whose behalf there had been arranged some form of obligation through contributory schemes or payments by third parties; and that the Leicester resolution, or any modification of it, requiring an assessment of patients' own payments for staff funds, should be dropped. This proposition would, I think, prove unworkable, because it is an attempt to distinguish between patients who are not properly distinguishable. We are up against a similar difficulty in London. The Metropolitan Counties Branch Council, through a special committee, has been negotiating with the Hospitals Saving Association, for the improvement of the contributory scheme launched by it. By general consent the conditions of admission for out-patient treatment had been made the crucial point. We desire to bring these admissions within the policy of the Association, so that they should be mainly for consultative purposes. The sponsors of the scheme cannot accept this limitation of out-patient admissions. The secretary writes: "My chairman feels strongly that contributors cannot, and should not, be excluded from the out-patient facilities which are offered to non-contributors." As with this reform, so with staff funds—it must be assessment for all payments or for none.

On the point of Dr. Batt's challenge that the Council has not carried out the instruction of the Representative Body by securing information, I suggest that the report of the

Council is a fair statement of the facts governing its doings, and that the Representative Body will judge of its deeds whether they be good or evil.—I am, etc.,

London, W., May 3rd.

N. BISHOP HARMAN.

\*\* This correspondence cannot profitably be continued.

#### NOTIFICATION OF CONVICTIONS OF MEDICAL PRACTITIONERS TO THE GENERAL MEDICAL COUNCIL.

SIR,—Under this heading in the Report of Council (SUPPLEMENT to the BRITISH MEDICAL JOURNAL, April 28th, p. 141) there appears such an absolute travesty of my letter of July 1st, 1922, on this subject, that I ask, in fairness to myself, to be allowed to restate my case.

I am of opinion that convictions for trivial offences are not under the jurisdiction of Section 29 of the Medical Act of 1858. My legal adviser thinks with me. So, apparently, does the Registrar of the General Medical Council. I asked him if cases of breach of promise and bankruptcy were reported to the General Medical Council. This is his answer:

April 7th, 1922.

DEAR SIR,—In reply to your letter of the 6th inst., I have to say that Section 29 of the Medical Act of 1858 directs the Council to deal with two classes of offences—namely, convictions for felony or misdemeanour, or infamous conduct in a professional respect. Cases such as you mention would not as a rule come within either of these categories.—Yours faithfully,

(Signed) NORMAN C. KING.

I am left wondering by what process of legal reasoning failure to renew my dog licence (with conviction therefor) can be brought "within either of these categories." This despite the fact that Dr. Macdonald's mind seems to be satisfied on the point. (See SUPPLEMENT, May 5th, p. 169.)

"As a means of dealing adequately with real offenders" I suggested that real offences should be reported to the General Medical Council. Convictions for indictable offences by (1) prison governors in cases of commitment to prison, (2) metropolitan police where fine is imposed, and (3) chief constables in the country.

I suggested a different procedure in the matter of convictions in courts of summary jurisdiction before magistrates without jury. We have to convict in many instances where there is a small or technical offence. So I suggested that magistrates (who hear the whole evidence) should do the "sorting" for the General Medical Council. Real offenders would be reported to the Council by magistrates through their clerk. A system which necessitates that a doctor's conviction for having his chimney fired by his cook should be reported by the police and be "duly recorded" in London is an indignity to which no other profession is subjected, is a futility, entails a waste of stationery and official time, and is a trespass upon a medical man's civil liberty. "Hardship" is too dignified a term to be used in connexion with a procedure which is intrinsically paltry. I claim that these are not theoretical but plain and practical objections. And in the SUPPLEMENT of May 5th quoted above I am pleased to find an ally on the Council in Sir Jenner Verrall. He seems to deprecate the reporting of "convictions of practitioners even for the most trivial and technical offences," but fathers the blame upon the Home Office. I have listened, during the last nine years, to many cases of disputed paternity and I was careful to obtain exact evidence. The General Medical Council is the admitted author of the procedure.—I am, etc.,

Stockport, May 6th.

J. M. BRENNAN.

#### THE COOLIDGE X-RAY TUBE.

SIR,—The remarks of Dr. W. M. Robson on the subject of Coolidge x-ray tubes in your issue of April 21st (p. 699) are of great interest to us as distributors of the tubes in this country.

We feel that his unfortunate experience must be somewhat isolated as many thousands of Coolidge x-ray tubes are in daily use, the majority of which, to judge by the very small number of complaints we receive, are in the hands of satisfied users. The manufacture of the Coolidge tube is

admittedly a difficult process demanding the most meticulous care and supervision, and it is only by exercising systematic control and testing at every stage in the manufacture that a tube is obtained as nearly perfect as it is humanly possible to make it.

Dr. Robson pays what is, to our mind, a wonderful tribute to the Coolidge tube when he states that he has known Coolidge tubes which will run "for one and a half to two hours or longer at a parallel spark-gap of 10 in. and with a current of 10 milliamperes passing through the tube, without causing any trouble or anxiety." No Coolidge tube has yet been placed on the market which has been designed to work under conditions as severe as these, and the fact that he has found tubes which could be overrun to this extent without immediate damage is very gratifying evidence of the large factor of safety which we are glad to feel is commonly associated with the Coolidge tube.—I am, etc.,

GEOFFREY PEARCE,  
Managing Director, Watson and Sons  
(Electro-Medical), Limited.

London, W.C., April 27th.

#### "QUAIN'S ANATOMY."

SIR,—I have had such a curious experience in connexion with the purchase of a copy of *Quain's Anatomy* that I think it would be well to communicate it to the readers of the JOURNAL. It is about three years since a lady, who wished to present a friend of hers with a good work on anatomy, asked me to recommend some particularly good work. I said that I was brought up on *Gray's Anatomy* myself, but that *Quain's* was generally considered the foremost work on anatomy in the English language. So she ordered a *Quain* from the bookman here in Clifton. It was duly delivered and paid for. Some considerable time afterwards she learnt that the edition was not complete. She went to the bookseller—he said he was sorry, but did not know it was incomplete. I then stated the circumstances to the publishers, and they were unable to give me any information as to when the missing volume of the book would be ready, disclaiming all responsibility for the delay, which was apparently due to the author of the missing volume not having the material ready for publication and issue along with the other volumes. Then I wrote to the principal editor, and he expressed regret that he didn't know when the new volume would be ready, but that "doubtless when it did appear I would be able to get a copy." Of course the recipient of the gift has had to get along by using another work treating of the blood vessels. But to me it seems a most extraordinary business transaction, and has certainly proved to be a very unsatisfactory one.—I am, etc.,

J. SMYTH, M.D.,  
Colonel I.M.S. (ret.).

Clifton, Bristol, April 17th.

### Universities and Colleges.

#### UNIVERSITY OF OXFORD.

*Degree Days.*—Degree days in the present term are Saturday, May 26th, Thursday, June 21st, Thursday, June 28th, Saturday, July 7th.

*Rolleston Memorial Prize.*—The next award of the Rolleston Memorial Prize will be made in Trinity Term, 1924. The prize is now of the value of about £100, and is awarded for original research in any subject in animal and vegetable morphology; physiology and pathology; and anthropology. Candidates must forward their Memoirs to the Registrar of the University of Oxford before March 31st, 1924. The memoirs may be printed, type-written, or in manuscript; should be inscribed "Rolleston Memorial Essay," and should bear the name and address of the author. No candidate will be eligible (1) who has not either passed the examinations for the B.A. degree or the B.M. degree at Oxford, or for the B.A. degree or the M.B. degree at Cambridge, or been admitted as a candidate for the degree of B.Sc. at Oxford, or as an advanced student for the degree of B.A. at Cambridge; (2) who has exceeded a period of six years from attaining one or other of these qualifications, or from his attaining the first of such qualifications, if he attained more than one; (3) who has exceeded ten years from his matriculation. (Reference *Oxford University Gazette*, April 26th, 1923.)

At a congregation held on May 3rd the following degrees were conferred:

D.M.—E. H. Culver (in absence).  
B.Sc.—B. W. Williams.

## UNIVERSITY OF CAMBRIDGE.

*Course in Psychological Medicine.*

A short course for the diploma in Psychological Medicine has been planned to be held in Cambridge from July 10th to August 17th. The subjects covered will be the physiology and anatomy of the nervous system, psychology, psychopathology, mental deficiency and practical psychiatry. The fee for the full course will be twelve guineas, but attendance at separate lectures can be arranged. Applications to attend the course should be sent to the Secretary, D.P.M. Committee, Psychological Laboratory, Cambridge, before June 7th. If a sufficient number do not apply the course will not be held.

At a congregation held on May 5th the following degrees were conferred:

M.D.—T. J. H. Hoskin.  
M.B.—A. G. F. McArthur, H. R. Bickerton.  
M.B., B.Ch.—C. B. S. Fuller.

## UNIVERSITY OF LONDON.

## PRESENTATION DAY.

*Capping Ceremony.*

The ceremony of presenting new graduates for degrees was held on May 3rd in the Albert Hall, which was well filled. Before the presentation the Principal Officer, Sir Cooper Perry, read his report on the work of the University during the year 1922-23. The total number of graduates admitted was 8,498, as compared with 3,652 in the last year before the war, and 7,092 in 1921 and 1922. Of those admitted last year 6,746 came in through the ordinary matriculation examination, for which, it would appear, there were nearly 20,000 candidates. The number of degrees and diplomas granted was 2,422, as compared with 1,301 nine years ago, and 2,093 last year. Reference was made to the Rockefeller gifts to University College and University College Hospital Medical School, and to the approaching visit of the King and Queen to lay the foundation stones of the obstetric hospital and nurses' home, and to open the new building for anatomy, embryology and histology. Reference was also made to the other gift of the Rockefeller Trustees, which made possible the erection of buildings for a school of hygiene.

After the capping by the Vice-Chancellor, who, owing to the large number of new graduates, was assisted by two other members of the Senate, the Vice-Chancellor read his "charge," which he described as a word of counsel from an older graduate to his younger comrades. A university degree, he said, was at once an end and a beginning; the end of three or four years of study and intellectual discipline, and the beginning of a larger discipline through contact with a larger world.

*Service at Westminster Abbey.*

The annual service for members of the University held at Westminster Abbey was attended by a large number of graduates of both sexes wearing academic robes. The Dean of Westminster read the lessons, and the Dean of St. Paul's preached the sermon, from the words "There is nothing new under the sun," and "I will make all things new." In the course of his sermon he said that a well ordered state must have regard for proportion between social service and the remuneration for such service, with perhaps a reasonable limit to the extent to which any man might appropriate to himself the results of the labours of others. It would be necessary to get rid of the conception of "a gentleman" as a man who did no work and had plenty of money to throw away. If the country was to recover we must all do more work than we fancied we were paid for doing.

*Graduation Dinner.*

A graduation dinner was held in the evening at Grocers' Hall, when the Vice-Chancellor was in the chair. The toast of the University of London and the new graduates was proposed by Sir Robert Blair, Education Officer to the London County Council. The University, he said, had been a pioneer in research and the extension of knowledge and the first to open its doors to women. Its fees, however, were higher than those of Scottish, Irish and Welsh Universities. If the cost of university education in England was kept too high it would be impossible for the poor man, the small tradesman, and particularly the artisan, to send his children to the universities. In the London area there was a great mass of unorganized knowledge ready to be organized and classified, and if there was still closer co-operation with the local education authorities the destiny of the University would reach a far higher point than anybody now could imagine.

The Vice-Chancellor, in reply, referred to the suggested division of the University into two, or, as some logically minded critics had suggested, into twelve or more universities, and said that it was the opinion of the University itself, as it had been of successive Royal Commissions, that there should be one University only in London. He mentioned the great assistance the City of London had given to the establishment of degrees in commerce as a good omen, encouraging the belief that the City would associate itself more closely with the work of the University. London had always been a poor man's University, the fees of the different colleges varied, but they represented only a small proportion of the cost of the education provided. The County Council and some of the City Companies offered scholarships, but there was room for more not only to enable poor students to enter the University but also to enable worthy students to remain after graduation for post-graduate and research work. Passing to the discussions which have occurred about the new site for the University, Mr. Waring

said that there was only one site within the realm of practical politics, a site of about eleven acres in Bloomsbury offered by the Government subject to certain conditions on both sides. The terms of the removal of King's College from its valuable site in the Strand would be a matter of negotiation between the Government, the Council of King's College, and the Senate of the University. Both the University and King's College would retain their present sites until the new buildings were ready for occupation free from debt; probably about six acres would be allotted for the University buildings and about four for the new building of King's College; plans for both had been prepared and were under consideration. In addition to the two great Colleges, University and King's, there were incorporated in the University 34 schools or colleges, including the medical schools. The number of students in all the institutions was estimated at about 20,000, of whom about 8,880 were sitting for degrees in the University. The teachers numbered over 1,000. Although the great bulk of the university students were preparing for the first degree London was gradually being recognized as pre-eminently the centre for post-graduate research, and for higher studies. The establishment soon after the war of the degree of Ph.D. in order to encourage post-graduate work and meet the needs of students coming from overseas, had fully justified itself; over 400 students had registered themselves for the degree. Sir William Collins, in proposing the toast of the guests, said that the University of London was not merely imperial but international. It had recognized students, the majority of them he believed Americans, from foreign universities, some of whom had received its highest degrees. In conclusion he expressed the pleasure with which the graduates welcomed the French Ambassador and representatives of the French universities. The toast was acknowledged by Viscount Burnham.

The Vice-Chancellor said that he had received a message of good wishes from the Chancellor, who was unable to be present owing to the state of his health.

## ELECTIONS TO THE SENATE.

Dr. R. A. Young has been elected a member of the Senate by Convocation in the Faculty of Medicine and Sir Sydney Russell-Wells, M.D., M.P., is one of those elected in the Faculty of Science. Lord Dawson of Penn and Dr. R. L. Eason, C.B., represent the Faculty of Medicine, and Sir William Collins, M.D., the London County Council. Mr. G. Leslie Eastes desires to thank those members of Convocation who recorded their votes for him and adds that only 30 per cent. of the electorate voted.

## ROYAL COLLEGE OF SURGEONS OF ENGLAND.

At a meeting of the Council, on April 12th, diplomas of membership were granted to the following:—

B. Bourke, \*Eddie D. Fenwick, \*Marjorie A. Godfrey, \*N. R. Mucadam.

\*Under the Medical Act, 1875.

## ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

At a meeting of the Royal College of Physicians of Edinburgh on May 1st, when Sir Robert Philip, President, was in the chair, Dr. Henry George Masson was elected to the Fellowship of the College; and Drs. James Davie Gilruth and William Arnott Dickson were admitted to membership. The College re-elected Dr. William Russell as its representative in the General Medical Council for a further period of five years. The Freeland Barbour Fellowship for original research was awarded to Dr. James Walker Dawson. The gift by Lord Polwarth of an autograph letter by Edward Jenner dated 14th September, 1799, was received.

## ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

J. V. DHURANDHAR, M.B., B.S. (Bombay), having passed the requisite examination, has been admitted to the Licence in Midwifery.

## The Services.

## DEATHS IN THE SERVICES.

LIEUT.-COLONEL ARTHUR WILLIAM DAWSON, Bengal Medical Service (retired), died at Grange Park, North London, on March 7th, aged 64. He was the son of Dr. Thomas Dawson of Liverpool, born on February 11th, 1859, and was educated at Liverpool and at King's College, London. He graduated M.B. at Durham University in 1884 and M.D. in 1892, also taking the M.R.C.S. and L.R.C.P. Lond. in 1885. He entered the I.M.S. as surgeon on April 1st, 1886, became lieutenant-colonel after twenty years' service, and retired on July 19th, 1917. He spent his whole service in military employment, and for many years was medical officer of the Sappers and Miners stationed at Kurki. He had a long record of war service: North-East Frontier of India, Chin Lushai, 1889-90, medal with clasp; North-West Frontier, Hazara, 1891, clasp; Chitral, 1895, relief of Chitral, medal with clasp; Tirah, 1897-98, actions of Dargai and of the Sampagha and Arhanga Passes, operations at and around Dwatoi, and operations in the Bara Valley, two clasps; China, 1900, medal; Tibet, 1903-4, medal; and North-West Frontier, 1903, operations in the Momand country, medal. During the recent war he was in medical charge of the Indian hospital ship *Glenart*.

*Castle*, and was on board when she was in a collision on her first voyage, but had left her before she was finally sunk, with great loss of life, in the Bristol Channel.

Surgeon Alexander William MacLeod, R.N.(ret.), died at Great Yarmouth on April 9th. He was the elder son of the late Inspector-General William MacLeod, M.D., C.B., R.N. After taking the diplomas of L.R.C.P. and S. at Edinburgh in 1877, he entered the navy as surgeon in the same year, but retired after a few years' service in the same rank.

## Obituary.

CHARLES KILLICK, M.A., M.D., B.CH.CANTAB.,  
F.R.C.S.ENG.,

Honorary Surgeon, Royal Eye and Ear Hospital, Bradford, and  
Honorary Ophthalmic Surgeon, Bradford Royal Infirmary.

THE medical profession not only of Bradford but also of a much wider area has to deplore the sudden and tragic death at the age of 48 of Dr. Charles Killick. Apparently in normal health, he infected his finger while examining an ophthalmic patient and died within nine days of septicaemia. Born near Bradford, a member of a well known professional family, he received his medical education at Cambridge University. After taking his arts degree with honours in the natural science tripos, he gained a university scholarship at St. Mary's Hospital, London. His bent—ophthalmological—almost from the first led him to take up that branch of surgery, and he spent many years in Maidstone in ophthalmic practice and as honorary surgeon to the Kent County Ophthalmic Hospital. In spite of his success there he felt that Kent was not sufficiently bracing for his children, and he returned to Bradford, becoming honorary ophthalmic surgeon to the Royal Eye and Ear Hospital. He was a life member of the Société Ophthalmologique de France, a member of the council of the Ophthalmic Section of the Royal Society of Medicine, a member of the Ophthalmological Society of Great Britain, and a member of the Bradford Division of the British Medical Association. He was a frequent contributor to the medical journals; his chief hobby, indeed, was the translation of French and other foreign ophthalmic works. He greatly preferred literary and scientific studies to outdoor recreation. Of recent years he became interested in freemasonry, and obtained in a very short time an astonishing mastery of its ritual. His geniality and mental alertness as well as his great medical abilities made him universally popular in Bradford, and his early death is a severe loss to the profession. Great sympathy is felt for his widow and young children.

## Medical News.

AN Emeritus lecture will be delivered at the Middlesex Hospital Medical School by Sir John Bland-Sutton, LL.D., on Tuesday, June 5th, at 3 p.m.

MEMBERS of the Association who desire to take part in the discussions to be held in the Section of Diseases of Children at the Annual Meeting of the British Medical Association at Portsmouth next July are requested to communicate with Dr. R. Hamer Hodges, 93, Victoria Road North, Southsea. On Thursday, July 26th, the discussion will be on acidosis and alkalosis in children, and on Friday, July 27th, summer diarrhoea will be discussed.

THE annual dinner of the Federation of Medical and Allied Services will be held at the Langham Hotel, Portland Place, W.1, on Tuesday, May 29th, at 7.15 p.m., and not on May 23rd as previously announced. Sir Berkeley Moynihan, the president, will preside, and the chief guest will be the Right Hon. Neville Chamberlain, Minister of Health.

DR. C. K. CLARKE of Toronto will deliver the Maudsley lecture before the Medico-Psychological Association of Great Britain and Ireland in the Barnes Hall of the Royal Society of Medicine on Thursday, May 24th, at 3 p.m. Dr. Clarke will be entertained to dinner on the same evening. The quarterly meeting of the Society will be held at 11, Chandos Street, W.1, at 2.30 p.m. on the same day.

It is hoped that the Duke of York will be able to lay the corner stone of the new Nurses' Home of the Liverpool Royal Infirmary on July 25th.

At a meeting of the Medico-Legal Society on Tuesday next, May 15th, at the house of the Medical Society of London, a discussion on the Mental Treatment Bill, 1923, will be opened by Mr. A. H. Trevor, B.A. The chair will be taken at 8.30 p.m.

THE Infants' Hospital, Vincent Square, Westminster, has arranged a course of lectures, to be delivered by members of the medical staff during May and June at 8.45 p.m., on the diseases and treatment of infants. The first lecture of the series will be given by Dr. Eric Pritchard on Tuesday, May 15th, on the principles of infant feeding, and the second by Dr. Helen Mackay, on the treatment of nutritional disorders in infancy, on Wednesday, May 23rd.

WHEN the proposal was first made by the Inchcape Retrenchment Committee a couple of months ago we pointed out the strong objections there were to the abolition of the appointment of Public Health Commissioner with the Government of India. The *Times* correspondent, in a telegram from Simla on May 6th, states that the proposal has been abandoned.

DR. RUSSELL JOHN REYNOLDS has been appointed Honorary Adviser in Radiology to the Ministry of Pensions.

THE summer dinner of the Glasgow University Club, London, is to be held at the Trocadero on Friday, June 1st, at 7.30 p.m., when the Lord Rector, the Earl of Birkenhead, will preside. Any Glasgow University men who, though not members of the club, would like to attend, are invited to communicate as early as possible with the honorary secretaries, 1, Harley Place, N.W.1.

THE Ministry of Pensions announces that meetings of the Standing Joint Committee for Ex-Service Questions were held on April 27th. At the meeting of the Other Ranks Panel over which Major G. C. Tryon, M.P., Minister of Pensions, presided, it was stated that the special institution provided in the south of England for the separate treatment of insane ex-service men was now occupied by 50 patients and the number would shortly be doubled. The patients had been chosen from amongst those in county and borough asylums. Of one hundred relatives approached on the matter nearly half objected to the transfer of patients to a distance, being satisfied with the treatment given in their own county and borough asylums. Representatives of the British Legion expressed appreciation of the efforts made by the Ministry of Pensions to obtain separate treatment. Other subjects brought before the meeting included service disability awards, the care of motherless children, parents' need pensions, and repairs to artificial limbs.

A NEW course of post-graduate lectures free to medical practitioners commenced on May 3rd at the Hospital for Sick Children, Great Ormond Street, W.C.1, and will be continued on succeeding Thursdays at 4 p.m. up till and including July 12th.

THE Ministry of Health has issued a list (London: H.M. Stationery Office, price 3d.) of approved sanatoriums and other residential institutions for the treatment of persons suffering from tuberculosis and resident in England and Wales, with the names of the administrative counties and county boroughs in which the institutions are situated and the date on which approval expires.

DR. W. M. FRAZER and Dr. I. D. EVANS of Gray's Inn were called to the Bar on April 25th.

DR. G. M. THOMPSON, on the occasion of his retiring from the post of medical officer of Bellaghy dispensary district, which he had held for forty years, has been presented with an Overland Sedan car and an illuminated album containing the names of 700 subscribers. Mrs. Thompson was on the same occasion presented with a silver salver.

THE Southend Doctors' Cricket Club has a vacant date on Wednesday, August 1st, 1923. They will be very glad to arrange a match on that day against a team of doctors, and to entertain the players and their friends to tea after the game. Any doctor interested is asked to communicate with the Honorary Secretary, Dr. A. W. Holthausen, 583, London Road, Westcliff-on-Sea.

A LECTURE on the psychology of epilepsy will be given at the house of the Royal Society of Medicine on Thursday, May 24th, at 5.15 p.m., by Dr. E. D. Wiersma, professor of psychiatry and neurology in the University of Groningen. The chair will be taken by Dr. Robert H. Cole, physician for mental diseases to St. Mary's Hospital. The lecture is one of the course in advanced psychiatry organized by the University of London. Admission is free without ticket.

THE house and library of the Royal Society of Medicine will be closed from Saturday, May 19th, to Monday, May 21st, both days inclusive.

THE Ingleby lectures before the University of Birmingham will be delivered by Dr. Harold Black on May 30th and June 6th at 4 p.m.; the subject selected is the investigation of the alimentary tract by  $x$  rays. Members of the medical profession are invited to attend.

WE mentioned a few weeks ago that the Section of Otolaryngology of the Swedish Society of Physicians had invited some representatives from this country to visit Stockholm and to take part in certain meetings there. The British party is to arrive in Stockholm on the morning of Friday, May 18th, and will be entertained by Professor and Mrs. Holmgren in the evening. On the following morning Professor G. Forsell will give a demonstration at the Radium Institute, and in the afternoon there will be a meeting in the rooms of the Swedish Society of Medicine, when papers will be read by Dr. Logan Turner, Dr. Brown Kelly, Dr. de Kleyn, Professor Bárány, and others. In the evening the Section for Otolaryngology will entertain the foreign guests at dinner. On May 20th the party will pay a visit to Upsala, and on the following day will go sightseeing in Stockholm. On the evening of May 22nd there will be a final meeting at the house of the Society of Medicine, when papers will be read by Sir StClair Thomson, Professor H. Burger and Dr. Arthur Cheate.

THE third annual congress of German oto-rhino-laryngologists will be held at Kissingen next week (May 17th to 19th), when the following subjects will be discussed: (1) Operations on the accessory sinus, introduced by Hajek of Vienna, Halle of Berlin, and Manasse of Würzburg; (2) treatment of chronic tonsillitis, introduced by Dietrich of Cologne, Kummel of Heidelberg, and Schlemmer of Vienna.

THE Fourth International Neurological Congress will be held at La Salpêtrière in Paris on June 8th and 9th, when the subject for discussion will be compression of the spinal cord. The pathological anatomy and pathogenesis will be dealt with by Sir James Purves-Stewart and Dr. George Riddoch of London, and the pathological physiology, clinical symptoms, and treatment by Dr. C. Foix of Paris. Further information can be obtained from the General Secretary, Dr. H. Meige, 35, Rue de Grenelle, Paris.

THE Dutch Orthopaedic Society will celebrate its twenty-fifth anniversary in the hall of the University at Amsterdam on May 25th and 26th, under the presidency of Dr. Murk Jansen, when addresses will be delivered by Sir Robert Jones, Professor Adolf Lorenz, Dr. Albee, Dr. Calot, Dr. Spitzky, and Dr. Putti.

THE Cairo correspondent of the *Daily Telegraph* states that during the last week in April one hundred cases of plague were reported for the whole of Egypt. No cases were reported at Cairo; in Alexandria there was one case, and in Port Said two. The situation is reported to be more or less normal except at Girga and Assiout, where the infection is spreading. The disease is chiefly of the bubonic type.

THE seventh All-Russian Congress of Bacteriology, Epidemiology, and Public Health will, it is announced, be held at Moscow from May 22nd to 28th, when the following subjects will be discussed: (1) Immunity, serotherapy, vaccine therapy, chemotherapy, and diagnosis; (2) bacteriology and epidemiology of the prevalent infectious diseases in Russia; (3) disinfection and destruction of rats and insects; (4) organization.

THE total receipts of the United Hospital Fund of New York for the year ending June 30th, 1922, amounted, according to the annual report, to 585,557 dollars, as compared with 710,773 dollars in the previous year. In 1919-20 and 1920-21 there were "high pressure" hospital campaigns; the receipts in 1918-19 amounted to 221,535 dollars only, but this was the highest amount received down to that time. At the annual distribution of funds a sum of 525,000 dollars was allotted in amounts varying from 37,000 dollars to 1,000 dollars among 56 hospitals, comprising 18 general hospitals, 10 hospitals for women and children (including maternity hospitals), 11 special hospitals (including orthopaedic, eye, ear and throat, skin and cancer, and neurological hospitals), 6 hospitals for convalescents and chronic cases, and 11 hospitals in Brooklyn. The United Hospital Fund of New York was organized in 1879, and the receipts for the year 1879-80 were 26,455 dollars, distributed among 19 hospitals. All hospitals sharing in the fund are required to submit an annual statement on a uniform form showing in detail the work, income, and expenses for the preceding year. Any hospital in Greater New York may become a member of the United Hospital Fund after recommendation by a committee on admissions as to its equipment and management, and election by the Board of Trustees, provided that it is duly incorporated, has had for three years at least thirty-five ward beds, and has given during the same period not less than 5,000 days of free service each year.

IN the six Swiss universities there are at present 1,451 medical students, of whom 187 are women; among them are 231 foreigners, including 49 women.

## Letters, Notes, and Answers.

*As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.*

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

IN order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology, Westrand, London*; telephone, 2630, Gerrard.

2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard.

3. MEDICAL SECRETARY, *Mediscera, Westrand, London*; telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate, Edinburgh*; telephone, 4361, Central).

### QUERIES AND ANSWERS.

"N." asks if any reader can suggest a successful remedy for black tongue.

WHOOPIING-COUGH.

DR. THOMAS CARRUTHERS (Kilbarchan, Renfrewshire) writes to point out that Dr. Midelton's note of April 28th (p. 746) contains no statement as to the period in the disease at which the treatment was begun; the whoop may go on for a long time by a sort of habit spasm. Dr. Carruthers adds that in a disease so variable both in duration and intensity "controls" are necessary.

### INCOME TAX.

"ANTHONY" took over a practice on March 31st, 1921. The inspector of taxes asserts that his predecessor's figures for past profits of the practice appear to have been inaccurate, and that as the correct figures cannot be ascertained he proposes that the practice shall be assessed for 1921-22 and 1922-23 on the first accounts of the new proprietors for the period to March 31st, 1923.

\* \* If, as seems to be clearly the case, "Anthony's" predecessor was doing badly, the inspector's proposal is unfair, as its adoption would deprive our correspondent of the benefit of the three years' average to which he is legally entitled. The impracticability of showing what were the past profits is, of course, a serious difficulty, but assuming that it can be shown that for specific causes the 1921-1923 earnings of the practice were greater than the 1918-1921 profits, it ought to be possible to come to some arrangement with the inspector to agree on an assessment on the three years' average basis, which would be less than the 1921-23 profits, though perhaps greater than the amount first claimed. Failing such agreement, the matter might be dealt with by the Commissioners on a personal appeal from the assessment when made; if all the ascertainable facts were put before them, they would, no doubt, give a decision which would be a reasonable compromise between the two figures at present in the field.

"A. B." holds an appointment under a local authority from whom he receives a rate per mile to cover all running expenses, repairs, depreciation of his car. When he renewed his car he found that the mileage allowance has not been sufficient to recoup him for the loss of capital value of his old car. Can he claim any special allowance from income tax?

\* \* He is entitled to allowance of expenses incurred wholly exclusively and necessarily in the performance of his duties. It may be that some of the expenses charged in "A. B.'s" car account might have to be reduced on account of private as distinct from official use of his car, but, apart from that, there is a difficulty arising over the introduction into the Statute of the word necessary. The local authority by which "A. B." is employed presumably decided on the rate per mile as sufficient for the type of car "necessary" for the work, and "A. B." may very well be open to attack—as regards any special claim—that the loss arises through his use of a car which was superior to

that "necessary," in power, type, or accommodation. One or two of "A. B.'s" figures—that is, the "purchase price of car £570" and "selling price £225"—differ from those in his covering statement, but the above considerations apply in any case.

"J. S." has to live in a house by virtue of his appointment as M.O. to a charity; he may not sublet it and must give it up on relinquishing his appointment; he has to pay for the internal repairs of the house but not for the rates.

\* \* On the facts the charity appears to be the statutory occupier of the premises, and the annual value forms no part of the "income" of "J. S.," inasmuch as the benefit of residence is not convertible into money (*Tennant v. Smith*).

### LETTERS, NOTES, ETC.

#### THE UNPLEASANT TASTE OF POTASSIUM BROMIDE.

DR. S. P. CASTELL (London, N.6) writes to suggest that the difficulty about the taste of potassium bromide can be avoided by using sodium bromide, the taste of which is the same as that of common salt. Thirty grains in a cup of meat extract, he says, is scarcely detected. Dr. Castell adds that a patient who persistently refused potassium iodide in various disguises took sodium iodide without any suspicion.

#### DE MORGAN'S SPOTS AND MALIGNANCY.

DR. GEO. A. PEMBERTON WRIGHT (Southampton) writes: Recently, on examining a man suffering from bronchitis, I noticed some twenty of the reddish or crimson raised spots known as De Morgan spots scattered all over the skin of the chest, with four fairly large ones within a radius of 1 inch from the region of the ensiform cartilage. I have noticed many cases before, but never so many spots on one man. In most of the cases noticed (over fifty in number) the spots have been single, rarely two or three together, and the sites have been in order of frequency: (1) Area of ensiform cartilage. (2) In the nipple line, mostly within a radius of a couple of inches or so from the nipple itself. (3) Near the umbilicus. I have not noticed them in other parts of the body. We were taught that these spots were related in some way with malignant disease and were found generally on persons suffering from such maladies. Of the cases that I have noticed, only one—a woman, aged 56 years—suffered from malignant disease. She had cancer of the stomach and one De Morgan spot near the left nipple. The last case I have noticed—the man with twenty spots on his chest—is very healthy excepting the temporary bronchitis. It seems unlikely that there really can be any connexion at all between the appearance of these spots and malignant disease. There must be some other explanation, and I should be very interested to hear it.

#### SERUM BY THE MOUTH.

DR. T. M. ALLISON (Newcastle-on-Tyne) writes: Some time ago in the BRITISH MEDICAL JOURNAL there were recorded some laboratory experiments made at Cambridge on guinea-pigs, throwing doubt on the efficacy of antidiphtheria serum when administered by the mouth. The method in human beings in my experience during the last thirty years has given excellent results, and the following letter from a practitioner in East Kew, Victoria, Australia, is interesting as confirming that experience.

"Dear Sir,—With reference to your letter in the BRITISH MEDICAL JOURNAL of November 18th last, it might be of interest to you to know of another Australian experience. Some years ago I was in a health resort in the mountains near Melbourne, and as an epidemic of diphtheria broke out it became necessary to stamp out the outbreak. I considered the plan of swabbing all the school children, but thought I would try a clean sweep as the easiest and most effective method, and this took the form of administering of antidiphtheria serum by the mouth. In all about one hundred and seventy State school children and about fifty convent school children were treated. The children were given about one thousand units each of the antidiphtheria serum by the mouth from a small china egg-cup; about one dozen egg-cups were used, and sterilized by boiling after each batch of one dozen children received their dose of the serum. Each child was told to sip the serum and hold it underneath the tongue for a minute or more before swallowing it. The local action of the serum in the mouth, throat, and tonsils may have been the chief factor, but after dealing with all these children in one afternoon there were no further cases of diphtheria, and no possibility of anaphylaxis if the serum had to be injected at a later date.—R. A. PARKER."

#### TREATMENT OF ACNE VULGARIS.

DR. M. AZER (Cairo) writes to recommend the following method for treating obstinate cases of acne vulgaris. All the cases treated were of over a year's duration and other treatments, including that by auto-vaccines, had failed. He gives an intramuscular injection of colloidal manganese every fourth day, one teaspoonful of levure de bière in water before every meal, and the following lotion dabbed on the parts night and morning: Pulv. calamin. 5 ij, pulv. zinci oxid. 5. ij, pulv. tragacanth 5 j, sulphur ppt. 5 ij, aq. calcis 5 ij, aq. rosea ad 5 viij. Dr. Azer gives a brief history of four cases: (1) A lady in whom the face, chest, and back had been affected (comedo and pustular stage) for two years; after seven injections great improvement was

noticed. (2) A policeman in whom the distribution was the same; he had suffered for one year; after six intramuscular injections he recovered. (3) A student with lesions on the face in the pustular stage; he had suffered for fourteen months and improvement followed eight injections. (4) A student with lesions in the pustular and comedo stage on face, back, and chest for one year, was somewhat improved after six injections.

#### A CAUSE OF LIFELONG HEADACHE.

DR. REGINALD COCK (London, E.2) writes: About two years ago a patient of mine, G., aged 74 years, wrote me the following letter:

"Dear Sir,—As I have often been under your kind treatment for my health and the bad pains and the dreadful sensations in my head through losing my hair when a child, for which there was no apparent cause whatever, not even illness—which has always been a mystery—I shall indeed feel extremely grateful if you will open my head after death, should you outlive me, whereby you, perhaps, may be able to find out the cause of my poor head being so greatly afflicted, causing me at times such acute suffering for over sixty years. As I get older it gets worse. I cannot describe what I suffer so often. I thought if it could be opened it may be a very great benefit to others who suffered like me with their heads if the cause of all my head afflictions can be found out, which you warmly approved of. I can assure you, dear Sir, it will be a very great relief to myself and relations to know and to be sure that my most urgent and last wish will be fulfilled in having my head opened after death."

My patient having died on April 14th, I carried out a post-mortem examination on April 16th and found the following conditions most worthy of note: (1) The hair on the scalp was very thin and scanty. (2) There was marked atheroma of the mitral, tricuspid, and aortic valves; also of the coronary arteries of the aorta. (3) The under surfaces of the ribs were much thickened, even to the extent of half an inch in some places, and pressing downwards on the brain. The last condition was also, in my opinion, of congenital syphilitic origin and no doubt the cause of the headaches.

#### CONSTRICTION OF THE PENIS IN AN INFANT.

DR. T. WILSON AIRD (Margate) writes: The case of a feather in the parotid duct reported by Sir Dundas-Grant in the JOURNAL of March 10th, p. 416, reminds me of an unusual case which came under my care while acting as M.O. on an Atlantic liner years ago. One day I was asked to see the six-weeks old infant son of a German couple in the steerage. The mother informed me that for several days and nights the child had kept up an almost continuous murmuring cry whenever it was awake as if it was in constant pain, and that she could find no cause for this. On the child being undressed I observed that it was in a very dirty, uncared-for condition, and that the penis was deeply constricted in the middle as if a ligature had been tied round it, with the result that the distal half was swollen and inflamed to twice its normal diameter, while the proximal half appeared to be normal. With some difficulty I was able to partly separate the sides of the constriction and discovered the extremity of a hair pointing from left to right. On seizing this with dressing forceps and carefully unwinding I found it to be a human hair about 12 inches in length—presumably from the mother's head. The parents seemed as much surprised as I was. On further examination I found that the skin of the penis in its entire circumference had been completely severed down to the subcutaneous tissue, but fortunately the deeper structures had escaped. I was afraid lest the urethra had been damaged but events proved that this was not so. The child made a rapid and satisfactory recovery. I imagine that the hair had become attached to the infant's nightdress, then to the penis, and the natural imbrication of the hair set up and carried on the "encircling movement."

#### CORRECTION.

In the Contents page of the JOURNAL of May 5th the letters "F.R.S.Ed." were, through inadvertence, printed after the name of Dr. J. Argyll Campbell in place of D.Sc.Ed.

#### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 30, 31, 34, and 35 of our advertisement columns; and advertisements as to partnerships, assistantships, and locum tenencies at pages 32 and 33.

A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 191.

#### SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	...	...	0 9 0
Each additional line	...	...	0 1 6
Whole single column (three columns to page)	...	...	7 10 0
Half single column	...	...	3 15 0
Half page	...	...	10 0 0
Whole page	...	...	20 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, not later than the first post on Tuesday morning, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restants* letters addressed either in initials or numbers.

# A British Medical Association Lecture ON SOME CONSIDERATIONS ON DISORDERS OF GROWTH.\*

BY  
HUGH THURSFIELD, M.D., F.R.C.P.,  
PHYSICIAN, HOSPITAL FOR CHILDREN, AND ASSISTANT PHYSICIAN,  
ST. BARTHOLOMEW'S HOSPITAL, LONDON.

THERE is an old philosophical doctrine of the meaning of the universe expressed in the words *πάντα ῥεῖ*—everything is in a state of flux; nothing is stable. That is true of life in general and of human life in particular. Growth and development, degeneration and decay, are inevitable laws of Nature as we say—that is, these processes represent in our experience the recurring phenomena of life without a known exception. In our own department of the study of the phenomena of human life, in medicine, when we deal with the adult our principal business is the appreciation of the processes which lead to degeneration and decay, and we endeavour to influence conditions in such a fashion as to retard the operation of the inevitable law. But in the study of the infant and the child our attention is to a large degree concentrated on the opposite principle, the law which governs growth and development.

Till the middle of the nineteenth century our knowledge remained much as it had been in all the previous centuries of man's existence, but with the promulgation of the doctrine of evolution and natural selection an immense stimulus was given to the study of the development of the human being. New fields of investigation were opened and the modern science of physiology began to provide the ancient art of healing with new ideas. The results of the study of the thyroid gland introduced us to the functions of the glands of internal secretion, and speculations on the nature of inherited qualities and their transmission stimulated research into the origins of growth and development.

When we ask why the infant grows and develops, the answer which our present knowledge must give is that there are two principal factors: one the inherent stimulus which is common to all young life, which we recognize as a law of Nature; this we can analyse to a certain degree, and perhaps we may succeed in time in modifying it consciously in human life as we have succeeded in the vegetable and animal kingdoms. Eugenics is the branch of science which seeks this end. The other factor, over which we gain more control as time passes and knowledge increases, may be called the external factor, the law that growth cannot occur without a supply of the material which is to be built into the growing tissues, and even so can occur normally only if the material supplied is properly distributed and regulated by the various structures which we have learnt to regard as governing growth. These governing structures are the glands of internal secretion, and our knowledge of them, though it increases, is still pitifully small.

We can therefore recognize two spheres in which we can attempt to control growth—the ante-natal period and the period of growth after birth; and two factors which between them determine the nature and the course of growth—the glands of internal secretion, and the material supplied to them. It is obviously in the period after birth and in the nature of the material supplied that our best opportunity lies of influencing the development of the infant; but the ante-natal period is of increasing importance, and in one direction at least we have gained a measure of control over the ductless glands. The field thus sketched out is clearly far too wide for a comprehensive review, and I propose to select a few points in it for consideration.

## THE ANTE-NATAL PERIOD.

Congenital defects have always attracted much attention, but our knowledge of their causation is singularly small. Many of these defects are local and apparently the result of some aberrant impulse in the inherent principle of

growth. A good example is the congenital abnormality of the heart, or the congenital absence of some bone such as the radius. Some such events we classify under "atavism" or "reversion to type"—phrases which may help us to grasp the exceeding complexity of the human body as it exists at the present time, but throw no light on the stimulus which provokes the reversion. Such events we neither understand nor can attempt to control. On the other hand, we know that tuberculosis or alcoholism in the parents leads to a high percentage of mental deficiency in the offspring; and that a disease such as syphilis can be transmitted to the unborn child. Yet when we have counted all the recognized factors which influence the development of the foetus we are left with the great bulk of congenital abnormality wholly unexplained. We do not in the least understand why one of a pair of twins should be a Mongolian idiot, and the other a normal child; or why one child in a long family should be born with achondroplasia. You will be able to recall dozens of other examples in which as yet our knowledge is absolutely nothing. But we know enough of the facts of inheritance to be able to predict the probability of haemophilia in a given family; and we have mastered therapeutics sufficiently to secure that the child of a mother who was herself born a cretin should be a normal individual. Again, recent experimental work, to which I shall recur, seems to point to the fact that the absence or deficiency of certain elements of food in the diet of the pregnant or nursing mother has a marked influence on the growth and development of the offspring, and especially upon its skeleton.

But in the ante-natal period there remains a vast mass of unknown, unguessed-at factors which can only very slowly be revealed by the advance of eugenic study and the knowledge derived from researches on inheritance in animals and plants. Meanwhile, we in this generation must be content to do the recording and the classification so that the date of the revelation of the underlying principles may be hastened.

## THE PERIOD AFTER BIRTH.

Physiology deals with the function of the living organism, and its most obvious field of research is that which includes the supply of material to the increasing tissues; and though we know that growth may be stimulated by other factors of environment, such as air, light, and exercise, yet the quantity and quality of the food clearly holds the first place. Physiology early established the normal curves of infant growth and engaged in the task of analysing the quantities and qualities of the known chemical elements which go to the building up of the tissues.

## Vitamins.

Towards the end of the nineteenth century it had become clear that besides the proteins, fats, carbohydrates, and mineral salts which compose the essential chemical elements of food there must be other, hitherto unrecognized, substances essential to life. This was, of course, not a new idea—it had long been familiar to clinicians brought into contact with cases of scurvy; but the hypothesis was not accepted by all clinicians and was far from proof. Physiology sought the proof by the method of exclusion from the diet of everything except the recognized chemical elements. There was an interval before they were able to reach the desired standard of purity, but in the first decade of this century Hopkins at Cambridge was able to demonstrate conclusively that a diet of standard purity, though complete in quantity and quality as recognized by chemical analysis, was insufficient to maintain growth, and if continued led to death, usually from intercurrent infection. I need not detain you with the subsequent history. I will merely remind you that it is now established that over and beyond the recognized chemical elements of food there are three accessory food factors, or vitamins—fat-soluble A, water-soluble B, and the antiscorbutic factor C. Whether there are others than these is undecided. McCollum and his fellow workers at one time considered that fat-soluble A really contained two separate elements—one necessary to growth, the other necessary for the normal production of bone. More recently they have claimed the existence of a fourth vitamin, D, which is antirachitic, but at present the

\* Delivered before the Guildford Division of the British Medical Association on April 12th, 1923.

claim is not substantiated. It is possible that other vitamins exist, but with our present knowledge it is not very probable.

The discovery of these accessory food factors is of the first importance in our study of the disorders of growth. It is clear that no normal growth can occur in their absence, but we do not yet know clearly what are the effects of a mere deficiency in quantity. Nor shall we know this with accuracy until the efforts of the physiologists have succeeded in isolating the vitamins and determining their actual composition.

**Vitamin C.**—However, with vitamin C, the antiscorbutic factor, some progress in this direction has been made, and it is possible to estimate the quantity per kilo of body weight of orange juice or cabbage juice necessary to protect a guinea-pig against scurvy. In the infant it has long been known to clinicians that the effects of a scurvy-producing diet require some time to show themselves and that there are degrees of severity in their manifestations. With our knowledge of vitamin C some of this variability is explained. The milder cases and those which develop only after a long course of the scurvy-producing diet are presumably those in which antiscorbutic is not wholly absent but is present in insufficient quantity. And in those cases which are severe or develop after an extremely short interval of the scurvy diet the factor is presumably absent altogether. But clinical observation, stimulated by such considerations, has gone further, and Hess and others have shown that there is what we may call a latent or subacute scurvy which has not hitherto been recognized. There is a group of infants of from 3 to 6 months of age in which growth is defective, irritability pronounced, and there is obvious pain on handling. If such an infant is supplied with orange juice in good quantity these symptoms almost at once disappear and normal growth is resumed. Such infants have usually been fed either on food which is notoriously defective in antiscorbutic quality or breast-fed by mothers whose own diet has been similarly defective. I have in the past year seen two such cases, and the result of the addition of antiscorbutic to their food is striking. I think that besides the obvious haemorrhagic disorder of the older infants we must recognize the existence of a milder and less obvious scurvy which may attack the infant in the early months of life. We must further recognize that the nursing mother, though in normal circumstances amply supplied with vitamin C and able to transmit it to her infant, may be so situated that her own supply fails, and that with the failure the infant is exposed to scurvy. The remedy is to secure for every nursing mother an ample supply of the vitamin-containing foods, such as fresh fruit and fresh vegetables. On the whole the dangers of an insufficient supply of vitamin C are well understood; the chief addition to our knowledge is the appreciation of these minor and earlier manifestations in infants, whether fed artificially or by the breast.

**Vitamin B.**—On the whole, again, vitamin B, the water-soluble factor, seems to be very seldom, so far as our present knowledge goes, a factor in delay of growth. It is present so abundantly in so great a variety of foods, and it is so little affected by cooking processes, that a deficiency in this respect is hardly to be expected. I had hoped that a deficiency in this respect might be the explanation of our failure to deal successfully with some of the cases of infantile atrophy, but all clinicians are united in agreeing that the supply of this factor has no influence on the disorder. Nor have the results of administering yeast to older children suffering from chronic wasting disease been any more satisfactory. The claims of the manufacturers of patent foods may in this respect be entirely disregarded.

**Vitamin A.**—It is round the fat-soluble vitamin A that the greatest controversy rages and the most doubt exists. It is clear from the experimental work that without vitamin A growth fails; and it is also clear that if vitamin A is absent or deficient normal calcification of bone cannot take place. But it is also becoming clear that a failure or a deficiency in vitamin A is not the sole cause of rickets. In the controversy which has taken place the contention on the one side has been that rickets is essentially a deficiency disorder, and on the other that it is in the main caused by external conditions, especially by the absence of sufficient light and exercise. There are two facts which appear to

me to stand out from the mass of experimental work on this subject: one that it is difficult to produce rickets in an animal who is provided with a proper amount of vitamin A, of calcium, and phosphorus; the other that rickets is apt to be seen in animals whose diet is ample in these respects if the other conditions of their life are unfavourable. From some other experiments it would seem possible that these two apparently irreconcilable facts are in reality corollaries of each other. It would appear, for instance, that if the experimental animal is exposed to light—either sunlight or the light of the mercury vapour lamp—a much smaller amount of vitamin A is sufficient to inhibit the rickety changes in bone than is required by the animal who is brought up in the comparative darkness of the laboratory. Whatever the ultimate outcome of the investigations into the relationship between vitamin A and rickets, it is clear that the clinician must, as he has been doing for many years past, recognize that for his rickety patient an ample supply of animal fats is necessary. Fortunately all the researchers are agreed that cod-liver oil is a substance especially rich in fat-soluble A, so that by the simple addition of this drug to the food of an artificially fed infant the worst manifestations can be avoided.

I emphasized just now the importance to the pregnant or nursing mother of a supply of antiscorbutic factors. It would appear from some recent experimental work that the pregnant mother has also especial need of an ample supply of fat-soluble A. In Korenchevsky's experiments the young rats of two separate litters were weighed on the thirty-sixth day of their lives—both litters had been fed by their mothers and both mother rats had received during lactation exactly the same food. The one mother had, however, during her pregnancy received cod-liver oil in addition to the basal diet which both had; the young of this mother weighed on the average three times more than those of the other litter. Other similar experiments go to prove that a rat mother who is fed during her pregnancy on a diet defective in vitamin A will produce young with defective bone formation, due to a deficiency of calcium in the periosteum, and will herself tend to show a marked thinning of the bones.

#### *Osteogenesis Imperfecta.*

It is impossible with these experiments in our minds not to think of that obscure disorder of human growth which is best termed osteogenesis imperfecta. You will remember that there are infants born with so great a tendency to fracture of the bones that life is impossible; that others manage to retain a hold on life but with an extraordinary tendency to fractures and to marked curvature of the long bones; that others, again, with comparatively few fractures yet have bones so thin and slender that violence which would do no damage to a normal individual causes fractures. These various conditions have unfortunately been christened with a great variety of names, so that it is often difficult in reading of them to determine how far they are distinct disorders. My own impression is that there is but one disorder—osteogenesis imperfecta—and that fragilitas ossium, osteopsathyrosis, and infantile osteomalacia are merely varieties of severity. If this is correct I think it possible that Korenchevsky's experiments may indicate the cause of this disorder of growth: a lack of vitamin A during the pregnancy, and possibly a defective supply of calcium and phosphorus. From some other experiments it seems to be possible that the lack of vitamin A is the actual cause of the lack of calcium absorption. At any rate it is obviously the duty of the physician to ensure a good supply of vitamin A to the pregnant mother—an easy task, even when for any reason animal fats are difficult to procure or to digest, for cod-liver oil in quite small quantities contains vitamin A in abundance.

#### GLANDS OF INTERNAL SECRETION.

I have but touched the fringes of the subject in talking of vitamins, but I hope that I have been able to emphasize the great importance of the discovery, and the new field of hypothesis which it has opened. I must pass on to another portion of the subject—the relationship of the glands of internal secretion to growth and development. We are leaving to a large extent the sphere of experimental medicine and entering that of clinical observation, and too often

straying into that of mere surmise. So much has been written and is still being written on the ductless glands that it comes as something of a shock to realize how little we really know, and how much of what we sometimes consider knowledge is in reality nothing more than ingenious speculation. We know something of the influence of the thyroid on growth; less of the pituitary; and still less of the adrenal glands. We know that the interstitial tissue of the sexual glands, the testes and the ovaries, is of great importance for normal development. We believe that the parathyroid and the thymus have an intimate relationship with certain disorders. And we are just now apparently on the edge of conquest of a new sphere of control, in the isolation of the active principle of the internal secretion of the pancreas. I do not wish to enlarge on these topics. I want to turn your attention in a slightly different direction.

We have seen, in considering the subject of vitamins, that if you supply sufficient quantity and quality of food the young animal will grow in a normal fashion. But he will only do so if the glands which control growth are working naturally and in harmony with each other. If there is, for instance, a defect of the thyroid secretion growth will be abnormal; the creature will not cease to grow, but the increasing tissues will be distributed in the body in an abnormal way—the skeleton will develop abnormally; the fatty tissue will be excessive and curiously localized; and the mental powers will be defective. It is as if you had presented an architect with the richest material in proper proportion and asked him to build a shrine, and though he has used the material he has built a deformed and unsightly hovel. So it is also with a defect of the pituitary secretion, and with the victims of a defect of the interstitial tissue of the sexual glands. In the one case the failure of the pituitary architect may produce a "Fat Boy of *Pickwick*"; in the other the failure of the interstitial architect may produce the deformity of the body which we call the "eunuchoid" type. In the case of the cretin we have to a certain extent mastered the secret and can by addition of thyroid extract procure a more or less normal growth; in the hypo-pituitary abnormality we are only tentatively feeling our way; in the "eunuchoid" type there is, so far as I know, as yet no real success.

I want to digress for a moment to speak of the hypopituitary type. There is a group of children who exhibit a tendency to become very fat and at the same time to develop the fat especially in the hips, thighs, and abdomen; in addition their genital organs retain the infantile type, and towards puberty they exhibit none of the secondary sexual characteristics. Fröhlich was, I believe, the first to point out that this abnormality was sometimes associated with a tumour of the anterior portion of the pituitary gland, and it is often known as "Fröhlich's syndrome." What is perhaps not so well appreciated is that such a syndrome is often only a temporary phenomenon, and that after a time normal growth is resumed. The presumption is that there is a functional disorder which for a time diminishes the available amount of the necessary internal secretion. I have had some success in treating such children with extracts of the whole pituitary gland. One boy in particular was brought because he could not keep awake either in school or even at his meals. In this, as in his general appearance, he recalled Dickens's description of the Fat Boy. He had no sign of a pituitary tumour, but when placed on extract of the whole gland he became almost normal. He was discharged, but after an interval his father appeared asking for more of the tablets as the only means of keeping him awake. More often, however, therapeutic efforts fail: we do not know enough of the conditions.

In such forms of abnormal growth there is an inherent defect in the functions of the glands of internal secretion, but there are other conditions in which we have reason to suppose that the alteration of the secretion is brought about by factors over which we may learn to gain a degree of control. For example, it is a notorious fact that after some infectious diseases growth may take place with unusual rapidity. After an attack of typhoid fever, for instance, the adolescent may suddenly increase several inches in height; while the adult may become alarmingly stout. On the other hand, there are two diseases of childhood which in my own experience exert the opposite effect. Both

diphtheria and tuberculous peritonitis may for a time completely stop growth in height and weight, and I think it is usually a matter of a couple of years before growth is resumed, so that either of these diseases may leave a permanent mark. In these instances I think we are obliged to look for an explanation to some functional disorder of the glands of internal secretion, and I am at present trying the effect of increasing doses of thyroid on one such case, with the result that he has put on a pound a month since he began the drug, whereas for the previous year the total increase had been less than two pounds.

Somewhat in the same category I should feel inclined to place the celebrated case recorded by Byrom Bramwell, in which the addition of pancreatic extract transformed in a year or two a real dwarf into a small but fairly normal individual.

Lastly there is a group which is much less hopeful but which is, from our present standpoint, of great interest—the group of "renal" dwarfs. They were recognized and described by Morley Fletcher in adolescents some years ago and have been written about a good deal since. But quite lately my colleague Donald Paterson has shown that there is a similar group with characteristic lesions in the skeleton, recognizable by x-ray examination, occurring in the infant, and I have recently had in my charge a child of 7 years who seems to me to represent another type of the same abnormality. Whether their dwarfism is due to an internal secretion of the kidney, or can more justly be referred to a poisoning of the sources of growth, is a matter which must be left for later research.

There is, of course, much more that could be said on such a subject, but I hope that I have succeeded in sketching the intimate relationships which appear to exist between the materials and the architects: that the architects cannot work without the proper materials, and that improper material may impair the powers of the architect for a short time or even permanently; and that with architects of inferior powers or out of harmony with each other good material may be built into monstrosities.

## The Middlemore Lecture, 1922,

ON

## REFRACTION.

DELIVERED AT THE BIRMINGHAM EYE HOSPITAL

BY

T. HARRISON BUTLER, M.D., B.Ch.Oxon.,  
SURGEON, BIRMINGHAM EYE HOSPITAL.

(Abridged.)

DR. RICHARD MIDDLEMORE founded this lecture in order that it might year by year afford the medical men of the Midlands an opportunity to hear the latest views upon an ophthalmic subject of general interest. I therefore do not apologize for selecting refraction as my subject.

The field for refraction is unlimited, and it is quite impossible for ophthalmic surgeons to handle the whole. At the present time the majority of the cases are dealt with either in hospitals or by men who do not possess a medical training. There is no reason why much of this work should not be undertaken by the general practitioner to the advantage of himself and his patient. If he decide to take up refraction he must adopt modern methods and learn retinoscopy.

Refraction cannot be learnt from books, and retinoscopy demands considerable practice. Probably the average man will require three months' constant work in an eye clinic before he attains the necessary accuracy. This period will not be wasted, for both from the standpoint of diagnosis and treatment a working knowledge of ophthalmology, not excluding refraction, is indispensable to the up-to-date physician.

### THE OBJECTS OF REFRACTION.

The object of refraction is to make the patient comfortable, not the solution of a problem in optics. Glasses are prescribed to enable an individual to see clearly, and to relieve symptoms caused by errors of refraction and of muscle balance. It does not follow that spectacles which

accurately correct an error will be comfortable; on the contrary, a man may prefer indifferent vision to wearing glasses which he dislikes. In cases of this kind we must temper our desire for optical perfection with common sense. If our patient is quite satisfied with his moderate acuity, and does not suffer from the symptoms of an error of refraction, then he may, if an adult, choose for himself when he will wear his spectacles. We prescribe the glasses to be worn when he wishes for clear vision, and we attain our object, which is to make him physically and psychically comfortable. In the case of a child the conditions are different, and we allow no such latitude. An infant with poor acuity will grow up with unsocial habits and will not develop the habit of observation. He must wear his spectacles constantly.

#### SYMPTOMS CAUSED BY ERRORS OF REFRACTION.

The chief and obvious symptom is failure to attain to the normal standard of acuity. Using the ordinary Snellen's test types with the standard illumination this must be taken not as 6/6 but as 6/4.5. In actual practice for all ordinary work 6/12 is sufficient, so if the acuity is 6/12 or better, glasses are not called for in the absence of symptoms due to an error of refraction.

*Headache* is the next commonest symptom. In every case of headache the eyes should be examined both for refraction error and for disturbance of the normal muscle balance. It does not follow that a refractive error is the cause of the headache nor that its correction will cure the headache. If the spectacles have no favourable influence upon the pain, and if the acuity be good without them, then there is no necessity to wear them. I wish to emphasize the fact that many men and most women object to wearing glasses, and if they are of no use there is no valid reason for employing them. Headache may be due to migraine, to nasal sinusitis, and to many other causes, which may coincide with an error of refraction which is not responsible for the pain.

The degree of error is not proportional to the trouble it causes. In one individual a considerable amount of astigmatism may cause no symptoms, whereas another may suffer agonies from a minimal defect. There are some who possess an abnormal visual acuity—they may be able to read all the letters in the 6/3 line; such are very prone to be inconvenienced by a trivial refractive error. Others, with a highly excitable nervous system, may be relieved from life-long misery by a 0.25 cylinder. We must not, however, allow exceptional cases of this kind to pervert our judgement; in young persons slight astigmatism with the so-called rule, and in the aged against it, is so common that it may be taken as normal, and in most cases causes no symptoms.

*Pain in and about the eyes* is, after headache, the most frequent complaint. This may be, and in fact often is, due to an abnormality in refraction or muscle balance, but it can be a pure neuralgia. Countless women complain of ocular neuralgia, often associated with pain elsewhere; intercostal neuralgia, rachialgia, coccygodynia, sciatica, and dysmenorrhoea—such are not in the main relieved by glasses; the pain must be treated along ordinary medical lines generally with scant success.

*Vertigo*, in my own experience, is one of the rare symptoms. It may be caused by muscle imbalance, especially by a high degree of hyperphoria, but the large majority of those who have come to me complaining of giddiness have, if young, been suffering from an aural trouble, and if aged, from circulatory disturbances in the brain.

The essential symptoms of an error of refraction or of muscle balance are: poor acuity, headache, asthenopia, and very occasionally vertigo; but a host of others have been associated with these defects; in fact our American colleagues have given a long list of nervous and even of more general affections which they have treated by correcting errors of refraction. In this connexion we must steer a middle course and not allow enthusiasm to blind common sense. It is doubtless true that an individual of highly neuropathic habit may suffer in various ways from the constant strain of an uncorrected error of refraction, and it is a fact that such may derive benefit from wearing spectacles, at any rate for a time—in some cases from relief of strain, in others from pure suggestion; but, on the other hand, the extravagant lengths reached by some regarding the effects of eyestrain have given rise to much confusion of thought and to not a little frank charlatanism. Every

specialty tends to run to extremes and may even approach quackery. The term "eyestrain" has been so much abused in the commercial sense that I prefer to avoid it. There is no doubt that eyestrain exists, but it is not nearly so common as some would have us believe, nor are its effects in the main so baleful as is commonly supposed.

#### METHODS OF DETERMINING ERRORS OF REFRACTION.

The only satisfactory objective method of determining an error of refraction is by retinoscopy; it is the Alpha and Omega of refraction, and a man who is incapable of accurate retinoscopy will never achieve much success in refraction. Accuracy can be attained only by long and constant practice, but much may be done by attention to detail.

The apparatus necessary is of the simplest character: we require an adequate box of accurate trial lenses, a good trial frame, test types correctly illuminated, and a flat retinoscopy mirror. We must work in a room which is at least 20 feet across the diagonal, and we require a small but bright source of light.

Probably few to-day use the concave mirror; it has nothing to recommend it, and in my hands has never yielded accurate results. In many mirrors the hole is too large; I find that 3 mm. gives the best effect, and of all patterns I prefer that designed by Priestley Smith.

The source of illumination should be about the size of a shilling, and having cut down the size we must compensate by using a brilliant light. I think that the best illuminant is paraffin—a lamp with a round wick half an inch in diameter—but electric light is more convenient. I employ a 40 candle-power frosted globe in a Thorington's chimney with an iris diaphragm. This limits the general illumination of the room, and a shaded reading lamp will be convenient to light the box of lenses and the notes. The room should not be completely dark; objects at the end should be visible, otherwise, working without a cycloplegic, it will be impossible to secure full relaxation of accommodation. The old-fashioned dark room is an anachronism; it is better to work in a room with curtains sufficiently thick to obscure but not entirely exclude the light.

The retinoscopist must learn to use both eyes with equal facility, otherwise when a cycloplegic is not employed he cannot refract near the macula, because his head will prevent the patient from fixing an object immediately behind him, and the retinoscopy will be inaccurate. It is essential that the surgeon have good personal acuity, that he may appreciate the tenuous central shadows which alone determine the point of reversal.

In difficult cases it is wise to use cylinders as well as spheres. When the astigmatism has been approximately determined place the appropriate cylinder in the trial frame and alter it till a sphere corrects both meridians simultaneously. This method is very sensitive and is especially valuable when working without a cycloplegic.

Errors in retinoscopy depend almost entirely upon failure to work near the macula. In many eyes the posterior pole is not truly spherical and slight eccentricity in the retinoscopy may introduce an error of a dioptre or more. Generally speaking, retinoscopy should be accurate to within a quarter of a dioptre, but there are cases with scissor shadows and other manifestations of irregular astigmatism in which the limit value is far higher. Corneal nebulae render retinoscopy difficult and often impossible.

If a cycloplegic be used incomplete paralysis of accommodation is a fertile source of error, in fact it may be far greater than we are likely to get without the use of a drug. This has been forced upon my notice in school clinic work, and I have concluded that to obtain certain paralysis of and I have concluded that to obtain certain paralysis of and I have concluded that to obtain certain paralysis of the ciliary muscle in children atropine must be used, and it must be instilled over a period of twenty-four hours. The majority are ready for the test after three instillations spread over two hours, but there are frequent exceptions.

In all cases, except infants who cannot read, the final adjustment will be made with the trial lenses and test types. Intelligent children over 5 years old will give valuable information during the subjective test, in fact they are often more helpful and sensible than some adults. There is a tendency to underrate the intelligence of the child.

When each eye has been examined separately it will often happen that together they will take a stronger convex lens, a fact that has been emphasized by Priestley Smith.

### The Use of Cycloplegics.

There is still a wide difference of opinion to what extent we should use cycloplegics in refraction. My own views upon the subject will be found in a paper which I read to the Congress of the Ophthalmological Society in 1922.<sup>1</sup> My practice is to use atropine for young children, but to refract the majority of my patients without cycloplegia.

Cycloplegics are necessary in infants who have not sufficient concentration to fix a distant object, and in cases of spasm of accommodation. Hirschberg tells us that this is one of the rarest of ocular abnormalities, and most ophthalmologists will agree with him. I can only recollect half a dozen cases, and in each the spasm was obvious and detection easy; I am sure that spasm is a boggy. We meet with the ready and powerful accommodation of the young and the irritable action of the ciliary muscle in neurotic persons. Such may not easily accept the full correction of their hypermetropia, but I find that a properly conducted retinoscopy will rarely fail to show the full amount. If the patient will not accept the total correction of hypermetropia as shown by the shadow test, then it is wise to check the result with a cycloplegic. Generally the final result is the same.

Although it is permissible for the experienced to work largely without cycloplegics, the beginner will use them frequently; with increasing practice he will gain confidence and that instinct for spotting the "wrong 'un" which comes from constant association with patients, and he will use drugs less and less. I find that homatropine is not a reliable cycloplegic, and that it frequently gives less hypermetropia than one gets without it. I have found this anomaly after instilling a 2 per cent. solution three times during an hour or more.

In any case, assuming that an occasional error is made by working without a cycloplegic and that no errors accompany its use—a very large assumption—even then I prefer this infrequent lack of accuracy to submitting a large number of my patients to the discomforts of cycloplegia.

### VARIETIES OF ERRORS OF REFRACTION.

#### Myopia.

Myopia is the most interesting and important error of refraction—interesting because of the uncertainty of its genesis, and important because it so frequently ends in grave loss of sight and even blindness.

There are two types of short-sight; one we may call overgrowth myopia, the other progressive myopia. The first is a developmental anomaly, the second a disease.

Emmetropia is the result of a correct balance between the strength of the dioptric system of the eye and its distance from the retina. The young eye is hypermetropic and attains its final refraction when its growth is complete. In most cases the eye finishes with a more or less correct balance between axial length and lens strength, but there are units above and below the base line. On the one side we have cases in which the eye is short in proportion to lens power (the hypermetropes), and on the other those eyes which are too long in proportion to dioptric strength (the myopes). These myopes are not diseased, and the error, which rarely exceeds 3 dioptres, does not as a rule alter.

Progressive myopia is entirely different; here we have an eye in which the posterior segment gradually elongates. In time, if the stretching passes a definite limit, the sclera expands faster than the inner tunics of the eye, and there is developed first a myopic crescent, and eventually a posterior staphyloma. At the same time low-grade inflammatory changes take place in the choroid, and the retina begins to suffer, more especially at the macula. Haemorrhages may appear at the fovea, and large areas of the retina and choroid disappear, leaving extensive white plaques of bare sclera at the posterior pole.

These destructive changes are accompanied by serious loss of acuity. In some cases the retina refuses to stretch any further and becomes detached. I think that this tragedy is more frequent in cases which do not show the extensive destruction of the choroid that I have mentioned, but it may take place in any case of progressive myopia even when of comparatively low degree.

### Causes of Myopia.

For many years there has been much discussion about the cause of myopia. A generation has passed since Cohn and his supporters coined the objectionable term "school myopia," and put forward the theory that advancing short-sight was due to the effect of close work. The upholders of this view showed that the degree and incidence of myopia increased in proportion to the age of the scholars, and that myopia was more common in those who used their eyes for near work than in others who led an open-air life. The first statement is true, and it is equally valid for the length of nose or leg in the same children. The second is but partially true. Statistics of thousands of cases of myopia are available, drawn from German, British, and other sources. They bring out the curious fact that examples of progressive myopia of the worst type with fundus degeneration are more common in agricultural than in urban districts. Moderate myopia is commonest in towns, advanced in the country. The most recent and conclusive figures were published by Ernest Thomson. He found that severe myopia was commonest in mining districts, less so in agricultural areas, and still less in towns. My own feeling is that in the Midlands myopia is commonest among miners, but I have no exact figures to go upon.

The reason is clear: in a mining village it is almost a social crime to marry out of the community. In most villages there are few surnames and the whole population is related. In towns the conditions are different. The result is that the miner is the product of close in-breeding, an agriculturist of in-breeding, the urban dweller of cross-breeding. These facts point to the real cause of myopia—heredity. Myopia is also a racial disease. It is said that it is commonest in the Roman Campagna, because for centuries this area has been the recruiting ground for the constant wars of the past; the myope was rejected for military service and lived to perpetuate his kind. Short-sight is notoriously prevalent in Germany—decimated by the thirty years' war—and among the Jews. Myopia is rare in Britain, a country that has been spared the annihilating wars of the Continent.

The objections to the theory that myopia is due to close work *per se* are to my mind conclusive. The suggestion is that during the act of accommodation and convergence the intraocular pressure rises and gradually distends the organ. It has not been proved that such a rise of tension actually takes place, and even if such were the case the conditions found in the myopic eye are not those which are present in an eye which has been subjected to real well defined high tension. In glaucoma the hypertony is associated with cupping of the optic disc, whereas in myopia the stretching is more evident further forward. It is by no means uncommon to find myopia in infants, who have not used the eyes for near work, and cases are common with high myopia in one eye alone. These facts are all against the theory that close work causes myopia. We must seek another cause, and we find it in heredity.

I have dealt with the genesis of myopia at some length because there is a danger that false theory may be followed by worse practice. There is to-day a tendency for educational authorities to deprive myopes of the benefit of a liberal education. It is suggested that a child with more than three dioptres of myopia shall not be allowed to hold a scholarship, and young children with short-sight are herded into special myope schools. Special schools are necessary for children whose sight is so bad that they cannot be educated in an ordinary establishment, but if the child has sufficient sight to benefit by the general school he should not be condemned to an inferior system unless it has been proved that work under these conditions will be detrimental to his sight. It seems to me that it is not even probable that this is the case. It is true that confinement in a badly ventilated, indifferently lighted school will affect the general body tone, and that the resistance of the sclera will be lowered with the general deterioration of tissue nourishment. This consideration has great weight in the management of cases of myopia. Such must have as much fresh air as possible with sufficient exercise and

plenty of good food. In my private practice I allow myopes to continue their education, but I forbid music and novel reading. The child must read outside school work in the vacation, and if he take up music seriously he must not think of examination training. After an illness the myope needs a long rest, for it has been noted that an increase in myopia synchronizes with debilitating disease. The myope must be examined once a year and he must wear his full correction constantly.

It was once the custom to order special reading glasses for myopia. It was supposed from anatomical considerations that the ciliary muscle was weak and accommodative power defective. In the majority of cases, and especially in the young, this is bad practice. The myope has ample accommodative power, and he becomes presbyopic at the same age and to the same degree as the emmetrope. If, however, an adult myope has never worn a correction, he has not trained his accommodation, and for a time he will find it difficult to read with a full correction. If his myopia be under three dioptres the average man will wear his glasses for far sight only.

No rules can be laid down for the correction of very high myopia, nor for the strongest lens that can be worn with comfort. I furnish my patient with the lens which gives him the maximum acuity even if he cannot wear it constantly. The rule is to give our patients the best acuity possible with due regard to comfort.

#### *Hypermetropia.*

A high degree of hypermetropia will call for a constant correction, but it is unnecessary to order spectacles for moderate long-sight which is causing no symptoms. All depends upon the individual: some must wear their glasses always, others for near work only, while a third category can read and sew comfortably without optical aid. The young eye has an immense reserve of accommodative power and can utilize it without detriment as long as the general health is good.

#### *Astigmatism.*

The greatest care is necessary to obtain an accurate measure of the angle and degree of the astigmatism of an eye. Retinoscopy will give the approximate figure within about half a dioptre, especially if a cylinder is used for the final determination, but the ultimate choice depends upon the patient himself. Some of the astigmatic clocks are useful, but I depend upon a good set of test types with standard illumination, and I make the last adjustment with the aid of Jackson's crossed cylinders. A very few patients, and those mostly with an acuity of 6/3, are able to appreciate a difference of one-eighth dioptre, and they must be refracted within this limit, for they may be uncomfortable if the cylinder be not accurate to an eighth of a dioptre.

If the examiner is not a skilled retinoscopist he will have to fall back upon the astigmometer. This is a very expensive instrument, and, as it measures the corneal curvatures only, it cannot be accurate in the presence of any lental astigmatism.

A full correction should be ordered for astigmatism except when it is extreme; in such a case it is wise to undercorrect the astigmatism at first and proceed to the full correction when the patient has become accustomed to the first glasses. In any case we warn our patients with high astigmatism that they may at first suffer from some distortion when the error is corrected. Very high cylinders can be worn with comfort. I have a patient who gets excellent acuity with a 14 dioptre cylinder and complains of no discomfort.

#### *Presbyopia.*

The correction of presbyopia is not difficult if we use common sense; we must curb our desire for scientific accuracy, for few of our patients will appreciate the work of Donders. Generally speaking it is safest to undercorrect presbyopia. After 50 it is better not to add more than 2.5 dioptres to the distance correction. Even if the smallest print cannot be read and the work has to be held at a greater distance, the under-correction allows for work at a middle distance, and is more convenient for writing. In many cases we order three pairs of glasses—one for far,

the second for near, and the third for music. A low myope over 50 years of age will often be well suited with a pair of lenses one dioptre under the full correction. These will give him an acuity of about 6/12, which is ample for everyday requirements; they will afford full acuity for middle distance, and with them he can read large print.

#### SPECTACLES.

It is important that the lenses shall be correctly placed before the eyes, for all the work of a careful surgeon may be stultified by a careless and ignorant optician. For most purposes spectacles are better than pince-nez, but there are types of pince-nez which are perfectly satisfactory. The form which has a horizontal split bar and a coiled spring must be avoided, for it does not maintain a fixed distance between the optical centres and soon loses its rigidity.

Meniscus lenses and torics are best avoided for the following reasons: the optical advantages are largely theoretical, they are fragile and expensive, and they are disfiguring. No woman should wear torics. A pair of flat lenses with a delicate central mount is almost invisible, and gives a glint of light in but few positions. The toric reflects light in every position and gives the wearer a glazed appearance, hiding the eyes. Except for special occupations there is little or no advantage in Crookes's glass, which is expensive and absorbs much useful light. The combination of toric lenses and Crookes's glass is a fruitful source of financial loss to the poorer classes of society. In general the public will choose its own fittings and we should avoid any interference with individual preference, merely indicating what we consider to be the best or essential.

#### CHANGES IN REFRACTION.

The refraction of an eye cannot be regarded as final and unchanging. During the growth of the eye, in adult life and in old age, alterations occur—some regular and progressive, others irregular, and a few oscillatory in nature. I have not time to enter fully into this interesting aspect of the subject here, but I will briefly summarize a paper which I read to the Oxford Ophthalmological Congress in July, 1922. It is to be found in the *Transactions of the Ophthalmological Society*, vol. xlii, p. 293. I came to the conclusions that:

(1) The growing eye, examined from time to time, may show considerable alteration as regards sphere and cylinder. The astigmatism may alter both in amount and direction.

(2) In most cases equilibrium is reached when growth ceases, and the refraction is stabilized till old age, when the eye tends to alter in the direction of more hypermetropia. This change is by no means constant, in fact it is probably as often absent as present.

(3) In other adults progressive changes take place, chiefly in the amount and angle of the astigmatism, and in the main they are such that they tend to replace astigmatism with the rule by that against the rule—that is to say, that in the young a convex cylinder is more frequently vertical than horizontal, whereas in the old the reverse is found. This alteration is effected in two ways: there may be a gradual swing of the angle from the vertical towards the horizontal, or the astigmatism with the rule may diminish, disappear, and reappear against the rule. Such being the case it is advisable to examine our patients about every five years.

In addition to these alterations, which probably depend upon variation in the shape of the cornea, and perhaps upon lens changes, there are others caused by disease. Thus diabetes not infrequently gives rise to myopia which is due to an increase in the refractive power of the lens. Occasionally the reverse change may be noted. Cataract, again, may have a similar action. When a man who all his life has had good sight becomes in later years short-sighted, diabetes should be suspected.

#### ERRORS OF MUSCLE BALANCE.

Heterophoria is theoretically a difficult subject, but, fortunately, for all practical purposes its detection, measurement, and correction can be carried out along simple lines.

If means are taken to abolish fusion the visual axes of the two eyes should remain approximately parallel. This state is called euphoria or orthophoria. If one axis rises or falls with reference to the other the condition is called hyperphoria or hypophoria. Diverging axes are named exophoria, and crossed axes esophoria. There is

in heterophoria a tendency for the visual axes to depart from parallelism, and the necessary co-ordination is effected by excessive use of the fusion faculty. When the muscles are fatigued this state of suppressed squint may become actual strabismus, and diplopia may be complained of.

It is obvious that heterophoria disturbs the co-ordination between accommodation and convergence, and that increased nervous energy is used up in each act of combined vision. In consequence fatigue will develop and cause asthenopia and headache. It is therefore essential that the error shall be corrected. I shall not here go into the details of the examination. We use the Maddox rod

and tangent scale for testing the muscle balance at infinity, and the Maddox wing test for measuring the error at reading distance.

Hyperphoria causes most trouble, but is not common. The most frequent defect is weakness of converging power, and this causes difficulty in reading and needlework. It is corrected by adding prisms base in to the near glasses, and such an addition is greatly appreciated by those who have convergence insufficiency.

## THE INFLUENCE OF INSULIN UPON ACIDOSIS AND LIPAEMIA IN DIABETES.

(A Preliminary Communication.)

BY

H. WHITRIDGE DAVIES, CHARLES G. LAMBIE,  
D. MURRAY LYON, JONATHAN MEAKINS,  
AND WILLIAM ROBSON.

(From the Department of Therapeutics, University of Edinburgh.)

THE effect of insulin in reducing the blood sugar of animals and of man has now been well established. Its similar action in an enhanced degree has also been found in cases of diabetes mellitus. In addition to reducing the high level of blood sugar in diabetes insulin has been shown to have the

percentage of the normal (Haldane<sup>2</sup>). The ketone bodies were estimated by the method of Van Slyke and Fitz,<sup>3</sup> while the respiratory quotient and hourly metabolism were determined by the Douglas bag method. The lipaemia was determined comparatively by centrifuging the specimens of blood and noting roughly the degree of lipaemia of the plasma. Four stages were recognized: ++ where there was a definite layer of creamy fat above the plasma, + where there was marked opacity of the plasma, + where there was moderate opacity, and ± for a slight cloudiness.

The following cases are examples of those which have so far been investigated. It was considered advisable to make observations upon cases with a moderate degree of diminished bicarbonate reserve in order to have a comparison between normal people and diabetics without any such reduction, and those cases showing evidence of impending coma.

FIG. 1.

Fig. 1 (Case I).—B.R. = Bicarbonate reserve percentage (normal 100 percent.). R.Q. = Respiratory quotient. Cal. = Calories per hour calculated from respiratory exchange. B.S. = Blood sugar percentage. B.K. = Blood ketone bodies in milligrams per cent. The respiratory quotient and the blood sugar percentage have been multiplied by one hundred in order to show them by means of the same scale of ordinates. Abscissae = time in minutes from commencement of observation. Patient fasting; weight 32.3 kilos. Insulin 10 units at point shown.

FIG. 2.

Fig. 2: Patient fasting; weight 32 kilos. Insulin 4 units at A. Glucose 16 grams at B.

Fig. 3 (Case II).—Letters and conventional signs as in Figs. 1 and 2. Patient fasting; weight 31.1 kilos. Insulin 10 units and glucose 20 grams at A. There was no lipaemia in this observation.

power of increasing the utilization of ingested carbohydrate. It is these facts which make the introduction of insulin of such importance in the treatment of moderately severe cases of diabetes.

In severe cases, however, other and more alarming disturbances are found. Lipaemia, increase of the ketone bodies in the blood, reduction of the bicarbonate reserve, together with hyperpnoea and mental disturbances, are all symptoms of great importance and frequently are forerunners of disastrous results. It seemed of importance, therefore, to ascertain how far insulin might remedy or prevent the occurrence of these conditions.

### Methods.

The blood sugar, bicarbonate reserve of the whole blood, and the percentage of total ketone bodies in the blood were estimated, and where possible the hourly metabolism and respiratory quotient were determined. The blood sugar was estimated by the method of Folin and Wu,<sup>1</sup> the bicarbonate reserve was estimated by determining the carbon dioxide combining power of the blood at 40 mm. of mercury pressure of carbon dioxide, the amount found being expressed as a

### CASE I.

F. H., a woman aged 24, was a case of severe diabetes that had been under observation from time to time for two years, giving a history of diabetic symptoms for three years. Her diabetic condition had progressed over numerous periods of exacerbation and remission, her carbohydrate tolerance diminishing from 67 grams a day to her present condition, in which 10 grams a day produce glycosuria. Observations were begun at 9 a.m. after sixteen hours' fasting, and were carried out under basal conditions as far as possible. The blood sugar before insulin was given was 320 mg. per cent., while the bicarbonate reserve was between 60 and 70 per cent. of normal (Fig. 1). Ten units of insulin were given and frequent examinations of the blood were made during the subsequent three hours. It will be noted that there was a steady decline of the blood sugar until it reached the level of 90 mg. per cent. Coincidentally there was an increase of the bicarbonate reserve from 59 per cent. to 91 per cent., and a decrease of the ketone bodies from 42 mg. per cent. to 8 mg. per cent. During this period the hourly metabolism varied but little, although the respiratory quotient showed a considerable change. The lipaemia rapidly disappeared. At the end of the observation the urine was free from sugar and ketone bodies.

On another day the patient was the subject of a second series of observations, which were carried out under similar basal conditions (Fig. 2). It was considered of importance to determine whether the administration of glucose with insulin influenced the response in any way. Therefore half a gram of glucose for each kilogram of body weight was administered shortly after insulin. Although the blood sugar was at approximately the same level as on the previous occasion, the bicarbonate reserve was not so much decreased. However, the results were similar to those already found. As on the previous occasion, lipaemia was present at the commencement and rapidly disappeared. The respiratory quotient was more constant, and showed a definite and gradual increase and decline after the administration of insulin and glucose. The blood sugar curve increased for a time, but at the end of one hundred minutes it had returned to its fasting level, and then declined still further. The decrease in the ketone bodies was most conspicuous, being reduced from 48 mg. to 6 mg. per cent. at the end of eighty minutes. As at the end of the previous observation, the urine was free from ketone bodies.

## CASE II.

E. A., a woman aged 20, was admitted to the Royal Infirmary a fortnight previous to the observation suffering from thirst, polyuria, and emaciation of about nine weeks' duration. Two days after admission her blood sugar was 222 mg. per cent., and the urinary sugar 4.7 per cent. (105 grams in twenty-four hours). She showed only a moderate degree of acetonuria. Four days later she became sugar-free, but the acetonuria remained, although there were no symptoms suggestive of a severe acidosis. This observation (Fig. 3) showed results somewhat similar to those of Case I (Fig. 2).

## CASE III.

J. I., a woman aged 30, was admitted to the Royal Infirmary having suffered from diabetes for eighteen months. The day after admission she developed mental symptoms, having hallucinations and delusions. A few hours later there was considerable hyperpnoea, and she became semi-conscious. The blood sugar at this time was 601 mg. per cent., and the bicarbonate reserve was only 40 per cent. of the normal. She was treated with insulin, glucose, and alkali (in the form of disodium phosphate). During the first twelve hours she received 40 units of insulin and 17 grams an hour of carbohydrate. The blood sugar steadily increased until at the end of twenty-four hours it amounted to 1,000 mg. per cent. (Fig. 4). A parallel increase of the bicarbonate reserve occurred; at the end of twenty-four hours it was 70 per cent. of normal, at the end of forty-eight hours 90 per cent., and at the end of seventy-two hours 4 per cent. above normal (104 per cent.). On the second day she received 80 units of insulin with 19 grams of carbohydrate an hour. On the third day 60 units of insulin with 15 grams of carbohydrate an hour. During this period the blood sugar fell from 1,000 mg. per cent. to 500 mg. per cent. On the fourth day she received 80 units of insulin with 1 gram of carbohydrate an hour. The blood sugar rapidly fell to 150 mg. per cent., and the urine was free from sugar. The insulin was reduced and the carbohydrate increased, with a rapid increase of the blood sugar but no appreciable diminution in the bicarbonate reserve.

Within twenty-four hours of the onset of the acute symptoms of acidosis and semi-coma the patient was quite conscious and all evidence of her acute crisis had passed away. During the succeeding days, however, her mental condition was far from normal, and she still had certain hallucinations and delusions, but these rapidly disappeared, and her condition continued along the usual course. It seems probable that this mental condition may have been due to organic changes in the central

nervous system, the result of the severe disturbance of cellular metabolism.

## CASE IV.

Mrs. P., aged 44, had evidently been suffering from diabetes for a few months only, and was admitted to the Royal Infirmary in a state of diabetic acidosis verging upon coma. She was quite incoherent in her remarks, and did not appreciate her surroundings. There was considerable hyperpnoea with tachycardia and great prostration. The blood sugar amounted to 390 mg. per cent., the ketone bodies in the blood to 62 mg. per cent., and the bicarbonate reserve was but 45 per cent. of normal (Fig. 5). The lipaemia was considerable. In view of the results obtained in the cases already outlined it appeared to us to be very important to determine whether insulin and glucose alone, without the administration of alkali, would have the same beneficial effect as was obtained in Case III. The alkaline reserve, ketone bodies, and blood sugar were estimated every four hours, and at these periods insulin and carbohydrate were given (Fig. 5). During the first twenty-four hours in hospital 120 units of insulin and 190 grams of carbohydrate were given. At first there was a slight rise in the blood sugar from 390 mg. per cent. to 440 mg. per cent. During the succeeding twenty hours there was a steady decline, until at the end of twenty-four hours it amounted to only 110 mg. per cent. The increase in the bicarbonate reserve followed almost a straight line from 45 per cent. to 89 per cent. of normal, the decrease of the ketone bodies following almost a parallel course. The lipaemia had disappeared at the end of ten hours.

The improvement noticed in the patient's condition during the first sixteen hours was most spectacular, and at the end of twenty-four hours she appeared practically normal. In spite of the large quantity of carbohydrate taken, the glycosuria during the first seven hours amounted to but 5 grams an hour, for the next twelve hours it averaged three-quarters of a gram an hour, and during the last five hours there was but a trace, the urine at the end of twenty-four hours being sugar-free.

In view of the results obtained in these cases it seems to be indicated that insulin and carbohydrates, when given together in sufficient amounts to patients with diabetic acidosis verging upon coma, have a most beneficial and indeed spectacular effect.\* The rapid disappearance of the lipaemia and ketone bodies of the blood, and the return to normal of the bicarbonate reserve, clearly indicate the means whereby this improvement is brought about. In Case III the great increase in the blood sugar did not appear to have any deleterious effect—in fact we have reason to suppose that an adequate supply of carbohydrate is most important in the treatment of such cases, and that in view of the known deficiency of glycogenic function this supply must mainly be available in the form of sugar in the blood and tissues. If it be true that the acidosis in diabetes is the result of the imperfect oxidation of fat through the inability of the cells to use carbohydrate, such results as we

have obtained are quite to be expected.

It is noteworthy that the reduction of the blood sugar was not always accompanied by such an increase of the respiratory quotient as might be expected if the sugar had been burnt. Determination of respiratory metabolism in emotional subjects may not give a proper indication of the

\* We wish especially to emphasize the importance of combining carbohydrate administration with the use of insulin in cases such as the above. We have evidence that the administration of insulin alone may increase the amount of acidosis present. This question is at present under investigation.

FIG. 4 (Case III).—Letters and conventional signs as in previous figures. Dotted line with crosses = insulin units per day. Total rectangles = carbohydrate ingestion grams per hour. Dark shaded rectangles = carbohydrate excretion grams per hour. Light rectangles = difference retained.

FIG. 5 (Case IV).—Letters and conventional signs as in previous figures. Dotted line with crosses = grams of carbohydrate taken. Dotted line with circles = insulin units administered. Rectangles = sugar excreted, grams per hour.

true respiratory quotient owing to irregularities of the breathing. Yet in such cases as the above there is another factor to be considered. The liberation of alkali in the blood consequent upon the removal of the ketone bodies would result in a compensatory retention of carbon dioxide. This might easily be sufficient in amount not only to mask any rise but even to produce a fall in the respiratory quotient. It will be noted in Fig. 1 that there is a conspicuous fall in the respiratory quotient at the time the increase of bicarbonate reserve is most rapid.

The above results form part of a larger scheme of research undertaken on behalf of the Medical Research Council.

## TRAUMATIC PARAPLEGIA:

OBSERVATIONS ON CASES WITH REFERENCE TO TREATMENT AND PROGNOSIS.

BY

O. H. GOTCH, M.B., B.Ch. Oxon., M.R.C.P. Lond.

THE object of this paper is to give an account of cases of paraplegia of traumatic origin with a view to establishing a rational treatment and prognosis. All the cases are collected together at the Queen Alexandra Hospital Home at Roehampton, and afford a unique opportunity for study.

It was rare before the war to meet a group of cases of uncomplicated traumatic paraplegia. The cases discussed in this report are all traumatic; all were young men when wounded, and their general health and strength at the time of the injury were apparently good. The belief is therefore warranted that most of the symptoms are purely the result of the spinal injury. It is possible, therefore, to draw conclusions as to treatment with reference to prognosis. In paraplegia following some particular disease this is not possible, since the pure picture of paraplegia is blurred in with the general symptomatology of the particular disease causing the paraplegia.

### Types of Cases.

The number of cases studied was 56, and the average age at the date of injury 21. All the cases when first seen had been wounded for three years, and some for five or six years. Of the 56 cases 39 were of the complete lesion type at the level of the fourth to tenth segments; 17 of the incomplete lesion type, ranging from the eighth to the lower lumbar segments.

In the cases with a complete lesion two well marked types can be distinguished—those with flaccid paralysis (paraplegia in extension) and those with spastic paralysis (paraplegia in flexion). Both types have an equal degree of motor and sensory paralysis extending as high as the original level of the lesion, but in the flaccid type there is a complete absence of all tendon and skin reflexes (with the exception of the anal skin reflex, which in a few cases is present). The lower limbs lie quite motionless, wasted, and shiny. The spastic cases, on the other hand, show an exaggeration of the knee-jerks (the ankle-jerks vary, and are occasionally absent), an extreme degree of ankle and patellar clonus, and a double Babinski response. The limbs appear very irritable to small stimuli; stroking or blowing on the skin surface will generally lead to involuntary contraction, the thigh becoming flexed on to the abdomen. A slight degree of irregular wasting of one or both limbs is to be observed, and the motor and sensory loss is as complete as in the flaccid cases. In both types there is complete loss of voluntary control over micturition and defaecation.

The cases exhibiting an incomplete cord lesion also fall into two types—the spastic and flaccid. The spastic cases have brisk tendon reflexes with pronounced double Babinski toe reflexes and ankle clonus, and the abdominal reflexes are absent. In one case, however, both upper and lower abdominal reflexes are briskly present, the Babinski reflex also being very pronounced. A certain amount of irregular wasting of the calf and thigh muscles may be present. The power of voluntary movement of the lower limbs is considerable, especially after

adequate massage, but walking is generally difficult, since so much energy is expended in overcoming the spasticity.

In the flaccid cases either all reflexes in the lower limbs are absent, or the knee-jerk is just elicitable in one or both limbs. The knee-jerk, if present, is not altered by reinforcement; one smart tap will elicit it, and a series of taps with the patient's hands clenched, etc., do not alter its character. The wasting may be very considerable, especially in the calf muscles, but the thigh muscles may be only moderately wasted. Systematic massage can improve this wasting very noticeably, but the neurological signs (that is, tendon reflexes) do not alter.

Voluntary movement varies. Most patients can stand and walk with aid, the motive power appearing to come from the muscles of the pelvic girdle. The loss of superficial sensation in the lower limbs is of a very patchy and variable nature, the majority showing an irregular riding-breeches anaesthesia with some patchy analgesia over the feet. The loss of muscle and joint sensibility is generally great, and nearly all the patients who can walk can only do so by looking at their feet; they cannot walk in the dark.

The bladder and rectal functions show a varying degree of departure from the normal. The majority of patients are aware of the desire to pass water and can control the passing of it—provided the bladder is not too full or the weather not too cold. Occasionally retention occurs, and a catheter has to be passed or retained for a few days. Five cases have almost normal bladder control but complete faecal incontinence, whilst three have no bladder control but normal rectal control. Sexual impotence is invariable. Priapism is common, and often a most distressing and, if there be obstruction to the circulation by a tightly fitting rubber urinal, a highly dangerous complication.

The blood pressure is within normal limits in all, and there is no difference between the arm and the leg readings.

### Special Symptoms in the Complete Type.

The symptoms now to be described are not as a rule found in the incomplete type of paraplegia.

Pain in the lower extremities is described as sharp, gnawing, gripping, burning, cutting, and is felt all down both legs; when very severe its onset is acute and there is a rise of temperature, though never above 101° in uncomplicated cases. There is no visible change of any kind in the physical signs. The patient is obviously in very acute pain, and is only relieved by hypodermic injections of morphine. A moderately severe attack is sometimes checked by aspirin, or better with salipyrin (gr. xx). The duration of these attacks is usually about twenty-four to forty-eight hours or less; if longer, some other factor is responsible, such as an old bed-sore which has become septic, or renal colic. The patients themselves ascribe these attacks to a change in the weather. I confess myself sceptical on this point, but cannot offer any adequate explanation as to the mode of origin of these pains. The symptoms suggest some irritation of the sympathetic nervous system, especially the pains described as gnawing and gripping, and may have an origin in the sympathetic ganglia outside the cord. Whatever the cause, there is no doubt that these limb pains form a very definite part of the syndrome of the complete type of paraplegia. Nearly all the patients complain of a continual sensation of tingling in the lower extremities, but this is not described as painful.

Flatulence is a very common and occasionally an acutely painful complaint. Well marked generalized abdominal distension with ladder-like peristalsis is to be observed, sometimes so great as to suggest definite obstruction. As a rule there is no vomiting, but constant eructations of gas and the passage of flatus per anum. The very severe cases look ill, and present a toxic appearance suggesting uraemia. These cases are relieved by a single injection of pituitary extract (posterior lobe, 1/2 to 1 c.cm.). The slighter cases, with moderate abdominal distension and pain, are often strikingly relieved by injections of mx of 1 in 1,000 liquor adrenalin. hydrochlor., or by double doses by the mouth in ice-cold water. An enema, either simple or mixed with asafoetida, does not appear to relieve

this condition, though, if given soon after the distension has disappeared, it will probably prevent a recurrence.

**Renal Colic.**—Typical attacks of renal colic are quite common, and occasionally the symptoms are bilateral. There is a decided tenderness in both loins, and usually in those cases of paraplegia that suffer frequently from such attacks a well defined mass in the position of the kidney is palpable. Several cases have shown very large irregular masses in both loins, which have been proved to be enormously dilated pelvises filled with pus and calculi, and surrounded by a grossly fibrotic kidney substance. The passage of blood-stained purulent urine usually follows after the attack has subsided, and may continue for several days.

**Chronic Urino-genital Sepsis.**—Under this rather cumbersome title I place all the complete paraplegics—that is, those patients with complete paralysis of micturition. Although the urine may appear clear and free from pus by gross tests, there is always present a cloud of albumin on boiling after adding acetic acid, and microscopically there is always evidence of a continually progressive breaking down process in the uro-genital tract in the shape of pus cells, bladder and renal epithelium, etc. At any time this process may become suddenly acute, resulting in a rapidly developing pyonephrosis, with an increasing mass in either loin, and high fever or cystitis, prostatitis, orchitis, or epididymitis. It is common to find a patient with no gross external evidence of an acute infective process, but with an irregular fever of months' duration, before the temperature finally returns to a normal level. I have regarded such cases as due to chronic sepsis in some portion of the uro-genital tract. I have often overlooked the prostate as the seat of infection in such cases, and in one case cautious prostatic massage led to the expulsion of a quantity of extremely offensive blood-stained pus, and the fever subsided. In massaging the prostate in these cases extreme care must be exercised, since if the massage be too vigorous a most alarmingly profuse haematuria will occur and take several days to subside.

**Uraemic Manifestations.**—Uraemia is the last stage in these cases. In a few instances it supervenes quite gradually without any very prominent symptoms. In one patient, who had been up and about for months, and seemed in good health and spirits, I noticed one morning that the respiration was peculiar, suggesting asthma. He said he felt very sleepy, but complained of no discomfort. The same evening twitching was observed, and coma rapidly supervened. No urine had been passed for twenty hours. Pilocarpine injections and hot packs were ineffectual. In other cases, however, the uraemic symptoms are most distressing, and continue for days; intractable vomiting and headache are prominent symptoms. The urine may show a practically normal measure or be entirely suppressed. I have never observed renal oedema of the eyelids, face, or back in any of these cases, and the eye-grounds have also been entirely normal, even in those patients who have shown symptoms of repeated slight uraemic attacks. The *post-mortem* findings are what one would expect. There is no naked-eye appearance of any true kidney substance. The kidneys are replaced by what looks like an irregular abscess cavity with fibrous walls, its interior filled with calculi and pus; the ureters are very much thickened, and occasionally filled with calculi. Slight cases of uraemia may recover under vigorous treatment (prompt injections of pilocarpine and hot packs, with abundant fluid by mouth), but I have not seen recovery in cases showing twitching even where the other symptoms are quite mild.

**Bedsore.**—These as seen in the cases under discussion are, for the purposes of treatment, conveniently divided into wet and dry. An old dry bedsore may remain stationary for years, and, unless very roughly handled, will not cause any trouble. A discharging bedsore, on the other hand, may defy the most energetic treatment in the shape of ointments, rest, and a variety of dressings and lotions, and get deeper and wider. I have no faith in any one particular line of treatment. I remember one patient who had had the most scrupulous aseptic treatment directed to a large extending bedsore with no avail;

finally it was decided to abandon the dressings and allow the bedsore to take its chance in a dressing largely composed of faeces; the result was complete healing within a few weeks. I can only attribute the healing of a bedsore to some personal factor in the patient, and assume that the reaction towards healing depends more on the general than on the local condition. As a rule dry dressings for dry bedsore and wet (preferably hot) dressings for wet sores give the best results. An extremely useful ointment for a clean but extensive bedsore which shows little sign of healing is that supplied by Messrs. Christy and Son under the trade name of "Sobrefacion."

#### General Treatment.

The incomplete cases with recovered bladder function show a gradual tendency to improve. Daily massage, systematic walking exercises, encouragement in self-confidence, all help this improvement. Such patients may with confidence be told that they will lead useful if restricted lives, and that no relapse need be feared. The completely paralysed patient, however, is in a different class. His progress cannot be other than gradually downward. Treatment, therefore, should be directed towards the retardation of that process as much as possible. Expert nursing, massage, and suprapubic drainage of the bladder are the essentials of treatment. I am convinced that the complete cases who have retained their suprapubic drainage apparatus have in all instances lived longer and have been very much freer from intercurrent symptoms than those without. Some of these cases with suprapubic drainage were wounded six or seven years ago and have hardly experienced the slightest discomfort. In patients with suprapubic drainage I have never observed any of the symptoms referred to above, such as acute pains in the lower limbs, abdominal distension, or intermittent fever of a severe and protracted nature. All the cases exhibiting such symptoms have either never had suprapubic cystotomy or the original suprapubic opening had been closed at some later date in their paraplegic history. Out of eight deaths two were in suprapubic cases, one of whom died of septic arthritis accidentally caused through injury; the other case died of uraemia.

There appears to be no doubt that as far as the patients' general condition is concerned suprapubic drainage has a great advantage over a closed automatically acting bladder. The bladder is washed out twice daily and the tubing changed. A solution of 1 in 8,000 to 1 in 10,000 potassium permanganate is the most effectual irrigating lotion. The best type of rubber drainage tube is an oesophageal tube. It is soft and does not cause trouble round the opening. For the complete cases I usually prescribe a routine mixture, to be taken thrice daily, of—

R. Urotropine	...	...	...	...	...	gr. x
Ammon. benzoat.	...	...	...	...	...	gr. xv
Tinct. hyoscyami	...	...	...	...	...	℥ xxx
Syrup. aurantii	...	...	...	...	...	5j
Aq. ...	...	...	...	...	...	ad 5j

Ammonium benzoate, when taken over long periods, does not cause digestive upsets like the acid sodium phosphate. The urine can generally be kept at a constant level of acidity by this therapy. I have found that tincture of hyoscyamus very appreciably diminishes the tendency to acute retention in cases without suprapubic drainage.

In cases without suprapubic drainage a retained catheter is used if there is a tendency to spasmodic retention. I have not found any harm result from employing a retained catheter for an indefinite period. The urethritis which may result can be quite easily controlled by sufficient lubrication of the catheter and irrigation of the urethra with 1 in 8,000 potassium permanganate solution.

Massage of the lower extremities, back musculature, and abdomen is absolutely essential in all cases of paraplegia, whether complete or incomplete. Without it the patient very quickly develops contractures, and bedsore on the feet appear; his general condition deteriorates, and he becomes very much weaker, so that he will be unable to sit up if he is a completely paralysed patient of a high level type. Massage should be given daily.

It does not appear to influence the acute pains in the lower limbs.

The importance of nursing in these cases cannot be overestimated. In fact, without the special care that the patients receive from the nursing staff at Gifford House I doubt whether any of the complete cases would be alive to-day.

#### *Prognosis and General Summary.*

In the complete cases the prognosis cannot be other than ultimately fatal, but in the absence of definite uraemic symptoms it is almost impossible to predict an immediately fatal issue. Even where a patient may seem semimoribund, with foul discharging bedsores, intermittent fever, and rapid general wasting, there is quite a chance that he will make a good recovery and be up in his chair again. A patient with extensiv osteomyelitis of the spinal vertebrae following a bedsores gradually pulled round and the condition entirely healed. On the other hand, I have not seen recovery following any uraemic nervous symptoms, even when the patient's general condition appeared quite good. It is always safe to predict rapidly developing coma and death when such symptoms exist. Acute haemorrhagic cystitis is always rapidly fatal; it may come on without any warning at any time during the patient's paraplegic life. I have seen two deaths from this condition, both in patients without suprapubic drainage. The mental factor undoubtedly plays a very large part in the grip that the patient has on life. A greatly depressing shock of some kind, the death of a friend, or serious trouble of any sort, will be sufficient to depress the patient's vital powers. He will become silent, depressed, refuse food, look increasingly ill, begin to develop bedsores, and may die if his confidence is not restored.

The main factors influencing prognosis appear to be:

1. Continued and skilled nursing.
2. Daily massage.
3. Establishment of adequate bladder drainage, preferably by the suprapubic method. Closure of a suprapubic cystotomy opening which the patient has had for some years and which is giving no local trouble is entirely contraindicated. This statement has been put to the test in five of the complete cases, and in all five symptoms have developed, such as bedsores, limb pains, fever, and malaise, which were not manifest previous to the closure.
4. Encouragement of mental confidence and mental occupation. In this respect an auto-wheel chair of special pattern has been found invaluable. It saves the patient any unnecessary friction, and enables him to get about and enjoy life, and generally assists him in forgetting the tragic aspects of his disability.

### A NOTE ON THE VALUE OF SYMPTOMS IN THE EARLY DIAGNOSIS OF PULMONARY TUBERCULOSIS.

BY

D. G. MACLEOD MUNRO, M.D., M.R.C.P. EDIN.,

DEPUTY COMMISSIONER OF MEDICAL SERVICES FOR TUBERCULOSIS TO THE MINISTRY OF PENSIONS.

THESE remarks are addressed primarily to the general practitioner, upon whose failure to diagnose pulmonary tuberculosis in its early stage some quite unjustifiable aspersions have been made from time to time. It is, indeed, encouraging to note how keenly the general practitioner has recently taken up this question and with what comparative success, especially on the lines of more recent views on physical diagnosis. It is not my intention to discuss this question from any original or novel standpoint, but I am inclined to think that we should seriously consider whether in this connexion the pendulum has not swung rather too far in the direction of diagnosis from purely physical signs.

The time is, I think, ripe to seek an adjustment of values between the two chief factors in the early diagnosis of pulmonary tuberculosis—namely, its symptomatology and physical signs. In a disease in which so many clinical and anatomical phenomena have to be correlated, and in which

the same individual may present a new symptom complex every few weeks, the position of the diagnostician is not always a happy one. It is only by painstaking adjustment of all the contributory elements in such cases and in the use of skilled judgement in interpreting the clinical picture thus presented that success will attend efforts to make a diagnosis in these difficult cases.

I am not aware whether it is still the rule, but until very recently I understand the diagnosis of pulmonary tuberculosis in the army was not regarded as established unless the tubercle bacillus had been found in the sputum; and it is not so many years ago that in civil practice the earliest recognition of the disease was based upon data which at the present time are considered to be the sign of a comparatively advanced stage. In auscultation, for example, it may not yet be generally appreciated that what is to be looked for is a change in the breath sounds of the *inspiratory* phase, which may be noted at a much earlier stage of the disease than alteration in the *expiratory* phase which may be present in many quite healthy chests.

The change of method in the elucidation of physical signs during the past few years has been, indeed, quite revolutionary, and thanks to Riviere and others, certain refinements in physical examination have materially assisted in the earlier recognition of the disease. The utility of inspection and palpation has been especially developed by the American school, and the value of these methods of physical diagnosis greatly enhanced. Hitherto inspection of the chest has been, from the point of view of the general practitioner, rather a perfunctory affair, and the virtues of palpation limited to vocal fremitus—now regarded as of doubtful value as a diagnostic sign in such cases. Now that special attention is being paid to the muscle reflex which results in what is known as "lagging" (the presence of which, especially at an apex, strongly suggests active mischief, although percussion and auscultation may give no indication of this) inspection and palpation assume a more important place. The proper appreciation of this sign requires practice, but this is soon acquired.

The information conveyed by inspection in these cases may be greatly reinforced by light finger-tip palpation, by means of which evidence of localized reflex muscle spasm—especially as affecting the sterno-mastoid, the scaleni, and the upper pectorals—may be detected. The trained finger appreciates in such cases a sense of muscle resistance in contradistinction to the smooth and more elastic sensation of normal muscle tension. Then, too, trophic changes in the muscles of the shoulder girdle and the state of the subcutaneous tissues may be similarly recognized. In the opinion of some experts, indeed, light touch palpation has very largely replaced percussion as an aid to diagnosis.

The technique of percussion, too, has been much improved, and it is now generally recognized that to be of any real value, apart from other points of detail, percussion must be light. But this method of physical diagnosis still presents many pitfalls, and, apart altogether from the question of accuracy, it must be strongly affirmed that local changes in the percussion note, especially at the apex of a lung—even if the existence of such cannot be doubted—convey nothing as to the presence of an active tuberculous lesion, or, indeed, that the lesion, if such exists, is tuberculous at all.

In my opinion, too much attention in the matter of percussion has been focused upon the definition of certain areas of the chest wall called after some eminent authorities. It is questionable, for example, whether in the early cases of pulmonary tuberculosis now under discussion any appreciable change can be found to have occurred in Krönig's area of so-called apical resonance. In rather a different category are the "bands of impairment" in the percussion note first noted by Abrams. These bands are said to be purely reflex in origin and to be one of the earliest indications of active pulmonary tuberculosis. My own experience of this diagnostic sign is not extensive, but I confess that in a number of cases in which I have utilized this method of physical diagnosis I have never been able to satisfy myself as to the reliability of the results.

But if we may gratefully acknowledge that a great deal of useful work has been done by what I may perhaps refer to without offence as the "physical force" school, we must admit, I think, that on the question of the early diagnosis

of pulmonary tuberculosis they have of late held the field too exclusively.

Turning, then, to the symptomatology of the disease, we find that a toxæmic state, revealed in one form or another and in greatly varying degree, is to be regarded as a manifestation of active tuberculosis. Pulmonary tuberculosis, however, cannot be held responsible for every unexplained toxæmia, as the symptom complex of this condition is much the same whatever the source of infection, and the existence of localized infection such as sinusitis, tonsillar infections, oral sepsis, and bronchiectasis must be excluded.

The group of symptoms comprise malaise, lassitude, nervous instability, digestive disturbances, tachycardia, fever, and night-sweats. I propose to deal in some detail only with two of the more prominent of the symptoms of the toxæmic syndrome, both of which on accurate observation will be found to present certain features characteristic of tuberculosis. These are (a) fever, (b) tachycardia.

#### *Fever.*

The presence of fever as an indication of tuberculous toxæmia is in this connexion of the greatest value, but certain qualifications are necessary if we are to arrive at trustworthy conclusions. It is unfortunate that temperature records are often taken in so casual a manner as to be practically valueless. It is not necessary, I think, to assume that a rectal temperature record is the only reliable method, more especially in private practice. If certain simple precautions are taken oral temperature records are quite trustworthy, except in the case of mouth-breathers. The thermometer should be retained in the mouth at least seven minutes; the temperature should not be taken immediately after the patient returns indoors after exposure to cold wind nor after partaking of a hot meal. It is not sufficiently recognized that the maximum temperature period varies greatly in different persons; to ascertain this period in a given case it is necessary to take the temperature every two hours. The first recorded temperature for the day ought not to be taken, as is often the case, after the patient has got up and dressed, but as early as possible in the morning before rising. The normal diurnal variation in temperature is about 1.5° F. In a majority of healthy persons the average early morning temperature is approximately 97.2° to 97.4° F., rising to a maximum of 98.6° F. in the early afternoon. This normal average is maintained by an equilibrium between the forces governing heat production and heat dissipation, and the entry of toxins into the blood stream, from whatever source, disturbs this balance. While it is not usual to find much temperature elevation in early pulmonary tuberculosis, it may be found that the early morning temperature is 98° F. and the maximum record for the day 99.2° or 99.4° F. The necessity for a continuous temperature record extending over three or four weeks in any case of suspected early tuberculosis will become apparent when it is pointed out that the toxæmic state is by no means constant; it ebbs and flows. The continuous temperature record therefore gives a fair representation of the degree of toxæmia present.

In chlorosis there is sometimes a slight average increase of temperature, while the premenstrual rise must not be overlooked. In persons of highly strung nervous temperament there are sometimes quite noticeable variations in the temperature curve. It will thus be seen that the process of elimination may have to be thoroughly invoked to clear the ground. Are there, then, any very clear indications, when all this has been done, which may point the way to a tuberculous toxæmia as the responsible source of the fever? I think there are. My own experience has led me to attach much importance to an early morning temperature—taken before rising—which is consistently a little above the average mean. The effect of a definite amount of exercise may be noted; while in a healthy person there is always a temporary rise—sometimes considerable—after exercise, this is usually quite evanescent, and within half an hour or so the temperature returns to normal. This is not so in the case of a tuberculous person. The decline of the temperature to normal limits is delayed and it may remain elevated for two or three hours. Hence the value of post-exercise temperature records in suspicious cases. Then, too, extraneous conditions resulting in emotional disturbance, worry, and anxiety;

which in a healthy person have no appreciable effect on temperature, may cause considerable disturbance in a tuberculous person. These features may be said to be characteristic of the tuberculous process. It will be seen, therefore, that fever, though still to be regarded as one of the cardinal points of the toxæmia of tuberculosis, cannot be accepted without due consideration of the qualifications outlined above, especially if there is no supporting evidence in other directions. It must be noted, however, that the absence of fever does not necessarily rule out the possibility of the existence of pulmonary tuberculosis.

#### *Tachycardia.*

From time to time I have seen patients found to be suffering from early pulmonary tuberculosis who have referred to an irregular and rapid action of the heart coming on without any apparent reason, but on the whole it has not been my experience that the cardiac disturbances caused by tuberculous toxæmia are noticed subjectively by the patient.

Tachycardia is of frequent occurrence in early tuberculosis—Fishberg puts it at 90 per cent. of incipient cases; it is hardly ever a subjective symptom. Like fever it is of toxic origin and appears to be the result of excessive stimulation of the sympathetic nervous system. The instability of the pulse in pulmonary tuberculosis would appear to result from a combination of vagus and sympathetic stimulation. Pottenger, who supports this view, considers that tachycardia as such is not a particular characteristic of active tuberculosis. In his opinion it is not regularly present unless the patient is in a depressed state, or has been over-exerting himself. This, I am inclined to think, does not fully represent the case. It is now, I believe, generally accepted that a pulse rate out of all proportion to any febrile condition present is a very common and reliable symptom of early tuberculosis in an active state, and further that the pulse rate may be notably increased on the slightest excitement or even after a fit of coughing. Another well marked characteristic is that, just as in the case of fever due to tuberculous toxæmia the fall of temperature is considerably delayed after exercise, so it is found that the increased pulse rate after exercise falls much more slowly than in health. I have repeatedly seen cases in which there has been persistent tachycardia, not referable to any cardiac abnormality or hyperthyroidism—a condition which is always to be borne in mind in the differential diagnosis—and in which the true diagnosis was only revealed by a sharp hæmoptysis. The physical signs in the chest in such cases may for a long time show no evidence of anything abnormal.

It has to be recognized, however, that pulmonary tuberculosis may masquerade as an affection of any of the great systems of the body with no signs or symptoms in any way directly referable to the lungs.

In none of the types of cases under discussion is it assumed that assistance can be sought by the presence of cough, sputum, hæmoptysis, pleurisy, or indeed any direct overt symptom. In such early cases radiography is of doubtful value and the complement fixation test is at times rather a blind guide. The key to the diagnosis is to be found more commonly in the history of the present illness, and inquiry cannot be too minute or painstaking.

### OBSERVATIONS ON A CASE OF MYASTHENIA GRAVIS.

BY

S. L. HEALD, M.D., F.R.C.S. EDIN.,

HONORARY PHYSICIAN, COVENTRY AND WARWICKSHIRE HOSPITAL;

AND

ARTHUR J. WILSON, M.B., CH.B. EDIN.,

HOUSE-PHYSICIAN, COVENTRY AND WARWICKSHIRE HOSPITAL.

THE following case, of a man in whom symptoms of this rare condition developed while he was serving in the army in the late war, and some six years before he attended this hospital as an out-patient, seems of sufficient interest to warrant publication.

The patient, a man 43 years of age, a painter by trade, first came under observation as an out-patient on December 13th, 1922, when he was complaining of muscular weakness and exhaustion and inability to swallow properly.

*Clinical History.*

The patient joined the army as an Al man in 1914. In 1916 he began to develop pain and weakness in the left shoulder and arm so that he was unable to lift things. His head began to feel heavy, and the muscles of the neck became so weak that he had difficulty in holding it up straight and it drooped downwards on to the thorax. He could not brace back his shoulders, which became rounded. His legs began to feel weak and heavy, and he was tired after a short walk. Shortly after this he had difficulty in articulation and he began to stammer. The upper eyelids began to droop and he developed a squint in the right eye which caused double vision. The lower jaw became weak, he had difficulty in chewing hard foods, and at the end of the day he was unable to close his mouth and the jaw drooped down, saliva dribbling from the mouth. Sometimes he had to hold his lower jaw up with his hand to enable him to masticate properly. In addition he complained of general weakness and unusual fatigue. He noticed that the quieter he was and the less he exerted himself the better and stronger he felt; thus at the beginning of the day the above symptoms were slight, but as the day wore on, especially if he had been exerting himself, they began to appear and reached their maximum intensity in the evening.

The symptoms used to disappear almost completely for intervals of a few weeks, during which he appeared to be quite normal, and then returned again, and a diagnosis of neurasthenia was made by the army doctors. Since that time the symptoms have become more marked, and in addition the patient developed difficulty in swallowing, the food regurgitated through his nose, and his voice became nasal. He had attacks of dyspnoea, especially during a fit of coughing. His legs became weak and he tended to fall.

*Clinical Examination.*

The striking thing is the facies, which is one of great fatigue or exhaustion, superimposed on a somnolent mask-like expression. The photograph shows the bilateral ptosis, the right external strabismus, the drooping of the jaw, and the general expression of exhaustion. The speech is normal in the early part of the day, but after much talking it becomes stammering and nasal in quality, those syllables which require complete closure of the nasopharynx by the elevation of the soft palate being pronounced with the greatest difficulty. The intellect and memory are normal and there are no emotional changes.

*Attitude.*—The body is bent somewhat forward, the head bowed down, the jaw droops, the lower lip sags down, and saliva dribbles from the angles of the mouth; the shoulders are rounded owing to weakness of the muscles which brace back the shoulders.

*Muscular System.*—No atrophy. The muscles are hypertonic and in a state of irritability. The patient states that he has experienced "twitchings" in certain muscles, especially after fatigue, particularly in the left masseter, lower eyelids, muscles of nape of neck, and in the thigh muscles. All the muscles show the myasthenic phenomenon—that is, at first the movement is performed perfectly,

but after being repeated it rapidly becomes slower and slower, and the extent of movement becomes diminished and is accompanied by severe pain; finally the muscle fails completely and after resting for a variable period recovery takes place; movement can then be resumed and the same cycle is gone through again. A curious phenomenon is seen towards the end of the voluntary contractions and is best observed in the masseter in the movements of opening and closing the mouth—namely, at the end of the last contraction the muscle passes momentarily into a state of painful spasm in which it cannot be voluntarily relaxed, and then it suddenly relaxes finally and completely, and passes into a state of paralysis. Thus the patient complains that, after chewing anything hard, his jaw soon becomes tightly clinched for an instant during which he cannot open it, and then it falls down "like a dead weight."

*Electrical Reactions.*—The reaction described by Jolly was obtained—that is, the muscles responded readily to the first few stimuli with the faradic current, then the contractions rapidly diminished in extent and ceased after a few minutes in spite of the continuance of the stimulus. After a period of rest, this myasthenic reaction was obtainable again; but this exhaustion of the muscles was not brought about by galvanism.

The superficial and deep reflexes are all exaggerated. The knee-jerk shows an alteration in type, the contraction appeared to be a summation of a series of superimposed small contractions. It was not possible to tire out the knee-jerks by repeated tapping of the patellar tendon for five minutes, though after the attempt the patient made the remark that he "felt as though he had just done a ten-mile walk." After this test the quadriceps muscle was observed to be in a state of coarse fibrillary tremor which the patient states is identical with that previously experienced in other muscles. Knee clonus is present. The pupils are equal and react to light and accommodation, and the fundi are normal. The right eye shows a permanent external strabismus, more marked in the evening, due to paresis of the internal rectus. Coarse lateral nystagmoid movements are present in both eyes. Deglutition, especially of solids, is difficult when the patient is fatigued, and

regurgitation through the nose then occurs. The palatal reflex is sluggish. There is no change in the organic reflexes. No sensory alterations in the nervous system are found. The blood Wassermann reaction is negative. Clinical and radiological examination of the thorax reveals no enlargement of the thymus gland, which is said to occur sometimes in this disease.

*Treatment.*

A prolonged course of treatment with strychnine alternating with pituitrin (hypodermically), thymic and thyroid extracts orally, was given, as recommended by those who suggest that myasthenia gravis may possibly be associated with disturbances in the endocrine system, but little improvement was noted. Most benefit appeared to result from absolute rest and the avoidance of all fatigue.

## HAEMORRHAGE FROM THE LARGE BOWEL CAUSED BY AN ADHERENT APPENDIX EPIPLOICA.

BY

R. ECCLES SMITH, O.B.E., F.R.C.S. EDIN.,

BARRY, GLAMORGAN.

In the *British Journal of Surgery* (July, 1922) Mr. Duncan C. L. Fitzwilliams recorded a case of a hernia involving an appendix epiploica, which became strangulated in a hernial sac, giving rise to urgent symptoms, but without the classical features of a strangulated hernia. Within the last year two somewhat similar cases were referred to me; the symptoms resembled subacute strangulation of a hernia, recurring at intervals, followed by the passage, after each attack, of a quantity of bright blood by the rectum.

The first patient was 54 years of age, and the possibility of a growth of the lower bowel was entertained by his medical attendant. The second patient was about 30 years of age, and the diagnosis was obscure, the presence of a polypus or adenoma of the lower bowel being suggested. In neither case were haemorrhoids present, nor did examination reveal any growth of the lower bowel, so far as could be ascertained by the finger or the sigmoidoscope.

In the first patient there was a hernia on the left side, which troubled him by coming down only occasionally, so that he did not wear a truss. In the second case the hernia was on the right side, and again was apparently of such a nature that he did not trouble to wear a truss. The symptoms in each case were very similar. The onset was

with a fairly severe pain in the lower part of the abdomen, followed by vomiting and by colicky pains for a short time. Within sixteen to twenty-four hours bright blood was passed per rectum, beginning with anything up to two ounces; it ceased in the next thirty-six hours. In each case the attacks came on while the patient was engaged in somewhat laborious work.

The diagnosis of a partial strangulation of the large bowel, of the Richter type, was given without much difficulty in the first case, where the hernia was on the left side, the bleeding following on the congestion of that part of the pelvic colon which had been partly strangulated and had escaped back into the abdomen. The second case was a little more obscure until a bismuth enema had been given. This showed plainly that the pelvic colon was lying right across the abdomen and appeared to be fixed near the region of the internal ring on the right side. A similar diagnosis was therefore made.

At operation in each case it was noted that an appendix epiploica of the pelvic colon was fastened to the fundus of the hernial sac; the neck of the sac was not unduly wide. There can be no doubt that the fixation of the appendix epiploica from time to time dragged a part of the pelvic colon into the sac, causing a partial strangulation of this viscus after the manner of Richter's hernia, giving rise to haemorrhage from that part of the bowel, after its escape, by rupture of some of the congested vessels consequent upon the reaction of the bowel. Radical cure of the hernia with removal of the offending appendices epiploicae entirely removed the repeated attacks of partial strangulation and the loss of blood from the lower bowel.

## MEDICAL, SURGICAL, OBSTETRICAL.

## MEAT POISONING IN JERUSALEM.

DURING the period January 5th to 11th, 1923, five families, comprising in all fourteen persons, were attacked with what appeared to be symptoms of food poisoning. The symptoms in each case were practically identical—initial chill, fever, gastro-intestinal disturbance, vomiting, colic, and diarrhoea, while in one or two of those affected nervous symptoms and collapse occurred.

The investigations made by Dr. MacQueen, A.P.M.O. Jerusalem, finally revealed the origin. He prepared a list of those suffering, and a list of the articles of food eaten by them during the three days prior to the onset of symptoms. It was found that each one of the patients had partaken of one thing in common—pork sausage—and, further, that each of the families had purchased portions of the same sausage at the same shop, but on different dates.

The ages of those affected ranged from 5 to 53. The time elapsing between the eating of the sausage and the appearance of the symptoms varied from four to seventeen hours; the average interval was seven hours.

In the case of a woman, aged 55, death supervened; she partook of the sausage on January 11th at 12 midday, showed first symptoms at 2 a.m. the next day, fourteen hours later, and died at 8 p.m. on that day, eighteen hours after the onset of symptoms. *Post-mortem* examination was not allowed.

On January 12th two samples of pork sausage were submitted to me from the District Health Office. One sample was taken from the portion left over from the sausage partaken of by a family then suffering, the other from the portion of sausage still remaining unsold in the shop where all the affected families had made their purchase.

Portions of the suspected sausages were removed, and after suitable treatment and preliminary enrichment in dulcitol peptone water, the growth resulting was transferred to plates of MacConkey's bile salt lactose neutral red agar. Colourless colonies picked off after twenty-four hours were transferred to agar slopes. Fermentation reactions of the organism isolated showed it to belong to the *Salmonella* group; the splitting of dulcitol was, however, considerably protracted. There was no indol production.

Tests were then made with the agglutinating serums made from *B. paratyphosus* B, *B. suispestifer* (*aertrycke*), and *B. enteritidis* Gaertner, prepared by the Lister Institute. The organism under investigation was strongly agglutinated in high dilution by the Gaertner agglutinating serum.

Inoculations of guinea-pigs with an emulsion of the organisms caused death, and *post-mortem* examination showed the presence of haemorrhagic enteritis.

The biochemical and agglutination reactions of the organism recovered from the spleen, liver, and lungs were those of *B. enteritidis* Gaertner.

In my opinion, despite the fact that I was unable to investigate the condition of the patients themselves from the bacteriological point of view, this small outbreak owed its origin to the toxin of *B. enteritidis* Gaertner.

G. STUART,  
Assistant Director of Health (L),  
Government of Palestine;  
Director Public Health Laboratories.

INVERSION OF THE UTERUS TREATED BY  
HYSTERECTOMY.

A WOMAN, aged 27, admitted to the Jersey General Dispensary on July 7th, 1920, stated that she had begun to menstruate at the age of 15 and that the periods recurred fortnightly and were excessive; she was treated for anaemia, and after a year the function became normal. She had a bad attack of influenza in 1918, but no other illnesses.

On January 25th, 1920, she was delivered by forceps under chloroform; pains were very slight before the birth, but much more severe afterwards; there was not much haemorrhage. On the fifth day after confinement she had retention of urine, and on examination the uterus was found to be inverted, and was replaced without difficulty by the medical attendant. She had attacks of fever and faintness during the six weeks she remained in bed, but no haemorrhage. On her bed she vomited and fainted twice. Two

weeks later haemorrhage began; it was slight at first but increased with time until large clots were passed.

I first saw the patient on July 1st, when she complained of metrorrhagia; a soft mass was felt projecting from the os uteri which was taken for a placental polypus.

On July 8th examination under an anaesthetic revealed the true nature of the case; manual replacement was attempted but was found to be impossible. On July 10th laparotomy was performed, and even with the belly open it was found to be impossible to replace the uterine body; amputation was, therefore, performed through the neck of the uterus. The uterus was not enlarged.

On admission to the hospital, on July 7th, the temperature was 100° F., and remained constant till the time of operation. On July 12th it rose to 101° F., and remained at this level, with slight daily remissions, till July 21st, when it rose to 103° F. On July 22nd the temperature reached 104.8° F., and the patient was very exhausted.

On July 24th 30 c.cm. of polyvalent antistreptococcus serum was injected; the temperature rose to 106.4° F., but fell in four hours to 99° F.

For the following four days doses of 20 c.cm. of the serum were injected, the temperature varying between 104° and 98° F.; at the end of this period the temperature became approximately normal and remained so until her discharge on August 15th.

The remarkable features of the case are the absence of uterine enlargement, which was possibly due to the strenuous use of ergot before she came under my observation, and the absence of any marked anaemia.

Jersey.

J. J. W. EVANS, F.R.C.S.

## THE TREATMENT OF DENTAL CASES.

I VENTURE to publish this short account of two dental cases because medical students are taught very little about dental diseases or inflammatory conditions of the mouth and jaws due to dental trouble, yet dental surgery is a branch of general surgery in the same way as otology or ophthalmology.

## CASE I.

A girl, aged 17, complained of swelling and tenderness on the right side of the mandible. The swelling was inflammatory and the doctor she consulted advised poulticing. The swelling burst and a purulent discharge lasted for some time, but eventually healing took place; the scar, however, broke down again in a short time. A dentist who was then consulted came to the conclusion that the girl had originally had an acute alveolar abscess; a considerable area of bone had necrosed and fracture of the jaw had ensued. It took a dental surgeon and a general surgeon over eighteen months to get the patient's chin into correct alignment, and the girl was left with a considerable amount of facial disfigurement.

The mistake here was the applying of fomentations to the outside of the patient's cheek. This practice is mistaken, and invariably leads to a certain amount of disfigurement, and sometimes to even more serious results. Dental students are taught to apply fomentations to the outside of the jaws only in exceptional circumstances. In the above case, if the doctor had had the tooth extracted at once and ordered hot mouth-washes every few hours, the necrosis and disfigurement would not have occurred. It is a sound principle to treat practically all inflammatory swellings of the jaws due to dental sepsis by hot frequent mouth-washes, after, of course, treating the cause. By this method the pus, if any, is drawn into the mouth, and so facial disfigurement is prevented. The exceptional circumstances I refer to are those cases in which the patient is obviously very ill from toxic absorption and drainage is needed at once. In these cases it is better to incise the swellings from the outside.

## CASE II.

A woman, aged 50, had been treated for about twelve months for gastritis and intermittent swelling of the joints. In six months her weight fell from 15 st. 2 lb. to 11 st. When I saw her the mouth was extraordinarily clean and healthy for a woman of her age; one or two teeth were missing, but the remaining teeth were clean, strong, and free from caries, and the gums were very healthy. There were three roots present which appeared healthy; the gum was tight and healthy round them, there was no pocket, and the root canal had calcified. I extracted these three roots and found that each of them had a chronic abscess sac at the apex. I prescribed a hydrogen peroxide mouth-wash and told her to return in a month. She was then a different woman; she was cheerful, was putting on weight rapidly, and had had no swellings of the joint since the date of the extractions.

This case is quoted because more harm is caused to the general health by such chronic abscesses than by chronic infection around the necks of the teeth, the pus from which

drains into the mouth. The chronic abscess being under pressure, infection gets directly into the blood stream, and so lowers the patient's whole vitality. This patient's mouth looked quite clean except for these roots, and admittedly even the roots appeared healthy. Her doctor might have suggested that she should have the roots extracted, simply because he knew it is the general rule to get rid of roots, but he would not be likely to think that the whole trouble could be due to the presence of the roots.

J. JAMES, L.D.S., R.C.S.Eng.,  
Dental Surgeon to Rotherhithe Hospital;  
Late Demonstrator, London Hospital Dental School.

#### SPONTANEOUS RUPTURE OF THE UTERUS.

A NATIVE woman, aged 29 years, was admitted to hospital in a very weak state, having been in labour for twenty-four hours at her home; she was in a state almost of collapse, and had intense abdominal pain. The appearance of her abdomen was quite abnormal—the outline of the child was easily felt and could be moved about, but this caused great pain, and the case appeared to be either extrauterine pregnancy which had gone to full term, or a ruptured uterus. As her condition was so bad I decided to wait until she rallied. On September 3rd, 1922, I opened the abdomen and found that it was a case of ruptured uterus; the child—full term and well developed—was lying dead in the abdominal cavity amongst the intestines, the placenta partially extruded from a transverse rupture of the uterus. The uterus was sutured and the abdomen closed; I brought the uterus forward and sutured the uterine wound to the abdominal incision for fear of accidents. The patient recovered very slowly, and I discovered that she was suffering from ankylostomiasis; the uraemia and general weakness rapidly cleared up after giving her chenopodium oil, and she was discharged well on October 17th.

C. M. ROLSTON, F.R.C.S. Edin.

### British Medical Association.

#### CLINICAL AND SCIENTIFIC PROCEEDINGS.

##### CAPE OF GOOD HOPE—WESTERN PROVINCE BRANCH.

A MEETING of the Cape of Good Hope—Western Province Branch was held at the New Somerset Hospital, Cape Town, on April 13th, with the President, Dr. CHARLES M. MURRAY, in the chair. He announced that two demonstration rooms would be conducted simultaneously, the one medical and the other surgical. Mr. C. C. ELLIOTT took charge of the surgical room and Professor A. W. FALCONER of the medical room.

Professor Falconer conducted the medical section to his wards, where he demonstrated cases of amoebiasis, gummatous meningitis, and cerebellar tumour. Dr. D. P. MARRAIS showed a case of Addison's disease. Dr. A. REITH FRASER showed a case of granuloma inguinale and one of digital chancre. Mr. D. J. WOOD showed an interesting series of eye conditions, including trachoma, spring catarrh, tubercle of the conjunctiva, chalazion, and an unusual example of glaucoma in a child aged 7.

Mr. C. C. ELLIOTT demonstrated cases of depressed fracture of the skull, depressed fracture of the supra-orbital ridge, malignant growth of the lower eyelid with the operation result, and an operated case of excision of the Gasserian ganglion. Mr. H. A. MOFFAT showed an old dislocation of the head of the radius, a tuberculous elbow, a fracture of head of the radius, and a fractured carpal scaphoid. Mr. C. F. M. SAINT showed an unusual case of psoas abscess with superimposed pneumococcal infection, a duodenal ulcer which presented a difficult diagnostic problem, and a tuberculous shoulder-joint. Radiographs were exhibited by Dr. H. W. REYNOLDS, including several interesting fractures, bone grafts, and cervical ribs. Professor E. C. CRICHTON demonstrated pathological specimens.

The PRESIDENT thanked Dr. A. Carrington Seale and the hospital staff for organizing the meeting and for entertaining the Branch.

## Reports of Societies.

### ULCERATIVE COLITIS.

A MEETING of the Subsection of Proctology of the Royal Society of Medicine was held on May 9th, under the presidency of Sir CHARTERS SYMONDS. Ulcerative colitis was the subject of discussion.

Sir HUMPHRY ROLLESTON, after referring to Sir William Hale-White's early description of the disease, asked what the term "ulcerative colitis" might mean. Ulceration due to amoebic or bacillary dysentery, to parasites, to known poisons, and so-called asyrum colitis (which was often epidemic and appeared to be bacillary dysentery) should be excluded. Ulcerative colitis did not appear to be a disease in the strict sense of the term, but a syndrome with fairly constant structural changes and clinical manifestations. Bacteriologically it was not a specific disease, for it might be due to a colon organism, to *B. pyocyaneus*, to the pneumococcus, streptococcus, or other organism. Some cases beginning as dysentery might cease to show the characteristic organisms in the faeces and become chronic ulcerative colitis. After death, as shown in a case of Dr. McNee's, the organism was still present in the wall of the colon. The opportunities for secondary infection of the colon were most favourable, and various organisms, especially of the colon group and streptococci, might appear to be the responsible factors for the condition. Bacteriological diagnosis of an acute colitis, such as the haemorrhagic type of pneumococcal origin, was less difficult than that of chronic ulcerative colitis. It was possible that a devitaminized diet, as suggested by McCarrison's and Findlay's experiments, might so lower the resistance of the patient, or change the type of organism, as to favour the onset of the disease. There was no proof that ulcerative colitis was related to swine fever. Was the type of the disease changing? It seemed to the speaker that perforation was less frequent now than thirty years ago. Stricture of the colon was rare. Leucocytosis appeared to be inconstant and inquiry as to a relative lymphocytosis was desirable. Sir Humphry Rolleston referred to the diagnosis of the ulceration, which was indistinguishable from that of amoebic dysentery, by the sigmoidoscope and x rays. For treatment a sufficient diet should be given. Drugs were not very successful; neither kaolin nor paraffin was completely satisfactory. Injections from below did not clear out the colon as did irrigation by means of appendicostomy. The relative values of appendicostomy, valvular caecostomy, colotomy, ileo-sigmoidostomy, ileostomy, and ileostomy with a separate appendicostomy, were briefly discussed. Vaccines had not enjoyed a very pronounced success. The use of anti-dysenteric serum, advocated by H. P. Hawkins in 1909, had been dramatically successful when given intravenously by A. F. Hurst, but, as evidence that the patients had bacillary dysentery was not forthcoming, it would be interesting to speculate if normal horse serum would not have been equally efficient.

Sir THOMAS HORDER remarked that he might have made more dogmatic statements with regard to this condition ten years ago. In his experience ulcerative colitis was found more commonly in women. Of ten recent cases eight were in the female sex; of five hospital cases only one was a male. The disease favoured young middle age—25 to 35. Among etiological factors he would mention enterotoxins, circulatory factors, and infections. Some of the patients would be found to have a cardiac lesion dating from an infection. With regard to bacteriology he would have said that streptococcal infection—not only *Streptococcus faecalis* or *viridans*, but also long-chained streptococci—should have come first, with the colon bacillus much later. He would mention certain clinical points. There was often an intense degree of anaemia. The spleen was sometimes enlarged, and this might be due to an infarct that did not suppurate. The liver might be enlarged. In one case in which he had had the opportunity of seeing the organ during caecostomy it was pale and fatty and reached nearly to the umbilicus. Within two months of the operation it had gone back to its normal level. The condition tended to recur. The doctor was often called in after there had occurred many attacks. Quite a number of people having normal-looking stools

suffered from chronic ulceration. When the physician thought he had cured the patient and looked through the sigmoidoscope, frequently there were still many ulcers present. What determined recurrence? He thought that ulcerative colitis was not so much a disease of the colon as a disease of the patient. It was a condition due to low resistance, as were phthisis and malignant endocarditis. With regard to treatment, if the patient were in such a condition that operative treatment must be tried, the colon might be drained by an appendicostomy or a caecostomy. If this had already been done he recommended treatment as for pulmonary tuberculosis, in bed, and in the open air. The diet should be the fullest the patient could comfortably manage without increasing the diarrhoea. A milk diet, not including casein, should be increased to a full diet; it should not be kept as low as possible. Tonics were useful. Vaccines could be used as supplementary treatment; he did not rely upon them. To sum up, the condition was a disease of low resistance. General methods of treatment should be adopted, supplemented perhaps by appendicostomy. There must be a long convalescence; for three months after the patient was up and about there should be no return to work.

Mr. P. LOCKHART-MUMFERY said that when the condition was discussed in 1909 there was a mortality of 50 per cent. Now the mortality had gone down to 15.7 per cent. Ulceration of the colon might be slight and localized to a few small patches or might involve the entire colon. The bacteriology of the condition was still very vague. Secondary infection was common. The paratyphoid group was often present, sometimes with and sometimes without streptococci. There were, he felt, great possibilities in the future for appendicostomy with replacement of organisms. He agreed that at present vaccine treatment was of little effect. The disease was one of early adult life; the average age was 32. The sex incidence was about equal. Diagnosis was by the sigmoidoscope. Stricture of the colon after the condition was very rare. There were more cases of this complication after caecostomy than after appendicostomy. An advantage of appendicostomy was that it could be done under local anaesthesia. The appendix should not be opened till the abdominal wall was healed. A catheter ought to be tied into the appendix. The fluid introduced should be at body temperature. The best he had found to be hypertonic solution of sea-salt. Weak silver solutions and solutions containing oil were sometimes successful. The appendicostomy should be performed early, and it should on no account be closed for a year. The patient should be warned of the danger of recurrence.

Dr. W. E. CARNEGIE DICKSON said that even if the ulceration should be due originally and primarily to one specific type of organism it speedily became a mixed infection in which a whole series of bacteria took part in attacking the bowel wall. Consequently it was generally necessary to treat the condition as one of mixed infection. It was important to remember this in treatment with vaccines or serums. In some forms of bacillary dysentery in which a vaccine made from the dysentery bacilli might not be suitable because of its great toxicity the specific serum might with advantage be used along with a mixed vaccine made from the organisms of secondary infection. In the old days it had been his custom to prepare a vaccine from some single organism which was thought to be the primary or the chief infective agent. He now used a widely varying series of culture media and from them, by selection, obtained a bacterial emulsion approximating to the organism found in direct films. A bacteriological report founded upon a single agar plate of the faeces was of little value and might be quite absurd. His own practice was to put on as a routine a series of agar, blood agar, broth, blood broth, anaerobic meat broth, litmus-milk, MacConkey lactose agar, and sometimes other media; and there were extraordinary differences in the variety and number of the various organisms grown from faeces in these different media. From them one might average up the results of the whole investigation. A bacteriologist needed three weeks, a month, or more to isolate his organisms in pure culture and give them long enough in the differential media to be certain of their biological reaction. Cultures after a week or longer showed a very different picture from that after three days, which was about the time a physician usually had to make his report. *B. pyocyaneus*,

difficult to recognize since it needed such copious supplies of oxygen to bring out its characteristic pigment, he regarded as being of great importance. Septic foci, especially in septic teeth, tonsils, nasal sinuses, and the appendix must be constantly remembered. In his own series of blood counts in such cases the speaker had usually found a leucopenia, the diminution affecting especially the polymorphs and thus producing a relative lymphocytosis and a secondary anaemia, especially a haemoglobinemia. He agreed with Sir Thomas Horder in the occurrence of leucopenia in very chronic streptococcal and in coli-typhoid-paratyphoid infections. He had also observed that injections of normal horse serum in such cases of leucopenia often brought about a rise to normal of the leucocytes or even a distinct leucocytosis.

Professor L. S. DUNCAN's paper was read in his absence. He was opposed to the view that ulcerative colitis and true dysentery were of necessity caused by the same specific organism. He felt that in all cases diagnosed as ulcerative colitis the following lines of investigation should be followed: (1) examination of the bowel by means of the sigmoidoscope; (2) bacteriological and protozoological examination of material from the floor of the ulcer or ulcers; (3) repeated examination of faeces; (4) examination of blood, more especially in relation to the presence of immune substances in the serum.

Dr. A. F. HURST said that Vedder and Duval, working under Flexner in 1902, found that epidemics of dysentery occurring in American institutions were caused by *B. dysenteriae*, and two years later Eyre showed that asylum dysentery in England was also caused by this organism. All attempts to isolate the bacillus from sporadic cases had failed, though in a small number of cases the blood had been strongly agglutinated by Flexner's bacillus. In diagnosis a growth within reach of the finger must first be excluded; then the sigmoidoscope should be used. Amoebic dysentery must still be considered even if examinations of the stools had been negative. He had seen a few cases in which this infection developed in England. An anaesthetic was only rarely necessary. The passage of the instrument did not cause pain unless the anal canal was inflamed, in which case a cocaine semple should be introduced a quarter of an hour before. If the sigmoidoscope were carefully introduced under visual guidance without inflation there was no danger. The few cases in which perforation had occurred had all apparently been due to the blind passage of the instrument. In ulcerative colitis the mucous membrane was bright red and thick; it bled easily when touched, and its surface was covered with blood-stained purulent mucus. The swelling of the mucous membrane was particularly noticeable in the normally thin Houston's folds. Ulceration might be slight or very extensive. Sometimes small islets of mucous membrane were left which, on rectal examination, might feel like small flat polypi. It was easy to mistake the floor of the ulcer for the surface of the mucous membrane. The ulcers were superficial, and had irregular, but not undermined edges. Their floor appeared greyish-yellow when wiped free from blood and mucus. The rectum and lower part of the pelvic colon were sometimes inflamed alone, but it was doubtful if the proximal part of the colon was ever involved without the pelvic colon and rectum. The differences between the sigmoidoscopic appearances of the mucous membranes in amoebic and bacillary dysentery were very marked; but the appearance of the mucous membrane in bacillary dysentery was indistinguishable in life, as Wilks had observed *post mortem*, from that of the sporadic ulcerative colitis occurring in England. In amoebic dysentery small round red elevations were seen on the otherwise normal-looking mucous membrane, corresponding to the collection of broken-down material in the submucous tissue caused by *Entamoeba histolytica*. In the centre of each elevation was a depressed yellowish ulcer caused by the rupture of the submucous abscess through the mucous membrane. The speaker had obtained remarkably good results through the intravenous injection of large doses of polyvalent antidysenteric serum. These results were not due entirely to the use of horse serum, but were definitely specific. In one similar case he had tried large doses of horse serum. No improvement resulted, but the administration of antidysenteric serum after a week's interval led to the usual

rapidly favourable results. He generally began with an injection of 40 c.c.m. intravenously, followed on consecutive days by injections of 60, 80, and 100 c.c.m. It might be necessary to repeat the maximum dose two or three times. A rise in the patient's temperature, a profuse erythematous rash, pain and swelling in the joints, often indicated a severe reaction which usually only lasted a few hours and never longer than a few days. The reaction was less likely to occur if 15 grains of calcium lactate were given three times a day the day before and during the days of treatment. Precautions against anaphylaxis were taken in patients who had previously had serum or in one who was subject to asthma. He had used this treatment in about ten cases. Very rapid improvement had always occurred, though in one case in which appendicostomy had been performed some months before it was incomplete. A secondary streptococcal infection had apparently become grafted upon the original dysenteric infection, as complete recovery only took place after the removal of the teeth, which was followed by a temporary severe local reaction. An attempt to treat this patient with a vaccine prepared from streptococci isolated from the stools had to be given up owing to the violent reaction which followed the injection of only a quarter of a million bacteria. His colleague, Dr. J. A. Ryle, obtained an equally satisfactory result in one case under his care. The treatment failed in two, but in both of these he recognized the ulcerative colitis as being of a hypertrophic character quite different from the ordinary type, so that in all probability it was caused by a different infection. One of these cases died shortly afterwards from perforation, which rarely, if ever, occurred in the usual form of ulcerative colitis, and in the other an appendicostomy, which was subsequently performed, led to no further improvement. In most cases the improvement was as rapid as that of amoebic dysentery with emetine, and epidemic bacillary dysentery with intravenous antidyenteric serum. In his first case the patient was so ill when he first saw him that he advised an immediate appendicostomy. In spite of this he went steadily downhill, and a fortnight later, when the first injection was given, his condition appeared to be almost hopeless. But in three days the blood had disappeared from the stools, in five the sigmoidoscope showed that the mucous membrane was entirely free from ulcers though still a little red, and in ten days the stools were normal and the mucous membrane was perfectly healthy, though the ulceration before the first injection was the most extensive he had ever seen. Treatment by rest, diet, albargin injections, and charcoal was of great importance before the introduction of serum treatment, but recovery was very slow. He had been inclined, therefore, till three years ago to advise appendicostomy as an additional measure in all severe cases. Since he had used large doses of serum he had not found it necessary to advise appendicostomy in a single case, and only occasionally had he used albargin injections. There were some cases, as in the two of Dr. Ryle's, in which the pathology was different and in which other methods of medical treatment with appendicostomy would be required. No case could be regarded as cured until the sigmoidoscope showed the mucous membrane to be perfectly healthy. Then the stools must be kept soft by paraffin or saline aperients for several weeks until the newly formed mucous membrane had overcome its original vulnerability to mechanical irritation. The sigmoidoscope should be used by every physician.

Sir CHARLES GORDON WATSON felt that antidiphtheritic serum had not yet been given a fair trial. Appendicostomy was the operation of choice. If this operation was performed early enough it offered a sure cure. But on no account should the appendicostomy be closed too early. He preferred flavine for his washes. The primary focus should be carefully sought, and, if discovered, should be treated.

## TREATMENT OF DIABETES WITH INSULIN.

At a meeting of the Edinburgh Medico-Chirurgical Society on May 2nd, with the President, Sir ROBERT PHILIP, in the chair, a communication was given by Professor J. C. MEAKINS, in collaboration with Mr. W. ROBSON, Dr. C. G. LAMBIE, and Dr. H. W. DAVIES, on the treatment of diabetes with insulin.

Professor Meakins introduced the subject by describing the discovery of insulin, referring to the work of Scott, Banting, and Macleod. Mr. Robson then described in detail the chemical processes involved in the preparation of insulin, its chief sources being the pancreas of the ox, sheep, or pig. Dr. Lambie dealt with the effect on the blood sugar curve in animals and also with the standardization of dosage. In the experimental work rabbits were the animals employed. Charts were shown indicating the effects on the blood sugar curve of injections of insulin; where the blood sugar fell to about 30 mg. per cent. harmful symptoms, similar to those produced by an overdose in man, were observed; the animals became somnolent and developed twitchings, followed by convulsive seizures and coma. By the injection of glucose, 3 grams in 10 c.c.m. of water, these symptoms were speedily relieved, otherwise death occurred. As regards standardization of dosage, as there were no means of determining this chemically, it was necessary to rely on biological experiment. In animals, however, great individual variation in susceptibility was observed. To overcome this it was necessary to use at least three animals of the same weight and whose reaction had already been tested. The animal was starved for twenty-four hours preceding injection, and the blood sugar estimated immediately before and two hours after injection. The dose which produced convulsions within four hours or which would reduce the blood sugar to convulsive level was known as "one rabbit dose." This was equivalent to four "American" units. The human dose was two and a half rabbit doses or ten American units. Dr. H. W. Davies then showed numerous charts illustrating the effects of insulin with or without glucose on the blood sugar curve of normal man and of diabetics, and its effects on acidosis and lipaemia. In normal man ten units of insulin produced a comparatively small drop in blood sugar as contrasted with a marked fall in the diabetic, this last being accompanied by a pronounced rise in the alkali reserve. Professor Meakins then dealt with the effect of insulin on carbohydrate metabolism in diabetics, demonstrating how its administration increased the retention of carbohydrate. He also spoke of the possible dangers of the drug, if the blood sugar content were allowed to fall too low, this being indicated by somnolence, delirium, twitchings, followed by convulsions and coma. These symptoms were most apt to occur four or five hours after the previous meal, when the carbohydrate was used up and the effect of insulin remained. Relief was at once obtained by the intravenous injection of glucose. Patients going out should be warned of the nature of these symptoms, and be instructed to carry some carbohydrate with them—an oatcake or a lump of sugar would do. The importance of combining insulin with dietetic treatment was emphasized. Finally, the beneficial effects of treatment with insulin were mentioned. There was an increased sense of well-being and, apart from oedema, a prompt increase in weight. The introduction of insulin made operation on the diabetic possible.

The communication was discussed by the President, Dr. CHALMERS WATSON, and Dr. KEEPIE PATERSON.

## Organization in the Treatment of Lupus Vulgaris.

A communication was read by Dr. ROBERT AITKEN on the benefits of organization in the treatment of lupus vulgaris. Dr. Aitken mentioned that the difficulties of treating lupus were greatly enhanced by the lack of control over the patient. A clinic at which only lupus patients attended was instituted to minimize this difficulty, and the method of controlling the attendance of the patients was indicated. Such a clinic had advantages for the physician and also for the patient. The physician could compare the value of the various remedies more thoroughly, while the moral effect of such a clinic on the patient was hardly to be exaggerated. Another advantage was the ease with which other investigations could be carried out. The treatment carried out at the clinic was next described, special reference being made to tuberculin injections. The results of treatment at the clinic were gratifying, the greater number of the patients being much benefited even when the attendance had been only for a short time. Statistics of the cures before and after the institution of

the clinic were given. The communication was illustrated by lantern slides showing the results of treatment in a few representative cases.

The PRESIDENT agreed as to the value of tuberculin, and made a plea for the percutaneous method of administration. The paper was also discussed by Dr. FREDERICK GARDINER, who spoke of the use of the arc lamp, and by Sir NORMAN WALKER. The latter emphasized the importance of early diagnosis and of perseverance in treatment, and said that the patient must be impressed with the seriousness of the disease and required to attend regularly. He strongly condemned the employment of x rays in treatment.

### THE COLLOIDAL ALKALINE RESERVE OF THE BLOOD.

THE Section of Anatomy and Physiology of the Royal Academy of Medicine in Ireland met on May 4th, with Professor EVART, in the absence of the President of the Section, in the chair, when Professor T. H. MILROY read a paper on the colloidal alkaline reserve of the blood.

Professor Milroy said that it was well recognized that the main alkaline salt of the blood plasma was sodium bicarbonate and that the steady reaction of the blood depended upon the constancy of the ratio of the free carbonic acid to the bicarbonate. The means by which living organisms maintained this ratio had attracted much attention, especially in regard to the renal and respiratory regulator mechanism. In addition to these modes of regulation there was another which undoubtedly played an important part—namely, the colloidal alkali store of the blood proteins. Many years ago it was recognized that on passing carbon dioxide through blood serum, and still more when the gas was passed through whole blood, the alkalinity of the fluid was increased. This increase was due to the removal of base from the plasma proteins and especially from the acid groups of the haemoglobin molecules. In this way, from one litre of plasma might be obtained 0.01 M base, and from one litre of whole blood 0.025 to 0.03 M base. Just as carbonic acid could remove base from these sources, other weak acids, such as cacodylic and even boric, were effective. The amount removed followed generally the law governing the distribution of bases between the competing acids in homogeneous solutions. The avidity of the acids for base was determined by their acid dissociation constants and by their respective concentrations. The blood colloids were removed by a method of ultra-filtration through thin collodion plates under pressure. The ultra-filtrates so obtained were quite colourless and suitable for determination of the reaction by indicator and other methods, and were free from any disturbing effects due to proteins. For this investigation it was necessary to examine the ultra-filtrates of different blood specimens before and after the addition of different acids of various concentrations. The methods employed were explained and a brief account of the results obtained was also given.

The CHAIRMAN thanked Professor Milroy for his kindness in coming to Belfast to present his important communication to the members of the Academy. Professor PRINGLE, in discussing the paper, speculated on the influence of the permeability of the stroma of the red corpuscles in affecting the fixation of acids. Dr. FEARON considered the possibility of a Donnan membrane equilibrium effect interfering with the alkali values of the ultra-filtrates. Professor MILROY, in reply, explained that he had eliminated the permeability effect by working only with laked blood. By a comparison of various ultra-filtrates, he had satisfied himself that no error was introduced by a Donnan effect.

Professor E. A. WERNER read a note on the precipitation of urea from urine. He said that when an equal volume of strong nitric acid was added to a 2 per cent. aqueous solution of urea, 59.1 per cent. was precipitated on standing as urea nitrate. A 4 per cent. urea solution similarly treated yielded 73.7 per cent. of urea nitrate. On the other hand, many samples of urine containing 2 per cent. and upwards of urea yielded no precipitate of urea nitrate when similarly treated. This was probably due to the influence of urinary colloids, since a 0.2 per

cent. gelatin solution would retard the precipitation of urea nitrate. This suggested a possible method for the determination of the colloidal matter in urine. The communication was briefly discussed by Professor SCOTT, Professor MILROY, and Dr. SPEARES.

Professor PRINGLE showed an apparent case of multiple ova in a single Graafian follicle from a rabbit's ovary. Instances of two and three ova had been previously recorded, but the present follicle appeared to contain fifteen, which made him somewhat doubtful as to their true nature. Professor SCOTT told of an occurrence of double ova in single follicles in a rabbit he had examined some years previously, and outlined the probable embryonic cause of such a condition. He could not, however, account for fifteen.

Professor DIXON exhibited sections of the earliest human embryo which he had encountered. The chief structures were described and illustrated by microscopic preparations and by diagrams.

Dr. FEARON demonstrated the benzaldehyde test for tryptophane, which could be applied to all proteins containing that amino-acid.

### GALL STONES.

At a meeting of the West Kent Medico-Chirurgical Society at the Miller Hospital, Greenwich, on April 13th, Mr. C. A. JOLL delivered a lecture on the diagnosis and treatment of gall stones. They might occur at any age, and he had had six patients under the age of 22—the youngest was 14½ years, and she had been treated as a neurotic for two years. Gall stones were common in the prime of life, and two-thirds of the cases were in women; frequently they were the result of infection. The symptoms were repeated bilious attacks, indigestion, flatulence, a feeling of undue fullness, nausea in the middle of a meal, sometimes a feeling of chilliness. The attacks had no relation to the time of taking any particular food. Half of the cases did not have biliary colic. Referred pain occurred at the point of the shoulder and the angle of the scapula, sometimes in the region of the lower right ribs. Robson's sign was elicited by standing behind the patient and pressing both sides under the costal margin, when pain occurred in the gall bladder. Jaundice was found in 21 per cent. of the cases. Pyrexia was uncommon, and when it did occur it was due to infection. In a small group of cases there was no pain, but obstruction came on suddenly; the gall stones in such cases were mostly single cholesterol stones unassociated with infection. Some cases had chronic indigestion and no pain, some had biliary colic only, some indigestion only. Medical treatment was futile. The intervention of the surgeon was necessary to prevent damage to the liver. Operation should be avoided in acute cholecystitis. Calcium was of use only when given intravenously; 5 c.cm. of a 10 per cent. solution was given for three days before operation. Drains should be inserted in all cases, and the cystic artery should be tied separately. Patients suffered no ill effects from the removal of the gall bladder; if it were left pain might return, but it should be left in chronic pancreatitis. Carcinoma was associated with stone. Drs. PURVIS, BUCHAN, HUDSON EVANS, PAYNE, KNIGHT, M. DAVIDSON, WHITE, BAIN, and QUINN took part in the subsequent discussion.

### CYSTOSCOPY AND PYELOGRAPHY.

A MEETING of the Liverpool Medical Institution was held on April 26th, with the President, Professor J. HILL ABRAM, in the chair, when Mr. F. STRONG HEANEY read a short paper on cystoscopy and pyelography. Mr. Heaney briefly reviewed the present position of cystoscopy and pyelography in the diagnosis of diseases of the bladder, ureters, and kidneys. He showed by means of a series of lantern slides how cystoscopy by itself excluded the bladder and localized one or other kidney as the active septic focus in certain cases of chronic pyuria. He pointed out that in the absence of tubercle bacilli in the urine cystoscopic examination in conjunction with clinical signs enabled one to make a definite diagnosis of tuberculous

kidney. The appearance at the ureteral orifice in cases of intramural ureteral calculus altered when the stone remained a considerable time *in situ*. In some cases of hydronephrosis it was not possible, he said, to demonstrate the condition by aspiration, whereas a pyelogram might successfully overcome the difficulties of diagnosis. In cases of obstruction the appearances of the ureterogram or pyelogram varied according to the level of the obstruction. He showed how a ureterogram differentiated between a phlebolith or mesenteric gland and a ureteral calculus, and how the normal pyelogram enabled one to exclude the possibility of a kidney condition in favour of other intra-abdominal lesions.

Mr. J. ST. GEORGE WILSON read a note on bronchopneumonia in a stillborn foetus associated with maternal death.

The mother was a 14-para, aged 49; all previous labours had been normal. The membranes ruptured thirty hours before the onset of labour, and the first stage occupied three hours. Forceps extraction failed. As the cord was prolapsed and pulseless the foetus was perforated, but there was still failure to deliver. The mother died five and a half hours after the onset of labour, owing to shock.

The foetus weighed 4.72 kg.; bronchopneumonia was demonstrated in both lungs, and streptococci were found in the alveoli and cultured from the spleen. The reaction in the lungs was so marked that the inference drawn was that pneumonia commenced before the onset of labour, and it was surmised, in the absence of post-mortem examination, that foetal infection was a contributory cause to, if not the sole cause of, the sudden death of the mother.

Dr. NORMAN B. CARON stated that caution was necessary in assuming that micro-organisms found in a foetus which had died during labour were responsible for any pathological lesion discovered. This was especially true when perforation had been performed.

Dr. J. MURRAY BLIGH read a paper on unexpected death in children. He discussed in particular its relation to lymphatism and the clinical signs indicative of that condition.

## Reviews.

### DISEASES OF THE GUMS AND ORAL MUCOUS MEMBRANE.

IN *Diseases of the Gums and Oral Mucous Membrane* Sir KENNETH GOADBY summarizes the results of many years of clinical and laboratory observation and research. It is interesting, therefore, to find him emphatically endorsing the opinion that "pyorrhoea alveolaris" is primarily a disease of the gums, owing its initiation to infection of the gum tissue around the necks of the teeth, and beginning as a mild but chronic infection of the gingival margin. He does not, however, belittle the predisposing factors. On the contrary, arguing from the analogy of scurvy, beri-beri, and rickets, and from the alveolar bone and gum changes found in dogs fed on a "deficiency diet," he is inclined to credit vitamin deficiency with an important part in the production of pyorrhoea. The suggestion may be valuable, but so far it is only a suggestion, and the author has not attempted to indicate where the deficiency is to be looked for, although he refers specifically to peeled potatoes.

Throughout the book there are frequent proofs of originality of thought and close clinical observation. As instances of the latter we may quote his description of the gums in lymphatic leukaemia and of the mouth in sprue; as an instance of the former his interpretation of certain x-ray appearances may be cited, though it probably runs counter to the opinion of most radiologists. Pathologists may ask what is meant by "acute hypertrophic gingivitis."

The chapter on diagnosis contains many useful passages. Perhaps the most interesting is a table of blood counts contrasting the blood changes found in early suppurative periodontitis (pyorrhoea) with those found in later stages accompanied by periarticular rheumatism, or by rheumatoid arthritis. The author insists on the use of a hand glass in examining the gums, and on the value of microscope

smears to determine the origin of pus. In discussing disease originating from mouth affections the suggestion is made that, so commonly are joint diseases due to chronic streptococcal infections, were a satisfactory polyvalent antigen evolved vaccination against streptococcal arthritis would become as common as vaccination against small-pox. Considerable importance is attached to the use of an antigen prepared from the infecting mouth organism before any extraction of teeth, and cases of "delayed infection" are cited in which it is suggested that the explanation is a subinfection due to the extraction of teeth. Such cases might be avoided by previous immunization, but we do not get a very clear idea of how to select the proper organism from the brief account the author gives of this important point.

In the chapter on periodontal disease Sir Kenneth Goadby expresses strong dissent from the view that pyorrhoea is a disease arising around the apices of the teeth and of a non-inflammatory nature. The microscopical appearances which have been invoked in support of this view he finds equally explicable as the result of an irritant and compares them to the changes found in the tissues in the immediate neighbourhood of the advance of gas gangrene. He points out also that in the deep pockets of "pyorrhoea" there are always considerable numbers of anaerobic bacteria, especially bacteria associated with Vincent's angina or necrotic stomatitis.

Though, perhaps, interest and criticism will chiefly centre round the author's views on periodontal infection ("pyorrhoea" to the vulgar), there are other chapters also which will challenge attention. Those on ulcerations of the gums, on special diseases of the mouth and gums, and on diseases with oral symptoms are of great interest; they are all written from personal observation. It is not quite clear why tumours, both innocent and malignant, should be included under ulcerations of the gums, and it may be noted that a ranula has perhaps other modes of origin than a blocked sublingual duct.

Throughout the book will be found notes and indications for treatment which cannot fail to be of interest and use to the practitioner, dentist, or doctor dealing with the conditions described. We doubt, however, whether many will be found bold enough to follow the advice given on page 117, to make punctures with the electric cautery into the cancellous interdental bone for the cure of early patches of rarefying osteitis. The work of others is freely quoted and references given.

The book is rather marred by the not infrequent occurrence of somewhat obscure passages. We may cite "the tongue turns round and round in the minor axis of an ellipse, and its edges perform simple harmonic motion in relation to the position of the teeth"; and we may ask, how do inflammatory masses pass from the surface of a traumatic ulcer through the epithelium deeply into the tissues below?

But whatever its faults the book is well worth the attention both of the dentist and of the general practitioner.

### TROPICAL DISEASES.

WITH the appearance of Volume III, *The Practice of Medicine in the Tropics*,<sup>2</sup> edited by Lieut.-Colonel BYAM and Major ARCHIBALD, is completed. The text of the three volumes fills over two thousand five hundred pages, and in addition there is an Index of Authors and a General Index to each volume. An excellent portrait of Major-General Gorgas forms the frontispiece of the third volume, which contains also thirty coloured plates of considerable merit. A large number of authors contribute the different articles. To helminthiasis (Section XI) 280 pages is allotted, and as the subject is dealt with in considerable detail this is not too much, especially when we remember the many and various diseases to which infestation with worms may give rise. There may be some difference of opinion as regards the

<sup>1</sup> *Diseases of the Gums and Oral Mucous Membrane*. By Kenneth Goadby, K.B.E., M.R.C.S., L.R.C.P., D.P.H. Cantab. Oxford Medical Publications. London: Henry Frowde, and Hodder and Stoughton. 1923. (Roy. 8vo, pp. xvi + 383; 106 figures, 8 plates. £2 2s. net.)

<sup>2</sup> *The Practice of Medicine in the Tropics*, by many authorities. Edited by Lieut.-Colonel W. Byam, O.B.E., R.A.M.C. (retired), and Major R. G. Archibald, D.S.O., R.A.M.C. (retired). Volume III. Oxford Medical Publications. London: Henry Frowde, and Hodder and Stoughton. 1923. (Roy. 8vo, pp. xx + 335; 348 figures, 30 plates. Price of the complete work £4 4s.)

classification adopted and some of the names employed, but this was probably inevitable. In the section on disorders of metabolism is an article on deficiency diseases by Lieut.-Colonel Vedder dealing with scurvy, beri-beri, and epidemic dropsy. Apparently the right of pellagra to a place amongst the true deficiency diseases is still in doubt; it is discussed in a separate chapter by Dr. G. M. Niles, who is by no means emphatic on the subject, contenting himself with saying "the hypothesis that pellagra is caused by a deficiency is very plausible, and must be taken into consideration in subsequent studies of this disease." A chapter is given to typhus fever, though it is not strictly a tropical disease. In the section on diseases of doubtful causation a fascinating summary is given of the present state of knowledge with regard to *Rickettsia prowazeki*, and Dr. Byam in an interesting chapter on trench fever deals with bodies of this nature in their relation to that disease. The study of rickettsia bodies is full of promise and of great interest to all workers on these diseases. A chapter on another interesting disease, tsutsugamushi, or Japanese river fever, follows that on trench fever, and is from the pen of Professor Nagayo of the Imperial University, Tokyo. He states that the symptoms of the malady are suggestive of typhus and Rocky Mountain spotted fever, but present some distinct features. The nature of the causative agent is not yet established with certainty, though it is known that a mite *Trombicula akamushi* transmits the virus; the subject is illustrated by a very good coloured plate of the primary lesion or ulcer. The possibility that the disease is due to a rickettsia is not mentioned. Dengue and phlebotomus fever are classed among diseases of doubtful causation, and no mention as far as we can find is made of the *Leptospira hebdomadalis*, of Japanese seven-day fever, nor of Whittingham's discovery of leptospirata in phlebotomus fever. Perhaps the work went to press before these observations were published. The subject of diarrhoeas in the tropics is treated in the section on regional diseases, though why it should be placed here is not very clear. Ophthalmology, the heart in chronic tropical disease, skin diseases, and diseases of women are all dealt with. The section on surgery is illustrated by some wonderful photographs of tumours and of an extraordinary example of Egyptian splenomegaly. In such a large and massive work as this slight mistakes in spelling and so on are difficult to avoid, but on the whole they are wonderfully few, and those that have been observed are not perhaps of extreme importance. Contentious matters arise in some of the articles, but the authors may reply, "Quot homines, tot sententiae." The standard throughout the three volumes is of the highest and the articles have been written by men thoroughly conversant with the subjects they have dealt with. The work will, we believe, become the standard book of reference on the subject throughout the English-speaking nations. All that remains is heartily to congratulate the editors on the completion of their laborious though interesting task, and to assure them that the hope they express that they have compiled an authoritative work which will familiarize students with the names, work, and lines of thought of many of the leading tropical investigators is well founded.

*Framboesia tropica (Parangi of Ceylon)*<sup>2</sup> is the title of a useful little monograph on yaws, by Dr. R. L. SPITTEL, F.R.C.S., Surgeon to the General Hospital, Colombo. In the preface he states that it professes to be nothing more than a clinical study of framboesia, or parangi, as met with in Ceylon, and that historical and experimental data are omitted. There are no chapters nor index, the whole being contained in some sixty pages. Even so, an index would have been of value. The photographs of the disease are the main feature of the book. They are not only numerous but of excellent quality and illustrate the points of the disease in an admirable manner. Fig. 23 (p. 31) very much resembles gangosa, a disease not admitted by all to be tertiary yaws. Students of the subject will be interested in the book.

<sup>2</sup> *Framboesia tropica (Parangi of Ceylon)*. By R. L. Spittel, F.R.C.S. Eng. London: Baillière, Tindall, and Cox. 1923. (Demy 8vo, pp. iv + 59; 39 figures. 5s. net.)

The fifth edition of DANIELS and NEWHAM's *Laboratory Studies in Tropical Medicine*<sup>4</sup> is in its style and general tone unchanged, but the text has been revised and some new diagrams and figures inserted. The number of pages remains much as before, but there are now twenty-nine chapters instead of twenty-four, with an appendix. Two chapters are given to normal blood and its study, one to abnormal blood conditions, one to blood plasma and serum, and three to protozoa in the blood. The term "intestinal parasites" has been dropped; they are considered under the heading of helminthic parasites. Insects are dealt with in eight chapters, and the last chapter is a survey of malaria. It will thus be seen that a large amount of material is dealt with, and in fact the realms of bacteriology, protozoology, helminthology, and entomology are all explored in a more than cursory manner. The work is intended especially for the student taking out the course at the London School of Tropical Medicine, and for those preparing for the Diploma of Tropical Medicine and Hygiene. In such a work the greatest accuracy is necessary, as otherwise mistakes may be perpetuated. An analysis of many of the scientific names that occur throughout the text shows that the rules of zoological nomenclature have not been strictly adhered to. Most of these lapses, which will grieve the purist, occur in the part dealing with the helminths. *Schistosoma* is rendered *Schistosomum*—a mistake; *buski* should read *buskii*; *Taenia echinococcus* (p. 304) should be *Echinococcus granulosus*; *gnathostomum* should read *gnathostoma* (p. 33); and the name *oxyuris* has been changed to *enterobius*. The generic name of the chigger is now, as pointed out by Rothschild, no longer *dermatophilus*, but *tunga*, and so on. The method of performing the Wassermann reaction described on pages 112 to 118 is not one of the four standard methods recommended in the Medical Research Council's report on the subject; one or all of these should be given in a future edition, so that the worker may make his choice of an accurate and thoroughly reliable method. In future editions it would, we think, be an advantage to put the headings in darker and heavier type, as this expedient would render it easier to pick up and remember the special points. The chapter on intestinal protozoa is now illustrated by Dobell's figures of the intestinal amoebae and flagellates, which are, of course, excellent; there are also many other diagrams and some useful coloured plates. There is room, then, for improvement in certain directions, for a student's handbook should be, above all things, strictly accurate, and it is with the intention of helping the authors that we have made these observations. Speaking generally, the new edition is a thoroughly practical guide to the student of tropical medicine and is sure to maintain the popularity previous editions have enjoyed.

#### THE BLOOD SUPPLY TO THE HEART.

AN inquiry into the circulation of the heart in its relation to age periods and pathological variations has led Dr. Gross, in his monograph entitled *The Blood Supply to the Heart*,<sup>5</sup> to present us with a work that has outstepped its original limits, and to supply us with many facts which have a very definite clinical bearing.

The author has developed a technique for the preparation of his specimens which has given excellent results, if we may judge by the numerous photographs which illustrate the book. For general purposes barium sulphate gelatin has been used as the injecting medium, after which the hearts were x-rayed, then cleared, finally dissected and sectioned. For special purposes, as for the capillaries, carmine gelatin has been used. Full details of the methods are given.

Two chapters deal with the blood supply to the auricles and ventricles. The supply to the auricles is specially prone to variation, so that the picture of the average

<sup>4</sup> *Laboratory Studies in Tropical Medicine*. By O. W. Daniels, M.B. Camb. F.R.C.P. Lond., and H. B. Newham, O.M.G., M.D. Durh., M.R.C.P. Lond., D.P.H. Camb., D.T.M. and H. Camb. Fifth edition. London: John Bale, Sons and Danielsson, Ltd. 1923. (Demy 8vo, pp. xiii + 576; 184 figures, 7 plates. 25s. net.)

<sup>5</sup> *The Blood Supply to the Heart*. By Louis Gross, M.D., C.M., Douglas Fellow in Pathology, McGill University. Oxford Medical Publications. London: Henry Frowde, and Hodder and Stoughton. 1923. (Imp. 8vo, pp. xvi + 171; 29 plates, 6 figures. 25s. net.)

auricular supply cannot be given. Thus in 44 per cent. of cases both auricles received their chief supply from the right coronary; in 36 per cent. from both coronaries; and in 20 per cent. from the left coronary. The supply to the ventricles is more constant, though no clear line of demarcation can be drawn owing to the overlapping of the arteries and to the profuse and abundant anastomoses. In general the right coronary supplies the whole of the right ventricle with the exception of the left third of the anterior wall, and also the right half of the posterior wall of the left ventricle and the posterior part of the intraventricular septum. The left coronary supplies the remainder. The blood supply to the neuromuscular tissues receives separate attention. A special supply is described, though the supply from the two coronaries is variable. Thus the *s-a* node is supplied by the right vessel in 60 per cent. of the cases, while the *a-v* node, the bundle, and main branches receive blood from the same vessel in 92 per cent. of the cases.

The subject of endocarditis is illuminated by the author's study of the vascularity of the valves and the discussion of previous work along similar lines. It is shown that the vascularity and musculature of these structures diminish as age advances, and few cases have been injected after the age of 30 years; the aortic cusp of the mitral valve is the last to lose its blood vessels; in foetal hearts the blood supply is greater on the right than on the left side. A discussion of the possible connexion between these facts and the relative frequency of valvulitis in early life, the special liability of the mitral valve to be affected, and the right-sided valvular defects of the newborn, is very suggestive, more particularly when related to the view that the infection comes by the coronary supply.

The blood supply of the heart at different ages is discussed, and some interesting facts are brought to light. Dr. Gross sees in the increasing vascularity of the adipose tissue as age advances something approaching a compensatory mechanism, as it may function as a source of supply to the underlying muscle.

The illustrations are very well produced, but just because of the wealth of detail a pointer in some of them would have added to their value. The book will take its place among the classics in this subject.

#### A CONSTELLATION OF THE NORTH-EAST.

In *Viri Illustres Universitatum Abredonensium*,<sup>6</sup> W. E. McCulloch, himself a medical alumnus of the ancient seat of learning, has compiled a little volume that every Aberdeen graduate and student should have in his possession, if for nothing else than to remind him—if so be he needs the reminder—that he is one of a goodly company. Dedicated "To my Fellow-Students," the volume opens with a modest preface in which our compiler, after due acknowledgements to the University librarian, Mr. P. J. Anderson, and Professor J. Arthur Thomson, states that, having considered biographical notices of about 700 of "our graduates, alumni, and teachers," he has only included some 280 of these in his final selection. For inclusion in the list he has applied the tests: "Did the subject lead? Did he set men thinking? Did he add to the sum of human knowledge or help to preserve it?" And Mr. McCulloch further states that he looks on his work as "merely a stop-gap until some graduate shall arise who will devote the requisite energy and ability to the full unfolding of these half-cut pages in our great records." But he may rest content, meanwhile; for he has well and truly laid the foundation stone of that granitic edifice which he hopes later to see rear its head.

The biographies are assembled under four headings—Science; Theology; Literature, Art, and Philosophy; and Public Services. Medicine, for some obscure reason, is slumped in along with Science—all the more strange as Theology is deemed worthy of a section to itself; but this may simply be an evidence of the hereditary, ingrained Scots respect for the pulpit. Amongst his medical men he deals with John Abercrombie (1780-1844), a native of

Aberdeen and M.A. Marischal College, 1800, the famous teacher in the Edinburgh medical school; Francis Adams of Banchory-Ternan (1796-1861), M.A. King's College, 1813, the well known country practitioner and classical scholar, to whom "Rab" pays a glowing tribute under "Our Gideon Grays" in *Horae Subseivae*; his son Andrew Leith Adams (1827-1882), M.A. 1846, M.B. 1848, F.R.S., who, after serving in the Army Medical Service, became Professor of Natural History at Queen's College, Cork; Sir Andrew Clark (1826-1893), M.D. 1854; Sir James Clark (1788-1870), an alumnus 1803, and M.A. (hon.) 1848, Physician in Ordinary to the Queen (Victoria), and to whose advice is ascribed her purchase of Balmoral; Sir Patrick Dun (1642-1713), alumnus Marischal College, 1658-1660, a native of Aberdeen who went to Dublin in the far-off days when the expectation of life in that city was longer than it is now, and became its leading physician and President of the Irish College of Physicians; James Matthews Duncan (1826-1890), M.D. 1845; the academic Gregories, of whom James *secundus* (1753-1821) and John (1724-1753) were Professors of Medicine in Edinburgh after being teachers of medicine in Aberdeen; Sir James Mackintosh (1765-1832), M.A. Marischal College, 1784, and M.D. Edin., 1787, who forsook medicine for law, was recorder of Bombay, and later a Liberal M.P.; Sir Patrick Manson (1845-1922); Sir James McGrigor (1771-1858), M.A. Marischal College, 1783, M.D. Edin., 1884, Director-General of the Army Medical Department, 1815-1851, whom Wellington called "one of the most industrious, able, and successful public servants" he had ever met; and William Pirrie (1817-1882), M.A. Marischal College, 1825, M.D. Edin. 1829, the immortal "Baron" of much legendary lore, who was first Professor of Surgery at Aberdeen.

This little book deserves to have a wide circulation, not only in "Aberdeen an' twal mile roun'," but also amongst the many, born or educated there, who have migrated beyond the sacred radius.

#### VITAMINS.

THE large number of books dealing with vitamins and nutrition which have appeared recently may be divided roughly into two classes—reference works for research workers, and semi-popular works intended for those without special knowledge of the subject. *Vital Factors of Foods, Vitamins, and Nutrition*, by Mr. ELLIS and Professor ANNIE MACLEOD, one of the biggest volumes on the subject that has yet appeared, seems to be an endeavour to combine the two classes. The authors refrain as a whole from expressing their own opinion on problems, but give short statements of the results obtained by various authorities. This method unfortunately makes the book rather difficult to read, for the general result is somewhat reminiscent of a card-index. This must reduce the value of the book to those without special knowledge of the subject, more particularly as authorities disagree on an unfortunately large number of matters regarding vitamins; the general reader is not assisted by learning that a certain number of authorities believe one thing and an equal number believe the opposite.

From the point of view of the research worker the book suffers from the drawback that it contains very little about the work done during the last two years. This is, of course, an inevitable disadvantage attending the writing of a large book on a rapidly changing subject. The larger the book the longer it takes to prepare, and the more certain it is to be partially out of date by the time it is published. In the present case this is a rather serious disadvantage, for the present output of vitamin literature is something like one article a day, and about one-third of the total literature on the subject has appeared since the beginning of 1921. The book contains an appendix of thirty-four pages summarizing the evidence as to the distribution of vitamins in foodstuffs; about three hundred references are given and only about twenty of these refer to papers published in 1921 and none to papers published in 1922.

Similarly, in the chapter devoted to rickets we found no

<sup>6</sup> *Viri Illustres Universitatum Abredonensium*. Compiled by W. E. McCulloch. Aberdeen: W. and W. Lindsay. 1923. (Demy 8vo, pp. xvi + 175. Cloth, 4s. 6d. net; paper, 3s. 6d. net.)

<sup>7</sup> *Vital Factors of Foods, Vitamins, and Nutrition*. By Carleton Ellis, S.B., F.C.S., and Annie L. Macleod, Ph.D. London: Chapman and Hall, Ltd. 1923. (Med. 8vo, pp. xiii + 391; 22 figures. 2s. net.)

mention of the very important recent work upon the influence of light on this disease, which has made it necessary to revise many of the conclusions previously arrived at concerning the relation between vitamin lack and the occurrence of rickets. It may be replied that as it is obviously impossible to write a completely up-to-date textbook upon such a subject as vitamins, it is therefore unnecessary to lay too much stress upon the points mentioned above, but we feel that the volume under review rather falls between two stools; it is too much a summary of conflicting opinions to be of great service to the general reader, and the fact that it contains so few recent references reduces its value as a book of reference for research workers. The writers of the book are chemists, and it is therefore not surprising that the best chapters are those upon the stability, chemical structure, and methods for the concentration of vitamins. In the chapter devoted to "Concentrated preparations of vitamins" several proprietary preparations of vitamins are mentioned; the authors might have been rather more cautious in accepting the claims made for some at any rate of the preparations mentioned.

The chapters devoted to the action of vitamins in disease contains a good summary of the knowledge available down to the middle of 1921. In the chapter "Vitamins for the Baby" an account of the vitamin requirements of infants is given, but we are surprised to read the statement (p. 295): "In spite of the somewhat conflicting evidence it seems justifiable to conclude that a healthy child can develop normally on an exclusive diet of cow's milk, whether raw, pasteurized, dried, or condensed, provided a sufficient quantity can be fed." Presumably the word "exclusively" means without the addition of fruit juice, and while we are not prepared to assert that it is impossible for a healthy child to develop on an exclusive diet of condensed milk, yet we believe that the available evidence is practically unanimous in indicating that on such a diet scurvy or rickets will probably develop.

As we have indicated, there are numerous points in this book open to criticism, but it may in conclusion be said that the authors have succeeded in compiling an immense mass of material, and that those interested in research in vitamins will find in this volume a large amount of valuable information, particularly in the chapters dealing with the chemistry of the vitamins.

#### SURGICAL PATHOLOGY.

*Grundriss und Atlas der allgemeinen Chirurgie*,<sup>a</sup> by Professor Dr. GEORG MARWEDEL, dedicated to Professor Dr. V. Czerny, is a short textbook dealing with surgical pathology and bacteriology. It is well illustrated, containing about 30 coloured and 200 ordinary illustrations. We observe that many of these show advanced stages of disease, seldom seen clinically nowadays. Whether they have been copied from old textbooks is not stated, but if not they seem to suggest either that the early treatment of disease as a whole does not penetrate the remoter strata of the Bavarian populace as it does in this country, or that it is more conservative.

In the chapter on sepsis and antiseptics special emphasis is laid on the work and teaching of Lister. Under anaesthesia all the ordinary methods are discussed; cocaine is recommended for local anaesthesia, and tropacocaine for spinal anaesthesia. It is interesting to note that the gas and oxygen method is not mentioned. Wounds of all kinds are discussed in detail. The question of shock and haemorrhage is dismissed in a few pages. Saline infusion and blood transfusion are mentioned, but it is disappointing to find no account of the research work on this subject during the war. Fractures are treated with plaster and (according to the diagrams) by a complicated series of weights, pulleys, extensions, and counter-extensions.

The classification of tumours in many respects differs from ours. Among the fibromata are included the hard and soft varieties, the mollusca fibrosa of von Recklinghausen, keloids, and the various forms of elephantiasis. The illustration of "Kolossales Lipom des Nackens" rather

suggests a Tyrolean mountaineer with a permanently adjusted rucksack. The malignant tumours are classified into the sarcomata and carcinomata; among the former are grouped the peritheliomata, endotheliomata, and melanomata. Three varieties are given—the round, spindle-celled, and the myeloid. This grouping of the myeloid sarcomata is interesting because no reference is made to the non-malignant variety, although treatment by local resection is advised. Sarcomata of bone are divided into periosteal and myelogenous varieties. Rodent ulcers are placed among the carcinomata.

It is a pity that political venom should make its way into textbooks. Two spiteful references are made to the "disgraceful hunger blockade." It is regarded as a cause of non-puerperal osteomalacia and rickets, these various bone lesions being grouped under the heading of "Hunger Osteopathies." The greater incidence, severity, and mortality of the various forms of tuberculosis during the war is ascribed to the same cause.

#### NOTES ON BOOKS.

THE appearance of the fifth edition of CROSSEN'S *Diseases of Women*<sup>9</sup> is a satisfactory indication of the continued popularity of this book. In the reviews of the early editions we have indicated the main points of the work and expressed our high appreciation of its worth. The author in the present edition has subjected the text to extensive revision and has endeavoured to bring up to date the discussion of the x-ray and radium treatment of malignant disease, fibroids, and other pelvic conditions. There is also an interesting exposition of the employment of x rays in diagnosis by means of pneumoperitoneum, a method which is in vogue on the other side of the Atlantic for the moment, but which will probably disappear for all cases except some of sterility in which the patency of the tubes is dubious. Recent advances in pathology have also been incorporated in the text, as, for example, those with regard to the connexion between "endometrial" cysts of the ovary and adenomyomata or "endometriomata" of the recto-vaginal septum and elsewhere. Dr. Crossen's book is very beautifully produced and profusely illustrated, and we are confident that this edition will be as successful as its forerunners.

The forty-second volume of the *Transactions of the Ophthalmological Society of the United Kingdom*<sup>10</sup> comprises the proceedings of that society during its forty-second session, together with reports of the proceedings of the Oxford Ophthalmological Congress, the Midland Ophthalmological Society, the North of England Ophthalmological Society, the Irish Ophthalmological Society, and the Ophthalmological Society of Egypt. At the session of the Ophthalmological Society of the United Kingdom in May, 1922, the chief discussion was on industrial diseases of the eye, to which Dr. T. M. Legge, Mr. A. Bernard Cridland, Professor Edgar Collis, Mr. N. Bishop Harman, and the late Mr. Charles Killick contributed papers. The feature of the Oxford Ophthalmological Congress in July, 1922, was the discussion on the significance of retinal haemorrhages, opened by Dr. C. O. Hawthorne and Mr. P. H. Adams; the important paper contributed by Dr. Hawthorne was afterwards published in full in our columns (*JOURNAL*, September 16th, 1922, p. 495). The Doyne Memorial Lecture at the Oxford Congress was delivered by Dr. J. Burdon-Cooper, on the etiology of cataract. An interesting discussion also took place there on methods of operating for cataract, to which Sir Anderson Crichtett, Colonel Smith, Dr. K. K. Lundsgaard, and Mr. T. Harrison Butler contributed. The volume contains also reports of ophthalmological cases and pathological observations contributed to the various affiliated societies. There are many excellent illustrations.

*Flowers and Fancies*<sup>11</sup> is the title of a pleasant little book of poems by Mrs. CELESTINE LAVENS WEST, who shows a decided leaning towards the less elaborate forms of versification. The poems are marked by sincerity and sympathy, and their subjects cover a wide range—the countryside of Staffordshire and Northumbria, the fancies of children, Michael Collins, Einstein's theory of relativity, the seasons, and metempsychosis.

<sup>9</sup> *Diseases of Women*. By H. S. Crossen, M.D., F.A.C.S. Fifth edition, revised and enlarged. London: H. Kimpton, 1923. (Sup. royal 8vo. pp. xxx + 1005; 924 figures, 1 plate. 50s. net.)

<sup>10</sup> *Transactions of the Ophthalmological Society of the United Kingdom*. Vol. XLII. London: J. and A. Churchill, 1922. (Demy 8vo, pp. xlix + 409; illustrated. 30s. net.)

<sup>11</sup> *Flowers and Fancies*. By C. L. West. London: A. H. Stockwell, 1923. (Cr. 8vo, pp. 42. 3s. 6d. net.)

<sup>a</sup> *Grundriss und Atlas der allgemeinen Chirurgie*. Von Professor Dr. G. Marwedel. Zweite vermehrte und verbesserte Auflage. Munich: J. F. Lehmann, 1923. (Cr. 8vo, pp. xii + 454; 201 figures, 32 plates.)

## THE VOLUNTARY HOSPITAL SYSTEM.\*

BY

SIR RICHARD LUCE, K.C.M.G., C.B.,  
SENIOR SURGEON, DERBYSHIRE ROYAL INFIRMARY.

I HAVE chosen the subject of the Voluntary Hospital System because the maintenance of our hospitals is one of the most pressing social questions of the hour, and one which vitally concerns, not only the medical profession but the whole body of the community. No one who concerns himself at all with social matters can fail to be interested in the future of the hospitals.

The title "*Voluntary Hospitals*" has come gradually into use without any very exact definition of its meaning having been laid down. It has come to be applied generally to those hospitals which are supported by voluntary contributions as opposed to those on the one hand in which the patients pay for the treatment they receive, and those, on the other, which are supported by State or local government funds. It does not necessarily mean that all the work done in them is unpaid work, or that there are no patients in them who do not contribute to their maintenance.

The origin of these hospitals is largely lost in the mist of history, but with few exceptions they sprang up through the country during the latter end of the eighteenth or beginning of the nineteenth centuries by the benevolence of charitably disposed persons to provide that medical care and treatment which the necessitous poor could not provide for themselves in their own homes. With them came to be associated, in the larger centres, the medical schools in which medical students, no longer content with the training they could get by apprenticeship to older practitioners, could obtain organized instruction and practical experience under trained teachers of high repute. It became the recognized custom for a medical student during part of his curriculum to "walk," as it was called, one of the larger hospitals. Gradually as the State assumed control of medical education certain of these hospitals became the sole recognized places for the provision of the more professional parts of a student's training.

The control of the hospitals was vested in a body of governors, who were subscribers of a certain sum annually or donors of a lump sum, who themselves appointed a committee of their number to carry on the management. In those hospitals where any of the subscriptions come from the working class it has become usual to have representative governors for these subscribers and a definite representation of them on the board of management.

In the by-laws of most of these institutions there was originally a clause to the effect that only the necessitous poor were eligible for treatment. In our own Derbyshire Royal Infirmary, by a recent revision of the rules, it has been thought well to omit this clause. Since the foundation of the hospitals times have changed.

The advances of medical science have introduced many complicated and expensive forms of treatment, which can only be carried out in an institution fitted with costly apparatus, controlled by specially trained doctors, nurses, and assistants. Moreover, specialism in medicine has advanced to such a degree that a large number of diseases can now only be satisfactorily dealt with by the co-operation of several men who have made a special study of different branches of the work. Thus a surgeon, before undertaking a grave operation, often requires the assistance of a physician to elucidate certain medical aspects of the case, a radiologist to make certain x-ray examinations, and a pathologist to carry out special tests as to the working of the organs to be dealt with. This co-operation of medical men, or "team work," as it has come to be called, is of course available in a fully equipped general hospital, but elsewhere can only be obtained by running about to a number of specialists, an expensive business, only within the reach of those who are well off.

Further, surgical technique has become so complicated that a surgeon is very unwilling to perform serious operations except under the best possible hygienic surroundings and in rooms specially designed for the purpose, and with the help of assistants who are accustomed to his particular methods. This means that most operations are now performed either in the hospitals or in nursing homes, which from administra-

tive expenses are within the reach only of the comparatively well-to-do.

It has become necessary, therefore, for the large bulk of the community and not only the necessitous poor to find a refuge for the relief of their graver ailments in the voluntary hospitals. At the same time changes have been taking place in the social outlook which affect the hospital question in various ways. It has gradually been recognized that the State has large responsibilities to its citizens. First, in the matter of education, then in sanitation and preventive medicine, and finally in the provision of medical care and support for the workers in ordinary sickness, the State has felt it to be its duty to take control and ensure that adequate provision is made for the needs of the community. The State has already made itself responsible to some extent for the treatment of infectious cases, for tuberculosis, for venereal disease, for school children, expectant mothers, and infant babies. These departments of medicine have been taken over by the State one after the other until, for the mass of the community, comparatively little besides the medical, surgical, and special treatment provided by the voluntary hospitals remains outside the control of the State or local authorities.

Another concurrent change is the altered eye with which the mass of the people regard so-called charity. The industrial class no longer wish to be the objects of charity from another class, and yet are forced to take advantage of the institutions which were started and long maintained by that class. The result is that the voluntary hospitals are no longer maintained by the rich as a charity to the poor, and all members of the community are now taking their share in the work. But since the money is given as a free-will offering and without any definite right to benefits conferred on the subscribers, the voluntary and charitable nature of the system remains. Naturally and rightly, with their increased share in providing the funds, the industrial classes have obtained a greatly increased representation in the management of the hospitals.

That the voluntary hospitals have done their work well and that they have become more and more popular with the public that use them, I think, incontestable. They have fulfilled their function with credit to themselves and with benefit to the community. It is no failure on their part that has brought about the present financial difficulties, under which a large proportion of the hospitals in the kingdom are now working with an annual deficit. They are only suffering with the rest of the world from the tightness of money and increased cost of living produced by the war. It is a crisis which is likely to break some of them or seriously curtail their capacity for usefulness unless active steps are taken to restore their financial stability.

The easiest way, though difficult enough under the present conditions of high taxation, would be to obtain the necessary funds from the revenues of the State or local authorities. In doing this we should only be following the trend of the times. It has already been done in education and in several departments of medicine.

*Arguments for and against State Control.*

My chief object in bringing this subject before you is to discuss whether such a method would be for the good of the community.

To begin I will refer to the possible advantages of such a remedy.

1. In taking over the responsibility of providing hospital treatment for all those who need it, the State would be compelled by public opinion to provide full accommodation in the hospitals for all who demand it. This cannot be said to exist at present, though by careful use of the beds we manage to carry on without any great hardship to the individual.

2. The hospitals themselves, relieved of the present burden of financial anxiety, would be able to devote themselves more whole-heartedly to their administrative work. The responsibility for finding the money would fall on the broad back of the Chancellor of the Exchequer. The hospitals would only be concerned in seeing how much they could get out of him.

3. It might be thought that under unified State control it would be possible to co-ordinate the various medical services into a homogeneous whole and do away with a certain amount of overlapping, rivalry, and waste. To the orderly mind of the professional administrator and to the political reformer this might seem somewhat of an advantage, though I shall hope to show later that it is not all gain.

\* An address delivered to the Derby Rotary Club.

4. The financial burden would be distributed fairly throughout the whole community, and not rest on the shoulders of the generous, though the degree of fairness would no doubt be viewed differently by individuals just as it is now in other forms of taxation.

5. It would no doubt be said by some, though I cannot altogether agree, that under State control a higher standard of efficiency could be obtained by a system of inspection similar to that obtaining in education.

Now for the opposite side of the picture:

1. The practice of medicine is a combination of an art and a science. It is based on scientific knowledge, and in recent years science has perhaps become the predominant partner, but it is still largely an art. A large amount of medical treatment is based not on exact scientific lines in which the correct treatment follows the correct diagnosis as a matter of routine in the way that an omelette is produced by the proper mixture and treatment of certain ingredients. It is largely a personal factor. The best doctor is one who, with a good knowledge of the recognized scientific facts, by his individuality and intuition is able to apply his scientific knowledge so as best to suit his own capacity and the characteristics of the patient. It is not a rule-of-thumb business which can be controlled by acts and regulations, but a skilful handicraft working largely empirically with a just regard to the qualities of both doctor and patient. We might conceive of a time when all medicine would be reduced to a dead level of science, but that time has certainly not arrived yet. The human body, its constituents and its vital processes, are in many ways too complicated for our present knowledge. We still must work largely in the dark. This is what I mean by the art as opposed to the science of medicine. Now art is a shy bird. It lives on freedom. It cannot endure being fettered by rule and harassed by control. It soon begins to wilt in captivity. Whenever arts have been bound by rule they have deteriorated. Whether it be in painting, poetry, music, or architecture, all progress stops when individual freedom is checked; and so it is with medicine. State medicine will never be progressive medicine. It is individualism and freedom that have brought about progress. With State control in medicine, as in every other department that the State has touched, a system of bureaucratic control, both financial and professional, will inevitably be introduced. People will not work honestly for the State unless they are watched. The State does not expect it. With inspection freedom and individual enterprise will to a large extent disappear and progress in medicine will cease, just as it disappeared years ago under the control of the Church. I know this is an argument against all State control in medicine, and you may say I am preaching a retrograde movement, but it is not wholly so. Most of those branches of medicine which the State has hitherto taken over are those in which control is least harmful and in which there are special reasons, such as the public safety, why they should be controlled; but it would be particularly harmful in those institutions which have led the way in the new developments of the science and art of medicine as the voluntary hospitals have done.

2. State medicine is extravagant medicine. Even an M.P. does not work for the State for nothing, and very few State workers will do more than they are obliged for their money—they get no thanks if they do. Not only must every worker be paid, but an army of paid administrators, inspectors, and financial controllers must at once be superimposed on the workers to see that they do their work and do not spend too much money. How does this compare with the present management of the voluntary hospitals? No one will, I think, deny that at present they are run very economically, and yet there is no stint either in the domestic or medical department. At the Derbyshire Royal Infirmary the staff of 100 men in my time of over twenty years, been refused any means of treatment or apparatus which they have asked for; but the staff, because they have had the financial interests of the institution at heart, have been careful and reasonable in their requests. From my experience of State hospitals I am afraid that under State control the medical staff is not likely to be much interested in the economical working of the institution. Then, in the voluntary hospitals, the vast proportion of the medical work has been done by the medical men. Under the State this certainly would not be so. Through their Medical Association they have already stated that they will not do so. The payment of the medical staffs must involve a great increase to the expense of running the hospitals under State control.

3. A cut-and-dried scheme of State hospital medical benefit designed to prevent overlapping, by which patients would be obliged to go into the institution provided for them in the area in which they live, would do away with that wholesome spirit of competition which does so much to stimulate

the flagging energy and interest. You will remember that one of the chief points which was fought for at the time of the inception of the Insurance Act was free choice of doctor, and there is no doubt that this is a most important factor in keeping the medical man up to the mark professionally. If it is true of the individual medical man, it is equally true of the medical institution and its staff. If the limit of area of the Derbyshire Royal Infirmary was absolutely fixed and there was no competition between Derby, Nottingham, Burton, Sheffield, and Manchester, or even between the various hospitals in Derby itself, an important item which works for efficiency would be lost. It is perhaps an admission of human frailty that this is so, but it remains a fact that without competition human effort flags and the quality of work deteriorates.

4. There is what I call the Argument of Sentiment. This is a prosaic world and we are supposed to be a prosaic people, but sentiment still occupies a large part of our lives, and especially so in matters of health and sickness. The craving for sympathy is inherent in the human race, and is never more present than in times of illness. There is no doubt about its efficacy in mitigating the pain and misery that sickness causes, nor about the help that human sympathy gives in the actual cure of physical and mental disorders. Anyone who has seen the craving of a wounded man in a far-off land to get back to England and his friends, and the glow of hopefulness that lights up his whole being when he knows that he has been marked for transfer to the United Kingdom, could not fail to be convinced of the real curative power that sentiment has with the sick. There is no doubt that the voluntary system in our hospitals fosters this spirit of sympathy in the community. Those who give voluntarily, whether it be of their wealth or of their time and thought, cannot fail to have their sympathies drawn towards those for whose benefit they are giving, and an atmosphere will be produced in which there will be a blessing both for him that gives and for him that takes. Into this atmosphere, with its spirit of kindness and charity, the sick will enter trustfully and without dread, and from it they come forth filled with a spirit of gratitude. I am not saying that in State institutions kindness and sympathy are not to be found, but I am convinced that it cannot be the same thing in them with human nature as it is. With the voluntary system there comes, too, the pride of possession to those who support the hospital. The voluntary donor feels a personal interest in it and likes to see it popular and efficient. He rejoices to see his hospital a credit to his town and county. This feeling reacts on the staff and is distinctly stimulating. One cannot help comparing the pride and affection with which our voluntary hospitals are regarded by a large section of the community with the atmosphere of business-like apathy which surrounds hospitals supported by taxation as they are in foreign countries.

#### *Can the Voluntary System Survive?*

These are, to my mind, unanswerable arguments in favour of a voluntary basis of maintenance for our hospitals, but of course they count for nothing if the goodwill and generosity of the community is insufficient to provide and maintain sufficient accommodation to meet the needs of those who require treatment. If the necessary funds are not forthcoming from voluntary sources they must be found by taxation. The work cannot stand still; hospital treatment has come to be a vital part of the life of the nation, and must be carried on in its interests. But it will be a bad day if the fountain spring of charity ceases to flow in sufficient volume to maintain and distribute its full measure of the healing fluid. If force has to be added to maintain the pressure, like all forced pressure it will be wasteful, extravagant, and harsh in its action.

The question is, therefore, whether it will be possible in the future to maintain these great and growing services on a voluntary basis. Have we reached the limit of what can be got by the free-will offerings of the people, or must the residue be extracted forcibly by legislation? In my opinion the answer to this question must be met by another question. Do the people of this country really want the voluntary system to continue? Do they realize the advantages of it from the point of view of what they get by it and what they have to pay, and that under the State they will have to pay more for an inferior article?

If they fully realize this and set about an effort to maintain the present system it can be done. In some places, in spite of bad trade and high cost of living, it is being done now, and these places are just such manufacturing centres as our own, with a large working-class population who believe in their hospital and have made up their minds that it shall go on.

At the end of 1921 the Derbyshire Royal Infirmary had a deficit of £7,000 on the year's working expenses, besides a considerable amount due on the extensive building scheme just completed. At

the end of last year not only was there no deficit on the year's working, but practically the whole of the previous year's deficit had been wiped out, and only a comparatively small sum was still due on the building fund. And how had this been done? Trade was bad; taxes were as high as ever. It was the working men's contribution. They decided that the voluntary hospitals were necessary to them and they found the extra money. It was found with enthusiasm. With the increasing subscriptions the interest in the institution has spread widely.

It is evident that here, at any rate, the voluntary system is popular with the industrial classes. But though the maintenance of the hospitals on a voluntary system is now assured in most large industrial areas, it is not so everywhere, and a system of this kind must stand or fall by its weakest members.

It may be worth while to consider the views of some of the various groups in the State concerned with the question of the voluntary hospitals.

#### *The Cave Committee's Report.*

The Minister of Health appointed a committee in January, 1921, under the chairmanship of Lord Cave, to consider the financial position of the voluntary hospitals, and to make recommendations as to any action which should be taken to assist them. They reported in May of that year that in the hospitals of London there was a deficiency of £468,413, and in those of the rest of England and Wales of over £280,000; that since 1913 the income of these hospitals had risen by 67 per cent., but that their expenditure (chiefly due to increased cost of provisions, medical requisites, and wages) had increased by 138 per cent. They recommended that to set the hospitals on their legs the Treasury should, as a temporary measure, make a grant of £1,000,000. They stated that they were convinced that the voluntary system is worth saving, and that if it is worth saving any proposal for continuous rate or State aid should be rejected.

They also recommended the setting up of a Central Hospitals Commission under the Ministry of Health with local area committees under it to co-ordinate the work of the hospitals and to distribute any big central funds that might be forthcoming. They suggested various ways in which further funds might be made available, such as voluntary contributory schemes by workmen and employers, and various ways in which economies might be effected.

On the report of this committee the then Minister, Dr. Addison, expressed his agreement as to the importance of maintaining the voluntary system and set up the suggested Hospital Commission and its local committees, but with regard to the grant the Cave Committee had recommended, the Government followed the example of the unjust steward of the parable even to the exact proportion and sat down quickly and voted £500,000 instead of £1,000,000, making it a condition of grant to any hospital that an equal amount of new subscriptions should be found from other sources.

#### *The Labour Party's Hospital Policy.*

The Labour party, through their Advisory Committee on Public Health, have issued a programme of their policy with regard to the hospitals. Their proposals envisage a complete public medical service which shall include hospital treatment. They say, "No public medical service can be efficient that does not provide an adequate number of beds for those requiring institutional treatment, that the accommodation should be very ample." They estimate the present accommodation at 521,194 beds, and in their opinion think there should be 107,906 more. We all know that the present number of beds is insufficient, but such an increase would, in my opinion, be extravagant.

One of their points is that the hospitals are understaffed and that this is the cause of the overcrowding of out-patient departments and the long waiting lists for in-patients, and that the understaffing is due to the monopoly value of the appointments. There is, I think, an element of truth in this contention, but it is more or less inevitable with an unpaid staff.

They say that the one and only salvation for the hospitals of the country is State control and management, but almost in the same breath they testify to the magnificent work which has been done hitherto in the voluntary hospitals, and (as if not having the courage of their opinions of the necessity for State control) they recommend that the voluntary hospitals should be given the option of being taken over by health authorities or receiving grants from public funds conditional on efficiency and representation of the local authorities on the boards, but leaving to the boards complete control.

There is evidently a doubt in the minds of the promulgators of these proposals whether the bulk of the working population would not resent having their voluntary hospitals, which have grown into their affection, and which are in a very real

way under their control at present, taken from them and handed over to an unsympathetic bureaucracy. Perhaps, too, they are not really convinced that State control is the best system.

I hope this question of hospitals will never become a matter of politics. In the general tendency for nationalization of the big public services, I sincerely hope this vital service will be kept outside. It is not a question of popular control. In the hospitals to a large extent we have this already. The beneficiaries are already largely represented on the boards, and will be to a greater extent as the working class come to furnish a larger proportion of the cost. Under the State, the real controllers will be the Chancellor of the Exchequer and the officials of the Ministry of Health, who have little knowledge of local circumstances and scant sympathy with local requirements.

#### *The Medical Profession and the Voluntary System.*

Now as to the opinion of the medical profession, two large representative meetings of the members of the staffs of the hospitals from all over the country were practically unanimously in favour of the voluntary system, and the voice of the general body of the medical profession as represented by the British Medical Association is equally unanimous. This cannot be for any motive of financial gain, for if the hospitals were handed over to the State the members of the staffs would certainly have to be paid. It is because they know that it would be bad for the hospitals, and because they as individuals would lose their freedom of action and thought without which their whole work would be cramped and stultified.

Before concluding I feel that I must say a few words about the relations of the medical profession to the voluntary system. For long years practically the whole of the responsible medical work at the voluntary hospitals has been a free gift by the medical profession to the public, and the demands on the time of the members of the honorary staff have been steadily growing. It may surprise some of you to know that the average number of hours a surgeon on the staff of the Derbyshire Royal Infirmary has to devote to his work there is just about twenty hours a week, apart from any work that he may put in on committees of management. In the twenty years I have been on the staff the surgical work has practically doubled, and it is now work which can, in my opinion, only be undertaken by one who devotes himself specially to surgery. This demand makes a very big hole in one's working week and leaves no very big proportion in which to earn one's living. There are, of course, compensations. In the early stages it gives one the opportunity to learn special work by practical experience, and as one goes on to keep one's hand in. It also gives some advantage in the way of professional prestige and what was referred to in the Labour party programme as monopoly value. But it is a fairly big price to pay for these assets, involving a great amount of physical and mental stress which I doubt if many of us would be willing to give were it not that the work is intensely interesting and performed in the happiest of surroundings, free from petty controls and in an atmosphere of kindly feeling and good fellowship.

The reason why the medical profession is wedded to the voluntary system—although it would probably be better off financially under a State system—is because it knows that under the latter it would be subjected to all the irksome pettiness of bureaucratic officials who, to justify their existence, would be obliged to interfere whether they liked it or no, without benefiting the patient one single jot.

Under the voluntary hospital system as now administered there is not unnaturally a certain amount of feeling among some members of the staff that to some extent their services are being exploited—that a considerable section of the community are getting our services free who are able, and even quite willing, to pay something for those services. There is a dread, too, that with the increasing proportion of the community who get their treatment free the number left may not be sufficient to provide a living for the increasing number of doctors required to do the increased free work. These factors naturally keep consulting fees high and produce a system by which the well-to-do are taxed to pay for those who are not so well off. At a time when the hospitals are struggling for existence it is hard to devise a scheme by which the burden can be more evenly distributed.

The medical staffs have, however, been obliged to lay down that they shall receive a proportion of any funds received by

the hospitals for the treatment undertaken by the hospitals on behalf of public authorities, such as the Ministry of Pensions, the Ministry of Health, and the local health authorities. Further, it has been found necessary to give remuneration for some of the less well paid specialties, such as anaesthetics and x-ray work, in order to obtain the services of suitable men. In the future it may be necessary to extend this principle to some of the junior physicians and surgeons if the right class of men are to be obtained. But this will not, in my opinion, alter the voluntary nature of the bulk of the service which we have so much at heart.

I have not gone in any detail into the ways in which sufficient funds may be got to keep the voluntary system alive. I have contented myself with giving an exposition of the faith that is in me with the hope that it may stimulate public interest in the voluntary system and put off the day when these great institutions are handed over to bureaucratic control.

## PARENTS' PAYMENTS FOR MEDICAL TREATMENT OF SCHOOL CHILDREN.

THE Board of Education has issued to local education authorities a circular (1300 of March 16th, 1923) explaining its requirements in respect of parents' payments for treatment received by their children through the School Medical Service. The imposition of these charges is obligatory under the Education Acts, and "it is not open to a local education authority, in exercising their statutory powers, to adopt arrangements, or to the Board to approve arrangements, which make no provision for obtaining payment or for discriminating between cases in which parents are able or unable to make payment."

The provision contemplated by the Board as meeting the "reasonable requirements of the Act" includes the adoption of an income limit, below which treatment shall be rendered free, and of a scale of charges for the several forms of treatment provided by the authority—both the income limit and the scale to be adjusted in accordance with local conditions. As an example of the arrangements considered satisfactory a scheme is quoted providing for free treatment in the case of a family of two parents and three children where the total weekly income, after deduction of rent, does not exceed 50s. When this income is exceeded, minor ailments may be treated free for the first fortnight, and subsequently at a charge of 1s. for three or 2s. for six months' treatment. Operative treatment of tonsils and adenoids may be offered at 5s. to 7s. 6d., spectacles charged at cost price, and dental treatment at 6d. an attendance, or 1s. for the full treatment. Where wide variety of income exists it is suggested that some corresponding variation should be made in the charges, and it is expressly provided that the income scale adopted in respect of medical treatment should be less severe than that for the provision of free meals, and that investigation into the circumstances of parents should be confined to doubtful cases and as simple as possible. Finally, the Board is prepared to accept, at least for the present, schemes which provide free treatment for minor ailments, subject to the provision of satisfactory arrangements for payment for other types of treatment. In areas where no charge has hitherto been made, and it "is not easy to bring a complete scheme into force at a moment's notice," the Board will accept for the current year any scheme which marks a "reasonable advance" upon previous practice. The circular does not touch upon the vexed question of the definition of minor ailments.

The position indicated by this circular is of considerable interest. The statutory obligation to impose some charge upon all parents able to make any payment dates from 1909, whereas the obligation to provide such treatment, as opposed to the permission to do so, dates only from August 1st, 1919. Apparently what is termed in the circular "the clear intention of Parliament" in connexion with these payments has been to a great extent ignored, both by local and central authorities, over a period of some fourteen years. This being so, we may well inquire what the intention of Parliament really was, why it has been ignored, how far

the present policy is calculated to give it effect, and what will be the probable result of its enforcement.

It is perhaps fair to assume that in providing for payments by parents Parliament had in view one or all of three objects—to restrict treatment to the necessitous, to relieve the pressure on the public purse, and to provide for the case of parents who, unable to meet the full cost of treatment, may wish to contribute towards it according to their capacity. The explanation of the present activity lies, presumably, in the prevailing policy of retrenchment, and in the extension of facilities for treatment to children in secondary schools, many of whom are in more favourable economic circumstances. The experience of a local authority which has endeavoured during the last twelve months to give effect to the policy now laid down by the Board will serve to illustrate both the cause of past neglect of the obligation and the success likely to attend the attempt to make it effective. According to the report of the school medical officer for 1922, the authority, in adopting a scale of charges,

"had in mind two dangers attaching to a rigorous requirement of payment for treatment given: firstly, that such action would serve as a deterrent to obtaining treatment for an ailment in its early stages, and hence would tend to rob the School Medical Service of its main function—the prevention of disease by its early detection and treatment; and secondly, the fact that the sums recovered might not pay for the cost of collection."

The authority calculated that, assuming all parents to be capable of payment on the prescribed scale (a condition which does not, in fact, obtain), the maximum amount recoverable for the year would be about £250, whilst the expense involved in any system of inquiry as to income in individual cases would amount to about £80. Accordingly the adoption of an income scale was rejected in favour of an arrangement by which head teachers inform the school medical officer of all cases in which, in their opinion, the scale payments cannot be met. In all other cases parents receive a request for the amount due under the scale in respect of every child treated. Under this scheme the total amount received by the authority during nine months was £18 4s.

If this experience is typical (and the absence from the reports of school medical officers and those of the Board of Education and its chief medical officer of any indication of the total sum recovered each year in respect of treatment in areas where scales are actually in force is significant in this connexion) it would seem that the present policy is not calculated to meet the first end in view—namely, relief of the rates, with a corresponding decrease in the amount of the Treasury grant. On the other hand, the nature of the charges suggested demonstrates that there is no intention of using them as a means of inducing parents able to obtain necessary treatment privately to do so rather than utilize a service primarily intended for the necessitous. As regards those who may wish to pay according to their means, the object in view might perhaps be more simply attained by a system of voluntary contributions. Moreover, there is a distinct danger that parents actually making the scale payments may imagine that they are paying for the service rendered. It is to guard against this danger that some authorities have adopted an expedient referred to in the Board's circular—namely, the exhibition of a table showing the actual cost to the authority of each service rendered, with a box in which parents may place some contribution towards the difference between that cost and the scale charge. The plan seems rather clumsy, but, provided that in reckoning the cost of each service adequate allowance is made for establishment and administrative charges, it may be of some use.

In view of the difficulty of the whole position it may be asked whether the intention of Parliament in connexion with these payments is, after all, so clear as the Board suggests, and whether the present policy is indeed calculated to give it effect. If the answer to these questions is proved by the experience of the next twelve months to be in the negative, it may be hoped that some amendment of the law will relieve the Board of the thankless task of trying to enforce a policy which would seem not to work well in practice.

SATURDAY, MAY 19TH, 1923.

### IONIC MEDICATION AND THE CONSTANT CURRENT.

THE important place which galvano-therapy holds in modern therapeutics was indicated by the correspondence which followed the appearance in this JOURNAL of a paper by Dr. David Campbell<sup>1</sup> upon ionic medication. His main conclusion was that the amount of any drug introduced in an ionic state into the body by currents which can be used therapeutically is very small. He found that a drug, as soon as it is carried through the skin, is swept away in the blood stream, and produces its specific effect upon the system generally, and that there is therefore no local concentration. Nor is there any evidence of deep penetration; experimental evidence in animals is all against the belief that a drug penetrates farther than the subcutaneous tissue, and it seems quite clear that a similar state of affairs exists in man.

These conclusions, which Dr. Campbell based upon his own experiments and the results of several other workers, have been challenged by some correspondents; but a study of the literature reveals a really overwhelming mass of evidence in their support.

A belief has prevailed that it is possible by means of an electric current to drive drugs down directly into the muscles and joint cavities. The facts known regarding the rate of migration of ions in an electric current render it almost incredible that this can occur under therapeutic conditions, but in addition very careful tests made upon animals by Inchley,<sup>2</sup> and other results quoted by Turrell,<sup>3</sup> show that the ions do not penetrate directly beyond the subcutaneous tissues. How, then, are we to account for the fact that the many practitioners who resort to ionic medication have become convinced of its efficacy?

In the first place we have a very general consensus of opinion that the constant current is of great value in many conditions, and particularly in the relief of pain in such diseases as sciatica, neuritis, and fibrositis. The exact mode of action is unknown, but various possibilities may be mentioned. Dr. Campbell suggests that the action is simply by way of counter-irritation, and the therapeutic application of the constant current does produce irritation beneath the electrodes. This effect can be accounted for partly by the heat produced; the current is most concentrated beneath the electrodes, and the skin has a far higher resistance than any other tissue traversed; hence there is a maximal production of heat beneath the electrodes. Electrolytic effects in the electrodes also are capable of producing irritation, and such action will be most marked when irritant drugs such as salicylates are present; this may account for the superior results stated to be obtained when the electrodes are soaked in salicylates instead of salt solution.

Dr. Turrell, in a recent letter,<sup>4</sup> has suggested that the benefit is due to the heat produced in the tissues

by the passage of the constant current. The objections to this view are that the chief site of heat production must be the skin, and that many observers claim that in many cases the application of the constant current is followed by results superior to those produced by diathermy, although more heat is produced by the latter method. There can, however, be no doubt that heat production plays a very important part in producing the beneficial effects observed. Dr. A. R. Friel has suggested<sup>5</sup> that the important factor is electrical endosmosis, which causes a passage of fluid through the tissues towards the negative electrode. Such an effect can be produced in dead tissues, but it appears doubtful whether it can occur in tissues provided with an efficient circulation. Finally, it is often suggested that the current causes a stream of ions between the two electrodes, and that the cells are stimulated by the passage of these ions through them. The objection to this view is that the surface membranes of cells have a high resistance, so that in all probability nearly the whole of the current passes through the tissue fluids.

Our knowledge as to the action of the constant current is obviously very imperfect, and there is an unpleasant amount of truth in Dr. Turrell's<sup>4</sup> blunt comment: "When we consider that the constant current, the so-called 'ionic medication' or 'ionization,' is commonly ordered by medical men who have no knowledge of electricity or its mode of action, and that the treatment is generally carried out by those who have no knowledge of medicine or the nature of the disease they are treating, it is remarkable that benefit is so often obtained." That such a comment is possible seems to indicate that more regard ought to be paid to teaching electrotherapeutics in medical schools, for there is no doubt that the subject is becoming of increasing importance in practical therapeutics.

Moreover, many of the unsettled problems mentioned above should prove soluble by experiment, and it is to be regretted that more research is not carried out in this interesting and important branch of therapeutics. Dr. Campbell's paper was both interesting and valuable; it is a pity that such papers should have an additional value due to their rarity.

### INHERITANCE OF ACQUIRED CHARACTERS.

For something like a generation the belief that acquired characters are not transmitted to the offspring, reinforced by Weismann's hypothesis of the "continuity of germ plasma," has held sway. Those who ventured to believe otherwise went in danger of condemnation as heretics. Floods of printers' ink were expended in expounding the true doctrine, but most of the writing was *a priori*. For nearly a quarter of a century Dr. Paul Kammerer, a member of the staff of the institute for experimental biology in Vienna, has been working at the subject by experiments of a most laborious character, which seem to have been very carefully made and very cautiously interpreted. Little, however, was heard about them in this country until last summer, when a member of the Cambridge Natural History Society visited Dr. Kammerer, and studied some of the breeding experiments in progress. The visitor was particularly impressed by certain observations on Alytes, and eventually the Society invited Dr. Kammerer to come to this country; the lecture he gave in Cambridge has now been published.<sup>6</sup>

<sup>4</sup> W. J. Turrell: BRITISH MEDICAL JOURNAL, March 24th, 1923.

<sup>5</sup> A. R. Friel: BRITISH MEDICAL JOURNAL, March 17th, 1923.

<sup>6</sup> *Nature*, May 12th, p. 637.

In frogs, which pass the mating period in water, there appears shortly before that time on the inner fingers of the males a dark, rough, horny pad; in *Alytes*, which mates on land, no such pad appears; but if they are induced to mate in the water—by raising the temperature so that if they went ashore they would be dried up—certain changes gradually appear; among these is a pad limited to the inner fingers in the first season, but extending in subsequent breeding seasons to the other fingers, to the ball of the thumb, and even to the under side of the arm. On examining the skin of the thumb of the normal male it was found to be subject to an annual thickening, and it is characteristic of Dr. Kammerer's caution that in view of this natural tendency to pad formation he does not look upon this observation as affording a trustworthy example of the inheritance of acquired character, even though the pad appeared in four successive generations after the original stimulus of warmth was removed.

Setting these observations aside we turn to others which their author thinks may be regarded as crucial. They were made on an Ascidian, *Ciona intestinalis*. It possesses great powers of surviving mutilation and of reproducing parts that have been amputated. It has two tubes or siphons, water being drawn in by one and expelled again by the other. If the two siphons (inhalant and exhalant tubes) be cut off they grow again, and become somewhat longer than they were previously. By repeated amputations individuals were induced to grow very long tubes in which the successive new parts produced a jointed appearance. The offspring of these individuals had siphons longer than usual, but the jointed appearance has been smoothed out. "That is to say, the particular character of the regeneration is not transferred to the progeny, but a locally increased intensity of growth is transferred." Kammerer was able to go further. Weismann's doctrine of the necessary continuity of germ plasma had previously been shown to be subject to exceptions, and a further experiment made by Kammerer is very significant in this connexion. At the hinder end of *Ciona*, in the coils of the intestine, lies the generative organ, a hermaphrodite gland. If the whole of this hinder part of the body be removed, the front part regenerates and reproduces a new generative organ, so that the new germ plasma has been formed from somatic tissue. The long-siphoned Ascidian with regenerated germ plasma gave birth to progeny which were long-siphoned. It has been objected to other experiments that the operation, or the change of environment as the case might be, in some way exercised a direct influence on the germ plasma; in this experiment this objection does not seem to apply. The new long-siphoned individuals are the offspring of an animal with a new generative organ formed after the original operation on the siphons, so that that operation can have exercised no influence on the germ plasma.

Another series of experiments, made on *Salamandra*, yielded some very striking results, though not apparently so conclusive as those with *Ciona*. It is indeed significant that the most convincing result should have been observed in an organism such as *Ciona*, which is low in the scale of living things and may therefore safely be assumed to be the more plastic. Man is so highly specialized, and the same is, indeed, true of all the mammalia, as to be very little plastic. None of the instances of inheritance of acquired characters in man, though very many have been reported at one time or another, can be said to fulfil rigid scientific requirements.

## THE GROUP CLINIC.

LAST week the Westminster and Holborn Division of the British Medical Association held a meeting at the house in Brook Street, W., where a group clinic has recently been established. The occasion has afforded us an opportunity of giving (p. 876) an account of the interesting experiment in the organization of medical practice which is being made by a group of medical men, including consulting physicians and surgeons and specialists with the co-operation of a general practitioner, who is understood to have originated the idea. It is an attempt to introduce the group clinic system, which has existed in the United States of America for some years, with such modifications as conditions of practice in this country may render necessary. The scheme was outlined by Sir Thomas Horder in an address he gave to the Abernethian Society in January, 1922. Briefly it consists in housing under one roof a group of consultants and specialists, and the experts and equipment for pathological and radiographic investigation required in modern diagnosis. When the circumstances permit the scheme to be carried out to the full the patient is examined by such consultants as seem necessary in his individual case, special investigations are made if necessary, and an inclusive fee charged. It is hoped that in this way there will be a saving of time, money, and worry for the patient without any detrimental effect on the income of the experts forming the group. Sir Thomas Horder has answered in advance several of the objections raised against the proposal, but it is possible that in the process of developing the clinic other difficulties will arise. For example, it is proposed to retain a member of the group, "by preference a general practitioner of considerable experience," to indicate the member or members of the group to whom a new patient may best be allocated; it seems a little doubtful whether this plan will work well and really save time. If it is intended that the clinic shall assist the general practitioner in his work, it may be asked whether the best plan would not be to encourage the general practitioner habitually to do what is already permissible—namely, to select the member of the group who shall take initial charge of the patient. If this were done in every case it becomes a question whether the method of "clerking" for the various experts, which seems to be suggested, will prove necessary. Only experience will show; but it seems possible that the expert will find that the reading of notes combined with the questioning of the patient may take almost as much time as if he had himself questioned the patient in the usual way. There can be little doubt that the patient will as a rule be saved time and worry, and probably also money. This seems almost to imply that each expert in a case will receive less than his usual fee for each patient. On the other hand, the member of the group will be saved some worry, perhaps some time, and probably also some overhead expenditure which when working alone he is bound to incur. It seems possible that difficulty may sometimes arise in connexion with treatment, especially of a surgical nature. It is true that the clinic is supposed to be purely diagnostic in character, and that any member of the group is entitled to seek outside opinion. Nevertheless, if one expert in the group should systematically prefer to seek opinion in some special subject outside the group, will he not run the risk of destroying the mutual confidence of the members? Even if he wishes to maintain solidarity, he may meet with difficulties raised by the patient or the practitioner. We ask these questions with no idea of opposition to the principle of the scheme; they may all be solved satisfactorily, and certainly the courage of the promoters of the clinic is worthy of admiration and deserving of success. The only criticism we have heard from a patient is that the congregation of large numbers in the common waiting-room may lead to embarrassment by the accidental meeting of friends.

## AN EPIDEMIOLOGICAL VIEW OF ULTRAVISIBLE VIRUSES.

At a meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine on May 11th, the President, Dr. R. J. Reece, C.B., M.D., in the chair, Sir William Hamer, M.D., read a paper on the ultravisible viruses considered from an epidemiological point of view. He traced the modern history of the subject from Buchner's demonstration in 1897 of an intracellular enzyme in the yeast cell, and observed that the germs of the bacteriologist might perhaps "assume importance in disease mainly by reason of their being able under certain conditions to live in symbiosis with the generally speaking much more deadly though far more minute ultravisible living particles." The important inter-relationships between the ultravisible germs and the bacteria had been compared "to those between man and the tools he works with; or alternatively to the partnership, on a far vaster though probably less important scale, between alga and fungus connoted by the term lichen." Two questions had to be considered: (1) Were germs "hitherto regarded as causal really primarily concerned with fermentations and with diseases, or merely concomitants—that is, associated organisms"? (2) What was the "status, *qua* organization, of the ultramicroscopic 'enzymes'?" In dealing with the first question, Sir William Hamer referred to Lord Lister's classical researches on the souring of milk, and quoted the remark that "it is far from impossible that there may exist ultramicroscopic organisms, as real, as distinct, in structure, and as potent in their effects as is the *Bacterium lactis*." In these words Lord Lister remarkably anticipated the results of later research, and "saw as in a glass darkly the phenomena now familiarly described as those of 'sporting' or 'mutation' in bacteria, and clearly discerned that ultravisible particles might play a part in these." With regard to the second question, the opinion was expressed that the experimental results suggest that each germ must be assigned a very complex constitution *qua* enzymes; one enzyme might be represented by numerous particles in a condition of great activity and apt for rapid multiplication; another might be poorly represented by particles in an inactive or dormant condition. After outlining the present state of opinion respecting the physico-chemical status of catalysts and enzymes, Sir William Hamer remarked that "it would simplify things a great deal if, taking our courage in both hands, we boldly declared that many 'organic catalysts' are really living organisms." He referred with approval to the late Professor Minchin's speculations regarding the simplest forms of life and their origin, and added that "an outstanding difficulty of the epidemiologist, confronted with all the later developments of the germ theory, is, however, that of explaining persistency of type in epidemic disease—persistency such as that displayed, say, by measles or small-pox... In the case of ultravisible germs of epidemic disease, it may be that, while variability of type is favoured by association of the primary ultravisible organism with various satellite secondary invaders, there is an inevitable return, at appropriate intervals, to phases of influence which again and again repeat themselves. Just as syngamy prevents a species from breaking up into strains, so some equilibration between a primary influence and secondary influences encountered in the bodies of the hosts may bring about major waves of epidemic disease." De Vries, he went on to point out, had hinted at something of this kind in his "periodic mutations" of the higher plants, and said that "analogous phenomena will at once suggest themselves to all those who have followed up Creighton's teaching with regard to influenza, scarlet fever, and diphtheria. Minchin's ultramicroscopic chromatin grains may then become endowed by mutation with the capacity for exercising marvellous powers; for

while an evening primrose, when it mutates, causes comparatively speaking but little disturbance in the world at large, the ultravisible germ of influenza, on the other hand, when it manifests its greatest effects, the pawn becoming, so to speak, a queen, determines development of influenza in pandemic phase, 'posting' abroad and wreaking terrible havoc among the peoples of the globe."

## LIFE AND PROBLEMS IN A MEDICAL UTOPIA.

THE conditions of life in a medical utopia were reviewed by Dr. J. Walter Carr in an entertaining address delivered to the Medical Society of London on May 14th. Those privileged to live under the despotism of some benevolent autocracy, such as a super-ministry of health, will, in the days of a medical utopia, lead a strictly hygienic existence under the watchful supervision of the State from infancy to old age. The young couple about to get married will be provided with certificates of fitness and receive instruction in sex hygiene; pregnancy will be notifiable to the medical officer of health, and the unborn child will be brought into the grip of the municipal authorities even before parturition, which, of course, will not be tolerated in the unhygienic surroundings of the home. Compulsory attendance of mother and child at the infant welfare centre will enable the State to regulate the life of the newborn child until he attains school age, when he will be transferred to the care of the school medical officer, who will in due course hand him on to the panel practitioner when the child ceases school attendance. Soon after birth the question will have to be faced as to which superfluous organs it will be necessary to remove for reasons of personal hygiene and the prevention of future disease. Boys will, of course, all be circumcised, but in all probability the appendix also will be removed as a matter of routine in all new arrivals in the medical utopia. The complete removal of the colon as soon as possible after birth would prevent the onset of intestinal stasis and the innumerable grave, distressing, and common diseases attributable to absorption of toxins from this organ. The colon is a veritable cesspool; its removal is essential to health, and in a medical utopia a race of surgeons would be evolved capable of performing the operation of colectomy with great dexterity and without danger to the patient. For the benefit of conscientious objectors (if such there be) paraffin would be distributed gratuitously by the medical officer of health. Tonsils and adenoids would be compulsorily excised in a well regulated State, and there is much to be said for the removal of teeth of the second dentition immediately or soon after their appearance, instead of removing them one by one after pyorrhoea and decay have inevitably supervened. In women the uterus and mammary glands will be excised after the climacteric in order to avoid malignant disease, and in man at the corresponding period of life the prostate will be removed, any deficiencies in internal secretion being made good by organotherapy. Vaccination against small-pox will be carried out every ten years and a well devised blend of half a dozen organisms will be used for compulsory inoculation against diseases of the respiratory tract, such inoculation being carried out every few months throughout life. Meanwhile, the mind will not be neglected, for the psycho-analysts and interpreters of dreams, who will be attached to all infant welfare centres, schools, and courts of justice will watch over the developing intelligence and by timely intervention nip in the bud those undesirable complexes which, if allowed to develop, would lead to such preventable mental afflictions as neurasthenia, psychasthenia, and melancholy dispositions. Guarded and controlled in this salutary fashion, man will ultimately pass into a condition of simple senile decay, but there will probably be special provision for old people, homes where they can pass their declining days in attractive surroundings equipped with a lethal chamber, under strict medical control,

by means of which the aged may pass out peacefully from the kindly supervision of the authorities of the medical utopia. Will the inhabitants of the medical utopia be better off than the citizens of to-day? Dr. Carr was forced to the conclusion that he would rather see England free than England thoroughly healthy. Despots always abuse their power, and however high-minded may be the conceptions a man desires for his fellows they may none the less be completely erroneous. Health depends on obedience to laws, but these laws must be intelligently understood and should be voluntarily obeyed. Social conditions must be improved in the future, but the individual must also be educated to a social consciousness, and a happy blending of socialism and individualism offers a prospect of true evolution. Obedience to the moral law is the only way to a medical utopia.

#### THE LISTER INSTITUTE.

THE annual report for last year, presented by the governing body to the meeting of members of the Lister Institute on May 16th, is a record of a very large amount of valuable research work done under the inspiration of the director, Professor C. J. Martin, C.M.G., F.R.S., and also of much important routine work conducted in the department for the preparation and study of antitoxic serums at Elstree, and the department for the preparation and study of antivariolous vaccine at Hayle. In the department last mentioned a series of experiments, continuing those conducted in the previous year, has demonstrated that while minor differences in the immunization value of a stock lymph against different strains of African variola exist, a high degree of immunity is conveyed against all those experimentally tested. The experiments lend no support to the view put forward by some medical officers of the Colonial Service that the variola of native West Africans is not the same as the variola of Europe. In the department of bacteriology Dr. M. Cowan has continued her work on strains of streptococci. Mice immunized with the non-virulent (R) type are found to acquire a certain degree of immunity against the virulent (S) type. The results have an obvious bearing on serum therapy in streptococcal infections, and horses are being immunized at Elstree with both types, in order to ascertain whether the resultant serums differ in their protective action. When frequently subcultured both strains remain stable, but in freshly isolated growths left for long periods without subculture the non-virulent type tends to become dominant. Miss D. Steabben, a Jenner memorial research scholar of the Institute, had begun a research into the effect of various organic and inorganic colloids, in the hope of elucidating the physiological basis of so-called "shock" therapy and non-specific vaccine therapy, when her services were requisitioned for the National Collection of Type Cultures owing to the absence of the staff through illness, due to the newly discovered Californian disease, tularaemia. A culture of *B. tularensis*, the causative organism, had been received from the Government Health Laboratories, Washington, in the spring of 1922, and passage through guinea-pigs and mice was readily effected. In July Miss Rhodes, the assistant curator, fell ill, and in September Dr. R. St. John Brooks, the curator, and also Dr. Schütze. It became necessary to elaborate a method of serological diagnosis; a suitable antigen was not then available, but from the organs of infected mice, which teem with *B. tularensis*, suspensions of the organism were prepared by a special process, and by their aid a diagnosis was established. Dr. Schütze made a rapid recovery, but the infection in the other two members of the staff ran a tedious, chronic course. Both returned to light work in January, but Miss Rhodes contracted what appeared to be a genuine recrudescence of infection shortly after resuming work, and had to be invalided again. A great part of the time of the staff of the department of experimental

pathology and assistants working in it was taken up by investigations into questions relating to nutrition and vitamins, with special relation to rickets. Many important and some unexpected results were obtained. To this part of the report we hope to recur at an early date. The governing body, in concluding its report, expresses its satisfaction at the high quality of the work carried out at the institute during the year and the importance of the results obtained, and places on record its appreciation of the devoted and enthusiastic labours of the director and of the scientific staff in the furtherance of the objects for which the Lister Institute was founded.

#### STERILIZATION OF MENTAL DEFECTIVES.

"Thou did'st prevent me; I had peopled else  
This isle with Calibans."

DURING a large part of the second half of last year our correspondence columns bore witness to the interest taken by readers in the vexed question of what is to be done with the mentally unfit. The correspondence on sterilization was initiated by Lieut.-Colonel A. E. J. Lister on July 1st, and was continued by many other readers (among them Sir Archdall Reid and Sir Bryan Donkin) from many points of view—biological, sociological, and administrative. When the debate seemed to be at its height Sir Bryan Donkin laid down the proposition that without a clear understanding of certain key words—inheritance, reproduction, innate, acquired, germinal, somatic, and the like—no useful purpose could be served by discussing the question of sterilization of the feeble-minded. This plea for precision in the use of biological terms seemed to have some effect; at any rate, the correspondence thereupon died down. Interest in the subject has, however, been maintained, as is evidenced by the discussion at the annual meeting of the Westminster and Holborn Division (*BRITISH MEDICAL JOURNAL*, May 5th, pp. 754, 760). The subject was introduced by Dr. Gibbons, whose paper, which was published in full, has provoked some further correspondence, which, however, does not seem likely to add much to our information, beyond the fact that some of the laws passed by State legislatures in America are not enforced. By a coincidence we have received quite recently from New Zealand a communication on this matter by Dr. Clennell Fenwick, C.M.G., consulting surgeon to the Christchurch Hospital. He sends us extracts from the local newspaper showing the interest taken by certain hospital authorities in the problems of mental degeneracy. In New Zealand the hospitals are managed by hospital boards, elected by the ratepayers. Not the least active of these is the North Canterbury Hospital Board, which has lately shown its concern for the public welfare by referring to its hospital committee, whose chairman is Dr. Fenwick, the question of the sterilization of mental degenerates and epileptics. The committee passed a series of recommendations, and these were adopted by the board. Apart from the merits or defects of the recommendations, their formal adoption has this advantage, that it implies subsequent consideration of the whole question by the Government of New Zealand. In further proof of the attention now being devoted to this problem by the medical profession at home and abroad, we may note that the Section of Medical Sociology at the forthcoming Annual Meeting of the British Medical Association at Portsmouth has chosen the topic of mental deficiency in its various aspects as the principal dish in its bill of fare.

#### MEDICAL WOMEN'S FEDERATION.

THE annual meeting of the Medical Women's Federation this year was celebrated by a dinner held at the Trocadero Restaurant, London, on May 10th. Lady Barrett, C.B.E., M.D., presided, and over 200 members and friends were

present. The official guests included the Earl of Onslow, Captain Elliot, M.P., Sir George Berry, M.P., Sir William Hale-White, Sir Sydney Russell-Wells, M.P., Mrs. Swynnerton, A.R.A., Mr. H. J. Waring, Mrs. Wintringham, M.P., Dr. Alfred Cox, O.B.E., Medical Secretary of the British Medical Association, and Dr. James Neal, General Secretary of the Medical Defence Union. After the loyal toast had been honoured, Lady Barrett gave a brief account of the origin and progress of the Medical Women's Federation. She said that it was only six years since the scattered associations of medical women in Britain were united into one federated body, largely as the result of the efforts and enthusiasm of Dr. Jane Walker. The membership then was 355; now it was 800. The fellowship and helpfulness engendered proved a powerful stimulus. It seemed to be a case of rejuvenescence by conjugation. In the last year, although the subscription had been increased, the membership had increased by over 100. In the first quarter of this year 93 new members had been enrolled. Great interest was being shown by the newly qualified medical women, and in many places hospital students were becoming student associates. This movement, like so many other good things, had originated in the provinces, and on the initiative of the students themselves. Already over 400 students had become associates. The medical women of Britain were also seeking to join hands with the medical women of other countries. The constitution of the International Medical Women's Federation, which was drawn up last year at Geneva, had been approved by the medical women of eighteen countries. They hoped that this international association would do much in the promotion of international friendship and peace. At this, the first dinner of the Federation, they were naturally anxious to entertain as guests their men colleagues in the profession. Medical women were in no way antagonistic to medical men, but desired real co-operation. Sex antagonism within the profession was a bogey. Great contributions had been made to progress by medical men in the past, and they hoped that even greater contributions might be made in the future by men and women working together. The toast list included "The Medical Profession," proposed by the Earl of Onslow; "The Medical Women's Federation," proposed by Sir Sydney Russell-Wells, M.P.; and "The Guests," proposed by Dr. Jane Walker in a humorous and vigorous speech, in which she paid a graceful tribute to the friendly help medical women had always received from their men colleagues. The occasion was a great success in every way.

#### ATMOSPHERIC POLLUTION AND FOG PREVENTION.

The question of the extent to which fog in London is caused by atmospheric pollution due to preventable causes was the subject of a report by the Public Control Committee to the London County Council on May 15th. The report describes fog in London as being caused chiefly by the smoke arising from domestic chimneys, industrial operations, railway and road locomotives, and steam vessels on the Thames and its subsidiary waters. On account of the extent of the drained area and the artificial warmth of the city there is reason to believe that if the smoke conditions of London and of the populous surrounding area, especially to the east, were mitigated, conditions favourable to the formation of fog would not arise so readily in London as elsewhere. During the last twenty years there has been a great development in the use of gas and electricity for heating purposes. The three gas companies which supply London had only about 600,000 appliances in use for cooking and heating twenty years ago; now they have more than two millions. The number of millions of units of electricity sold annually for all purposes in London twenty years ago was 66, now it is 450, and this increase is almost entirely due to the extended use of electricity for heating and power, because, although

the use of electricity for lighting purposes has increased, the efficiency of the electric lamp has increased also, and the amount of current consumed in lighting is thought not to be appreciably greater. The Committee repeats the conclusion reached by many predecessors when it expresses the opinion that the domestic chimney is responsible for a large proportion of the London fog. Nearly five million tons of coal are consumed annually in London for domestic purposes. The remedy suggested is that steps should be taken to induce builders to fix types of grates which will be effective for warming and yet in large measure smokeless when burning bituminous coal, and so constructed that gas appliances can readily be fitted to them. The Committee agrees also with the opinion so often expressed in the past that the use of the old-fashioned kitchener should cease. In industrial and railway operations, plant and boilers can be so constructed and worked as to produce very little visible smoke. When an engineer is careful about the calorific value of the coal supplied to him, the conditions of his furnaces, and the methods of his stokers, he not only does not offend in the matter of smoke emission, but he works with an economy of coal consumption not otherwise obtainable. Certain observations have been made at lofty points in various parts of London, and during five periods of two hours each the total number of black smoke nuisances observed was 1,288, and of smoke not black 1,178. Serious smoke nuisance occurs at the Royal Arsenal and Dockyard, Woolwich, which is exempt from the provisions of the Public Health Acts, with the exception of nuisances from rail and road locomotives, the dilatory machinery of the Public Health Acts has to be employed in dealing with offences. The Committee considers that if the smoke nuisance is to be effectually prevented progressive penalties must be provided for offences. It suggests certain lines along which local authorities might co-operate with manufacturers and others, and generally endorses the broad and comprehensive proposals of the Departmental Committee on Smoke and Noxious Vapours Abatement. The report agrees that the problem has now become so acute that a well-thought-out and properly co-ordinated solution is manifestly called for, and that the existing law on the subject is chaotic and largely ineffective and requires codification. Local authorities are ill equipped with the necessary powers for enforcing compliance with the statutes, and there exists at present no encouragement to manufacturers and others to diminish the large volumes of smoke poured into the atmosphere. The Government is asked to introduce at an early date legislation on the lines indicated in the report of the Departmental Committee.

#### THE SURREY AND CROYDON VOLUNTARY HOSPITALS COMMITTEE.

In an admirably brief document the Surrey and Croydon Voluntary Hospitals Committee has issued its report for the year 1922. After tracing the origin of the Committee to the recommendations of the Cave Report, and describing its constitution with Lord Cave himself as chairman, the report comments on the memorandum on the hospital accommodation available in voluntary hospitals of the Surrey area, drawn up by Dr. Cates at the request of the Committee. Dr. Cates, who is County Medical Officer of Health, arrived at certain conclusions which were adopted by the committee; one was that from the public health point of view the number of beds in voluntary hospitals in Surrey is insufficient, especially in the accommodation for women and children and for some special diseases; another was that piecemeal extension of small buildings not originally planned as hospitals is uneconomical and to be deprecated; and a third that medical work should be gradually concentrated in larger and better equipped institutions. General hospitals of this type are, it was considered, required in the Guildford, Redhill or Reigate, and perhaps Surbiton or Epsom areas. One of

the first steps taken by the committee was to ask all voluntary hospitals in the area to furnish their last annual report and statement of accounts, together with particulars as to the areas they serve; the request was accompanied by full information of the object and functions of the County Committee. It appeared that only nine out of thirty-two hospitals had applied for grants, and in the end it was only found necessary or possible to approve grants for four hospitals. The Surrey and Croydon Committee made suggestions to the trustees of the late Mr. Leopold Salomons with regard to the distribution of £5,000 among the hospitals of Surrey; it gave advice, at the request of the Earl of Onslow, with regard to a scheme for the extension of the Royal Surrey County Hospital at Guildford; it endeavoured to assist in a scheme for the rebuilding of the Reigate and Redhill Hospital, which came to naught owing to financial considerations; and it is pressing upon the hospitals in its area the importance of adopting a uniform system of accounts. After considering the matter of conflicting appeals for the maintenance of voluntary hospitals, the committee expressed the opinion that a Central Fund for provincial hospitals, formed on the lines of King Edward's Hospital Fund for London, would assist in the development of country hospitals on approved lines. In conclusion, the report states that the work of the committee as local advisers of the Hospitals Commission is likely to be continued throughout the current year, in respect of applications for grants towards the reduction of accumulated deficits; that it is proposed to make inquiries as to the best method of organizing systematic contributions from employers and employees; and that the question of co-operation in hospital administration and the purchase of stores is under examination. The expenses of the committee, which were very moderate, were met out of grants from the Surrey County Council and the Croydon Borough Council. The report seems to show that the Surrey and Croydon Voluntary Hospitals Committee is dealing very tactfully with a difficult problem. If other committees throughout the country are proceeding on the same lines there can be little doubt about the benefits which will accrue to the voluntary hospital system. It seems desirable that time should be given for the development of these committees on advisory lines before any attempt is made to confer upon them definite powers with regard to the co-ordination of hospitals throughout their areas. It would appear that the Surrey and Croydon Committee aims at the ideals of King Edward's Hospital Fund for London, and proposes to devote its energies to development on the lines of that excellent body.

#### SMALL-POX PREVALENCE.

In the four weeks ending April 28th, 134 cases of small-pox were notified outside of London. In the successive weeks the numbers were 32, 51, 20, and 31. The counties affected were Derby with 39 cases, Gloucester 25, Lancaster 22, Nottingham 19, the West Riding of Yorkshire 17, the North Riding 5, Durham 4, and Monmouth, East Surrey, and Wiltshire 1 each. In Derbyshire, Clowne and Heanor had 17 cases each; in Gloucestershire, Cheltenham had 18 cases; in Lancashire, Nelson had 21 cases; in Nottinghamshire, Basford had 11 cases, and Stapleford 7. In the West Riding Doncaster had 10 cases, and Sheffield 2, and in the North Riding Middlesbrough had 5 cases. From the beginning of the year to April 28th the notifications numbered 652. The average for the first thirteen weeks was 40; for the four weeks of April it was 34. In reporting on the position in our issue of April 14th (p. 643) it was noted that at Clowne a prominent anti-vaccinationist had been summoned to the police court for failing to notify a case in his house, but was unable to obey the summons because in the interval he himself had been attacked by the disease and removed to hospital. The story is continued in the *Sheffield Independent*

of May 1st. The clerk to the District Council of Clowne applied to the magistrates for permission to withdraw the summons, explaining that though the man was formerly opposed to vaccination he had now changed his views on the matter. The magistrates refused the application and decided that the case must go on, but allowed a month's adjournment, presumably because the converted anti-vaccinationist was still in hospital. The chairman of the magistrates made some pointed comments on the District Council's attitude in the outbreak. He said that he understood one woman who was told she had small-pox was told also to stop in the house for a few minutes until the ambulance came, but when it arrived it had to wait for three-quarters of an hour because the woman had gone out shopping! It may be mentioned that the Registrar-General's weekly returns show no fewer than 84 notifications of small-pox in Clowne from the beginning of the year to the end of April.

#### THE ROYAL SOCIETY'S CONVERSAZIONE.

THE first of the conversazioni, which it is the custom of the Royal Society to give every year, was held on Wednesday evening in the Society's rooms at Burlington House. The National Institute of Medical Research had a number of interesting exhibits. One of these, shown by Dr. E. H. J. Schuster, was a new recording katha-thermometer, in which the heating was carried out automatically by electricity after each cooling period, and the length of each such cooling period was automatically recorded on a roll of paper. Another exhibit from the same laboratory was that of Dr. Leonard Hill and Dr. Eidinow illustrating the lethal power of ultra-violet rays as manifested by granulation and loss of mobility in hay infusoria after exposure to the rays. A third exhibit from the National Institute embodied improvements made by Mr. J. E. Barnard and others in the method of dark-ground illumination for microscopical purposes; it was shown that a progressive increase of efficiency could be obtained by using illuminators of high numerical aperture, together with objectives corresponding thereto. Dr. Hele-Shaw, F.R.S., had on view a special laboratory filter of a simple and inexpensive type, which he called a stream-line filter, from the fact that the fluid which had to be filtered was caused to flow with a stream-line motion. The results of certain researches on the markings on the scales of herring as a means of estimating the growth of the fish were also shown, as well as some photomicrographs of certain woods which had a peculiarly low thermal conductivity, and, from the Rothamsted Experimental Station, an illustration of the importance of the flocculation of soils. The Department of Zoology of the British Museum contributed a number of interesting African exhibits, including the contents of the stomach of a man-eating crocodile, and the modification of dentition of some African vertebrates. Another exhibitor, Mr. E. Hatschek, has succeeded in imitating organic forms by drops and vortices of gelatin. The gelatin was run into suitable coagulating solutions with the temperatures and densities so adjusted that the gelatin set to certain desired forms, and then, owing to shrinkage, a number of features like radial ribs, undulating membranes, coronated discs, and so forth, made their appearance; he had even succeeded in obtaining models astonishingly like red blood corpuscles. The research work of the Institute of Industrial Psychology was illustrated by charts showing how a study of the miner's movements in wielding the pick at the coal surface had effected an increase of about 16 per cent. in output, with lessened exertion for the miner. Another matter which appeared to be shown conclusively was that frosting the miner's standard lamp resulted in a striking reduction in the number and duration of the disturbing after-images, thus bearing out the claim of the

miners themselves that the frosted image afforded them better vision and caused less eyestrain. Another chart, which had to do with a different class of workers, showed the improvement in the work curve by introducing twice daily a fifteen minutes' period of change of work, or by encouraging rhythmical movements and reducing needless decisions. The exhibits included some examples of ancient as well as modern science. Among these were Egyptian water-clocks and some surveying instruments of the ancient Romans. The Jenner centenary found a reflection in the exhibition of the certificate of the candidature of Dr. Edward Jenner for the Fellowship of the Royal Society, a distinction he obtained in 1789.

#### RIVERS MEMORIAL FUND.

No one will question that the services of the late Dr. W. H. R. Rivers to the sciences in which he was particularly interested—first those of anthropology and ethnology, and later psychology—were so great as to deserve some permanent memorial. We are glad, therefore, to hear that a committee has been formed to give practical effect to a desire which has been expressed in many quarters. The committee includes Sir Charles Sherrington, President of the Royal Society, Sir Humphry Rolleston, President of the Royal College of Physicians, Sir James Frazer, Dr. Henry Head, Professor Elliot Smith, and Dr. C. S. Myers. The treasurer is Dr. L. E. Shore, St. John's College, Cambridge, to whom contributions may be sent. It is intended that the proceeds of the fund shall be devoted to the promotion of those sciences in which Dr. Rivers took a special interest, but until the amount and the wishes of the contributors are known no definite decision will be reached.

#### EXCHANGE PROFESSORS.

IN the article under this heading published last week (p. 827) describing the visit of Sir Harold Stiles to Boston, the first paragraph was unfortunately so expressed as to produce the impression that this was the first occasion on which such an exchange had taken place between this country and America. It ought to have been stated that Professor Gask, director of the surgical unit of St. Bartholomew's Hospital, went to Boston to replace Professor Cushing in the same way last year, and that in June, 1922, Professor Cushing reciprocated by occupying the chair at St. Bartholomew's Hospital for a similar period.

THE Ontario Legislature has established a research chair for Dr. Banting, the originator of the idea that diabetes might be controlled by extracts of the islands of Langerhans, for which the name "insulin" had been suggested by Sir Edward Schafer a good many years ago, and under which it has now become a commercial product. The success which attended the inquiry instituted by Drs. Banting and Best in Professor Macleod's laboratory in the University of Toronto is now well known. The income of the chair, to which Dr. Best will act as assistant, will be 10,000 dollars a year. Dr. Banting intends to be present at the discussion on diabetes in the Section of Medicine at the Annual Meeting of the British Medical Association in Portsmouth.

THE next session of the General Medical Council will begin on Tuesday, May 29th, at 2 p.m., when the President, Sir Donald MacAlister, will give an address on the work of the Council since the November session, and penal and other matters will be considered. Dr. W. L. H. Duckworth, Reader in Human Anatomy in the University of Cambridge, has been elected the representative of the University on the Council, in succession to Professor Hopkins, who did not desire reappointment.

## MEDICAL SOCIETY OF LONDON.

### 150TH ANNIVERSARY DINNER.

THE 150th anniversary dinner of the Medical Society of London took place at the Hyde Park Hotel on May 15th. LORD DAWSON OF PENN presided, and the principal guest was H.R.H. The Prince of Wales. About 350 sat down at the tables, and the company included:

Viscount Astor, the Bishop of Birmingham, Dr. R. A. Bolam, Sir Anthony Bowlby, Lord Burnham, Sir Archibald Garrod, Viscount Gladstone, Sir William Hale-White, Dr. G. E. Haslip, Sir Thomas Horder, Sir Robert Jones, Viscount Knutsford, Major-General Sir William Leishman, Sir William Macewen, Sir George Newman, Lord Riddell, Sir Charles Sherrington, and Mr. H. J. Waring, Vice-Chancellor of the University of London.

LORD DAWSON, in proposing the health of the principal guest, said that in addition to the representatives of medicine there were many representatives of allied professions, with varied interests and gifts, but hosts and guests alike were one in loyalty and support for their beloved Prince. In his interest in medicine the Prince was following the tradition of his great ancestors. To kings in ancient times were ascribed powers of miraculous healing. In those old days who would not have preferred the "royal touch" to the rigours of medical treatment? Imagine fourteen doctors around the bedside of Charles II! But that "royal touch" still existed. It was a human touch. It was at the service alike of the individual and of the body politic. It was prompted not by favour, but by need. It owed its success not to miracle, but to high endeavour, unflinching kindness, and a feeling for human frailty.

#### THE PRINCE OF WALES'S TRIBUTE TO THE GENERAL PRACTITIONER.

THE PRINCE OF WALES said that it was a common boast among members of the medical profession that they practised the oldest science known to man. He could not imagine a time when doctors had not been needed. The only reason why they were not mentioned in the record of the Garden of Eden was evidently because Eve knew the prescription, "An apple a day keeps the doctor away." (Laughter.) That evening he was a solitary and nervous patient surrounded by many of the keenest practitioners in London—an island in a sea of medicine. But as one who had had long experience of the characteristic kindness of the profession, he would be ungenerous if he did not feel himself at home. Anybody who was as familiar with hospitals as himself could not have failed to observe that the art of healing had a particularly good effect on those who practised it. He went on to pay the general practitioner a special tribute. The general practitioner was a devoted and, he was afraid, sometimes an unrecognized friend of the community. Upon him in the long run the health and well-being of the community depended. Everyone outside the profession owed the general practitioner gratitude. In referring to the presence of three distinguished physicians from the United States, His Royal Highness remarked that America was "a country to which we owe a great deal," but when the laughter had subsided he said that he was referring to medicine, not to money. One aspect of the Society's history appealed to him particularly—namely, the close connexion between the Society and the national hospital system. The Society's foundation showed that medicine at that time, in 1773, was passing from the twilight of quackery into the clear light of science. The progress during those 150 years had proceeded on parallel lines with the growth of the modern hospital system. The hospitals were at once the school and the workshop of medical science—centres to which the doctor could go to get further knowledge, and the suffering to get the practical application of that knowledge. Without the hospitals medical science would be a comparatively barren thing. The Society had grown up alongside the hospital system; many of the great London hospitals dated from about the same period, and to that hospital system the Society had been a very loyal and helpful friend.

## MR. LLOYD GEORGE ON MEDICAL ACHIEVEMENT.

MR. LLOYD GEORGE gave the toast of "Medicine and the Medical Society of London," coupling with it the name of Lord Dawson. During the 150 years of the Society's existence medicine had, he said, seen great changes. It was only about forty years before the foundation of the Society that the Barbers and the Surgeons separated—a very good indication of the state of medical science at that period. The science of destroying human life had been perfected from generation to generation, but until after this Society was founded the art of saving life had hardly moved. Science had been called in to serve the purposes of destruction; but when it came to the saving of life it had been regarded too often as an intruder. Since that time, however, there had been almost incredible changes—changes which were like a romance. This later age had been the age of unlocking. It had been the age of revolution—political, industrial, scientific—and there was no profession which responded to the revolutionary spirit more readily than medicine. There was a time when the human body was like a land which was the prey of bandits—bandits roving, sulking in recesses, issuing forth to pillage and slay with impunity. The strong might resist, the weak invariably fell. Even the most expert professors of medical science had not known who these bandits were nor what measures to take to deal with them. But at length the whole dark continent of disease had been explored. These bandits had been discovered, docketed, identified, blacklisted, tracked to their lairs, and in the majority of cases exterminated for the benefit of mankind. Medical science had given human life a better fighting chance—had turned the odds in its favour for as long as the "military age" (in the medical sense) might last. These were achievements over which they had a right to rejoice. The Prince had spoken of the hospitals. Mr. Lloyd George recalled the fact that during the illness of that former Prince of Wales who afterwards became Edward VII, Sir William Gull said to the royal patient, "Sir, you are as well cared for as if you had been in a hospital." In speaking at Manchester the other evening he had occasion to remind some of his fellow citizens that when they had a good doctor they ought to be grateful to the hospitals for the training he had received, and when they had a bad doctor they ought to thank the hospitals that he was no worse! But the greatest advances in medicine were in the preventive direction. Recent history taught that it was a dangerous and costly enterprise to expel an invader once he had a grip upon the soil, and even if he was expelled he left behind a devastated area which took years to recover. But preventive medicine had put up barriers against attack. There was a good deal in the old Chinese idea of paying the doctor for as long as one was well. It was a bit of profound philosophy from a reflective race. In sanitation, water supply, food, the teaching and inculcation of habit, and above all in the housing of the people, science had exerted itself nobly for preventive ends. It was a great saying of a very great statesman fifty years ago, that the first consideration of a Minister should be the health of the people. All would remember Disraeli's famous speech in which he framed the saying *Sanitas sanitatum, omnia sanitas*. They had a right, on looking back at the triumphs of their art, as they beheld the legions of disease driven from the field, to meet in banquet and rejoice over the past, and toast the future prosperity of medicine and of the Medical Society.

LORD DAWSON acknowledged with gratitude the eloquent and impressive tribute from one so distinguished in achievement as Mr. Lloyd George. The Medical Society of London, before the end of the eighteenth century, had come to occupy a distinguished position in the world of medicine, but a study of its proceedings in that early time showed that its members were for the most part concerned with phenomena and failed to get down to causes. It had to be remembered that Darwin, Lister, Pasteur, and Koch had still to live. The watchwords of the new medicine for which the Medical Society of London stood were discovery, humanism, and statesmanship. In speaking of discovery he made a reference to the investigations which had resulted in the production of insulin. That remarkable and important achievement was the outcome of proper co-ordination between laboratory and ward. Insulin, he went on to say, had been put before the

world with a restraint wholly admirable, and there was every likelihood that its ultimate value would be more and not less than appeared from the original statement. He touched also on the investigation of the scourge of cancer, and in doing so said that far too little homage was paid to those who attained only negative results. Such results were part of the pathway to truth. Medicine was a wide and open field in which all who could contribute anything were welcome, subject to the condition that only those who had had an ordained training could be accepted to take the full responsibility of the treatment of the sick. As a distinguished Frenchman had said, there were no illnesses, there were only sick people. In the practice of medicine the qualities of insight, understanding, and judgement were necessary. Uniformity was not desired, yet it was sometimes difficult to convince even well-trained minds outside the profession that medicine had no panacea, no short cut, no talisman to offer, no magic beyond that which belonged to understanding and kindness. Medicine also required statesmanship if its benefits were to be of the best use to mankind; health as a positive conception must more and more claim attention, and, in closing, he praised the public health service, which was unsurpassed by that of any other nation.

## SISTER PROFESSIONS.

SIR JOHN BLAND-SUTTON, in proposing the toast of "The Sister Professions and the Guests," said that the need for professional assistance, in one form or another, belonged to the human being from the moment of his birth right to the administration of his estate after death. Medicine had its evident associations with the law; he fancied, by the way, that if some medical theories were tried by judge and jury, on the lines of law court procedure, they would not survive. Medicine had associations also with the Church, and his advice to all men newly starting in practice was to stand well with the vicar! The painter or sculptor and the doctor had this in common, that they both must have some knowledge of human anatomy and of psychology. There seemed to be considerable sympathy between art and medicine, to judge from the number of medical portraits exhibited year by year in the Academy; one which gave him great pleasure this year was that of Miss Aldrich-Blake, and the mention of her name reminded him that the Medical Society, though a progressive society, still barred its doors against women. Some medical portraits in the Academy owed their origin, no doubt, to the vanity of the sitters; others were due to the reverence of pupils for great teachers, and yet others, best of all, were tributes of affection from the artist to the doctor for service rendered.

The Lord Chief Justice (LORD HEWART), in responding to the toast, claimed for the sister professions that they were all more or less associated with the great art of healing. That was certainly true of the Church; it was true also of literature, and he believed it was no less true of the profession of the law. The business of the lawyer was not, as was ignorantly supposed, to provoke and prolong litigation, but, on the contrary, it was extraordinarily like the business of the physician, to reconcile difficulties, to heal or prevent contention, and to make the wheels of the body politic move as smoothly as possible.

MR. NEVILLE CHAMBERLAIN, who also responded, said that he thought it necessary to state that he was now Minister of Health, because, to judge from his correspondence, a good many people still regarded him as Paymaster-General! As one who began his public work on the board of a general hospital, and who, throughout his municipal career had served on a public health committee, he was not likely to lose sight of the medical side of the work of his new office. He desired to do something towards bringing the great advances in medicine and surgery within reach of all, rich or poor, and of those who were neither rich nor poor, and whose lot in this respect was perhaps the most unfortunate of all. Though it did not seem that disease would ever be conquered, for the medical profession invented new ailments as fast as it learned to cure old ones, yet he thought they were justified in hoping that, like those mathematical problems which worked out to infinity, while they never actually achieved their end, they would advance continually towards it.

## A CORONER'S ATTACK ON THE PANEL SYSTEM.

SOME remarks made by Dr. Edwin Smith, coroner for North-East London, at the conclusion of an inquest on May 11th constituted an attack on the panel system. It was a sweeping, indiscriminating onslaught, based on evidence which would not survive any serious attempt at investigation. For instance, he made the wholly unsupported assertion that there was widespread and increasing dissatisfaction among the general public with the panel system; that it was common knowledge that at a typical panel consultation the patient announces what seems to him to be his most prominent symptom and instantly gets a prescription for something supposed to fit his condition; that there is no time for any but the most perfunctory investigation and he is hurried from the surgery almost before he has entered it; that "the human machine does not lend itself to this lightning diagnosis and penny-in-the-slot style of treatment;" that a reasonable time was required, but this the patient did not get and could not hope to get under present conditions.

He roundly declared that "the panel system was a retrograde step, not too strongly described as a disastrous blunder and a miserable failure. It put a premium on scamped work and inefficiency." He wound up by making two suggestions for improvement of the system—namely, to replace the present system by one under which the doctor was paid for actual work done, and the other that the patient should be freed from restrictions both in choosing and in changing his medical attendant.

Naturally enough the coroner's remarks made in open court attracted the attention of many of the London newspapers, who dealt with them each after its own fashion.

The *Evening Standard* published an article which in moderate terms agreed with a good deal that had been said by Dr. Smith and took the view that the advent of the panel spelt the end of personal intimacy between doctor and patient and that the real issue was whether we should return to the old methods or turn our doctors once and for all into State officers. The *Daily Express* said that

the attack "endorses a general charge that the panel patient does not receive medical attention . . . even the most conscientious doctor cannot give to every panel case the care and attention he would feel bound to exercise with a private patient." It declared that the panel system was "in theory a great advance. It brought the boon of medical science to thousands who had relied on empiricism. In practice it is not 'functioning.' That is a reason for new investigation rather than for casting the panel on the scrap-heap."

The *Daily Chronicle* declared that it was not the insurance system that was at fault but the doctor himself and ultimately the Insurance Committees. "Medicine should be like the law—just and impartial and universal. We prefer to believe that these lapses so frequently reported are due rather to overwork or accident than to lack of professional morality."

The *Daily News* took the line that Dr. Smith was exaggerating. It said:

"The case for the present system is not that there is no bad doctoring under it or that the conditions are such as intelligent statesmanship with a perfectly free hand would be disposed to institute in a new community, but that it is a tolerable compromise between conflicting interests in an old and complex society; that it has worked, despite these exceptional cases, better than might have been expected, and that its working is being steadily improved; and that in any case it is an immense advance on the conditions which preceded it. When Dr. Smith denies this, he is merely speaking in his wrath."

It then went on to describe the conditions which existed before the Insurance Act came into force, quoting from an article by Dr. Frank Layton of Walsall, and concluded with:

"If bad treatment is too common under the panel system it was far commoner under the only doctors whom the poor could afford in the old days; and the very poor had no doctoring at all."

The *Daily Graphic* took much the same line. It remarked that Dr. Smith's attack "constitutes a grave

charge not only against the system but against the doctors who carry it out and we should be loth to think it justified in either case."

"The panel system is far from perfect and it admittedly makes possible the scamping of work of which the coroner complains, but no profession has a higher standard of honour than the medical, and by none is that standard more conscientiously observed. But for those facts the panel system could not have been even introduced, and because of them it works in the great majority of cases to the satisfaction of both doctor and patient."

"The average conscientious general practitioner who treats each case on its merits whether he is to be paid for it or not, is well enough content with a system which yields him a steady income and relieves him of the unpleasant business of extracting fees from persons ill able to afford the smallest."

The *Westminster Gazette*, in a very reasonable article, remarked that "mistaken diagnosis is not invariably due to pressure of work. It has been known even in Harley Street."

The Medical Secretary of the British Medical Association had several interviews with press representatives and, in view of the widespread publicity that had been given to Dr. Smith's remarks, issued through the Press Association the following statement:

### Statement by the Medical Secretary.

The attention of the British Medical Association, which officially represents the views of doctors engaged in National Health Insurance work, has been called to the statements made by Dr. Edwin Smith, the coroner for North-East London. In the opinion of the Association Dr. Smith has abused his official position in ventilating his personal prejudices against the panel system, of which he apparently knows little. His statement amounts to an unwarranted attack upon his own profession, for the majority of general practitioners in this country are panel doctors, and if the system is as described by Dr. Smith they are acting in a manner discreditable to themselves and to their profession by taking part in it.

So far from there being "widespread and increasing dissatisfaction of the general public" with the panel system, all the evidence the British Medical Association has is to the effect that the system has greatly improved during the past two or three years, that the evidences of dissatisfaction are largely based on a few individual bad cases, and that the representatives of insured persons are of opinion that with the good will of the medical profession (which they will have) the system, which, it must be remembered, has been a great national experiment, can easily be made into one with which all concerned can feel satisfied.

Dr. Smith's statement that there is no time for any but the most perfunctory examination by the panel doctor is nonsense. The panel doctor is simply a general practitioner who happens to be doing part of his work under the panel system, and if a panel patient requires thorough examination the doctor can give it to him just as well as to a private patient—and he generally does. Dr. Smith is wrong when he suggests that the panel doctor necessarily has a very large number of cases to deal with. The average panel doctor has less than 1,000 insured persons on his list; no panel doctor in any area is allowed to have more than 3,000; and in many districts the highest possible limit is 2,500 or 2,000. There is conclusive evidence to show that the average number of attendances a year per insured person is about 3.6; therefore 1,000 insured persons would amongst them require 3,600 attendances in a year. This means that the doctor with the average list (1,000) would see about 10 insured patients every day. It will be seen, therefore, that even the small number of doctors who have the biggest lists allowed (3,000) would, on an average, not see more than 30 insured persons altogether in a day—that is, inside the surgery spread over two or three sessions, and outside visits. The picture that the coroner asks us to conjure up of the panel doctor with his crowded surgery is either drawn from his imagination or he is asking us to judge the average doctor by the few exceptions.

The only two suggestions he makes for the improvement of the service are that the doctor shall be paid for actual work done, and that the patient should be freed from all restrictions in choosing and changing his doctor. The first point has been considered by the Approved Society Consultative Council, which represents insured persons and acts as the advisory body of the Ministry of Health, and has been turned down. The second point is one which the medical profession has itself proposed to the Ministry of Health—namely, to allow the insured person to change his doctor when he likes, instead of, as at present, only having that opportunity twice a year and very seldom taking advantage of it. No doctor wants to keep a dissatisfied patient.

The Association appeals to the public to judge the panel

doctor as an average general practitioner who does good work steadily day by day—which does not get into the papers.

(Signed) ALFRED COX,  
Medical Secretary.

May 14th, 1923.

We have received a letter from Dr. Burges, vice-chairman of the Birmingham Panel Committee and a member of the Insurance Acts Committee, in the course of which he writes:

The strictures made by Dr. Smith, the Shoreditch coroner, are by no means justified. It is a stab in the back to the 12,000 panel practitioners, most of whom are doing the work conscientiously and thoroughly. The medical profession is a noble one, and I maintain the great majority are honest. If this is so whether we work under the contract system or the private system is of no consequence—the patients will be well attended. If dishonest, again the system is of no consequence. The panel system is all to the advantage of the public; it is to the interest of the doctor to get his patient well as soon as possible, but if he is neglected he can complain, and does complain. The good work done by the many thousand panel practitioners never gets into the papers, but if an expression of opinion could be obtained from our patients themselves it would be an eye-opener to the enemies of the service. Under the panel system the patients are seen privately one by one. Some are trivial cases and require but little time—but a reassuring word from the doctor, who also is the friend of his patient, sets his mind at rest and the little ailment is not heard of again. The serious cases get the attention they require. I have been in practice twenty-five years—fifteen years before the panel and ten years as a panel practitioner. I can state emphatically the workers (and they are the panel patients) are better attended by these 12,000 panel practitioners than they were before the system was introduced. We get to know our patients better, and so can understand them better. The death rate has considerably fallen, largely due to the fact that the insured person can now go to his doctor without considering the fee. Before the panel system so many of the poor waited until they were so ill that the doctor only had a poor chance of pulling them through. My first fifteen years of practice was a nightmare to me on account of the excessive amount of night work. Now the night calls are reduced to a minimum because the patient comes before he is so ill. The first call to a patient in these years before the panel was often a night call—sometimes to a case of pneumonia of three or four days' standing and a fatal ending only too certain; at others a broken-down heart with much distress, with again no hope of pulling the sufferer through. Either case if seen sooner would have in all probability recovered. If our profession could only advertise these facts we should not get these stabs in the back from such men as Dr. Smith. Statements such as these must be refuted. It is not only the panel system that is attacked, but the whole honour of the profession.

### THE PRIVATE CLINIC IN GREAT BRITAIN.

In January, 1922, Sir Thomas Horder gave the mid-session address to the Abernethian Society at St. Bartholomew's Hospital on the subject of the private clinic in Great Britain. As the institution then adumbrated has now taken form, it is worth while to review the scheme set forth in the address, which has been published in pamphlet form, and to record the progress made in the development of the venture.

In his address Sir Thomas Horder recognized three types of private clinic: first, those established in connexion with general hospitals; secondly, those formed by the conversion of a large house into a nursing home with laboratories, such as Duff House or the New Clinic, Windsor; and, thirdly, "group-clinics," which have existed in the United States for some years, but at the time of the address did not exist in this country. Sir Thomas Horder suggested that the group-clinic should confine itself in the first place almost entirely to diagnosis; later, if the institution gained support, observation beds might be added or even a therapeutic institute equivalent to a large private nursing home. Three or four men of equal professional status would group themselves together, adding singly the other representative experts needed to complete the personnel of the clinic. It would, he thought, probably be found that a personnel of twelve would suffice at first, others being added as expert work in other special departments became necessary. The group thus formed would work under one roof, each member having his own consulting room and such additional accommodation as his work might require. A general secretariat would deal with all correspondence, telephoning, and record keeping, but any member would have his own private secretary if he so desired. The group ought not to be too large; the individual members should be chosen not only on account of their expert knowledge and skill in particular directions, but also with a view to their ability to work with one another. The members should have complete freedom to go outside their number for further opinions concerning their

patients; and patients coming to the group-clinic should have free choice of opinions outside the personnel of the group.

The patients seen by a member of the group might be (1) patients sent for his individual examination and opinion as at present, quite independently of the group; (2) patients sent for an opinion by one of the members of the group to whom the patients had been sent individually; (3) patients sent to the clinic as such (the "group-case"); these would either pay a flat rate to include the pathological examination and any expert examinations thought to be necessary, or would be charged a reduced fee for each expert opinion given. On arrival at the clinic a patient would be dealt with by a member of the group, preferably a general practitioner, who, upon the information given by the patient's doctor, would indicate the member or members of the group whose examination and opinion seemed most essential to diagnosis. Each of these members would be able to suggest further investigations if he thought fit to do so. The member of the clinic who might take initial charge of the "group-case" would interview the various other experts, collect their signed opinions, and summarize the position in a report stating the diagnosis and the treatment indicated, which would be sent to the patient's practitioner. As all the expert members of the group would be of consultant status, no patient would be seen unless sent by his general practitioner, and no second attendances at the clinic would be permitted except at the request of the practitioner, who would be free to accompany the patient to the clinic, and suggest the consultant he desired. All the members of the group would consult together concerning difficult cases, and interested practitioners would be invited to attend. Joint reports on particular types of cases dealt with in the clinic should be published from time to time after open conference between the members of the group specially interested.

As we have said, the group form of private clinic suggested by Sir Thomas Horder has now taken shape; and on May 10th members of the Westminster and Holborn Division of the British Medical Association met there (86, Brook Street) for a discussion upon modern methods of investigation of abdominal diseases, conditions pre-eminently suitable for group examination. The discussion was opened by Sir Thomas Horder and continued by Mr. Clayton-Greene, Dr. Gilbert Scott, Dr. Jockes, and Mr. Arthur Evans, all of them members of the group. The speakers dealt mainly with the condition of chronic abdominal pain, and gave illustrations of the advantage to be derived from combining facilities for investigation under one roof, and from consultation with their colleagues in difficult cases. Subsequently Dr. Gilbert Scott gave a demonstration of x-ray examination with the opaque enema; and the members of the Division were able to inspect the organization of the clinic. It appears that, as Sir Thomas Horder predicted would be the case at the beginning of the venture, the number of "group-cases" seen is not very large; and the members of the group are at present chiefly occupied with their own patients.

The ground floor of the clinic contains a large waiting room for patients. On the floor above Dr. Drury Pennington, to whose exertions it is in large measure due that the scheme materialized, has his room, where he interviews "group patients" on their arrival. Each member of the group has his own consulting room, with a small dressing room attached, and accommodation for patients while waiting to see the particular consultant to whom they have been directed. On the first floor also is the x-ray department, and on the second the pathological department. At the present time the group consists of fourteen members; but some other experts in special subjects ("associates") are available when needed. The patients are charged a flat rate for the consultation and investigations required, but the precise amount varies to some extent according to the requirements in the way of prolonged pathological or x-ray examination. When the dossier of the case is complete, the members of the group who have been concerned in the investigation meet for discussion, and the general practitioner of the patient is invited to attend this discussion.

In his address at St. Bartholomew's Hospital Sir Thomas Horder enumerated the following cases as suitable for "group diagnosis"—chronic toxic processes, whether microbic or metabolic, arthritis and fibrositis, many gastrointestinal disorders, and a large group of neurasthenics. He dealt also with various objections and difficulties that have been raised, or are likely to arise, in connexion with group-clinics. Thus in the United States some of the clinics are too large, so that the whole process becomes mechanical, and the patient is sent on a "circular tour" from which he emerges with a voluminous and extensive dossier, but with no considered judgement as to the essential nature of his malady. It has been urged also that the group system will eliminate the general practitioner; but in the opinion of Sir Thomas Horder this will not be so. Rather will the general practitioner come to regard the group as relieving him of the intolerable burden of knowing that in many cases he is not giving all the help that can be given because he has not had the expert knowledge necessary for all the investigations required for diagnosis. The objection that the group clinic must lead to unnecessary duplication of examination should not arise in practice where the members of the group work harmoniously together. The danger of the formation of cliques must be guarded against by drawing the members of a group from different schools, by making groups overlap, and by retaining power to the patient and to any member of the group to obtain outside expert opinion.

Sir Thomas Horder concludes his exposition of a very interesting experiment by expressing his belief in the "urgent desirability of great and even drastic changes in medical practice." In his opinion "our profession should take the lead, rather than be forced by the public to follow a less wise lead taken by itself, in the direction of making our art more efficient, more rational, and more attractive."

## Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

### *Dangerous Drugs and Poisons (Amendment) Bill.*

THE Dangerous Drugs and Poisons (Amendment) Bill was taken on report in the House of Lords on May 10th.

On Clause 2 the Earl of Onslow moved a drafting amendment in order to correct an unintended construction. As the bill stood, words in Clause 2 might be read as meaning that all offences were indictable and that the consent of the Attorney-General was required even for summary proceedings. Instead, it was proposed to begin the subsection: "Subject as hereinafter provided no persons shall, in England or Wales, be proceeded against by indictment for an offence under this Act unless the proceedings are instituted . . ." Then would follow the reference to the Attorney General or the Public Prosecutor. The amendment was agreed to.

Earl Beauchamp afterwards moved an amendment with the object of relieving the inadvertent retailer, who by a mistake of his own, or by his agent's mistake, offended against the law. There would, Lord Onslow pointed out, be great difficulties in administering the law on the lines suggested, and the amendment was negatived.

Lord Dwyer next moved an amendment to permit a pharmaceutical chemist to administer in an emergency and in good faith without any medical prescription any of the drugs to which Part 3 of the Act applied. The Earl of Onslow said that to give chemists a statutory right—for that is what it would amount to under the amendment—to administer these drugs at their own discretion would be a very serious matter indeed. It would place the chemist in a semi-medical position and would be strongly criticized by the medical profession generally because these particular drugs, especially one—cocaine—could not really be safely administered by persons who had not a medical training. The Pharmaceutical Society did not suggest this amendment nor officially support it. Any representations which might be made in regard to the regulations would, of course, be most carefully considered by the Home Office. Lord Dwyer did not press his amendment, and it was by leave withdrawn.

Two other drafting amendments were afterwards agreed to.

### *Vaccination and Small-pox Statistics.*

In reply to Mr. T. Thomson, on May 8th, Lord E. Percy (for the Minister of Health) stated that the total number of deaths certified last year as due to small-pox was 27, but one of these cases was probably incorrectly diagnosed. Of the remaining 26 cases, 11, whose ages varied between 43 and 74 years, had been vaccinated in infancy but not since, 10 were unvaccinated, 3 showed no evidence of vaccination, and 2 were vaccinated during the incubation period of small-pox. According to the information at present available the total number of cases of small-pox occurring in vaccinated persons last year was 275, and the percentage of deaths among cases in this class, irrespective of age, was 4. The total number of unvaccinated cases, including those which showed no evidence, or were vaccinated only during the incubation period

of small-pox, was 687, and the percentage of deaths from cases in this class, irrespective of age, was 2.1. Of the 26 fatal cases 24 occurred in the outbreak of virulent small-pox in London and the neighbourhood, and in this outbreak the fatality rate was 23.7 per cent. in the case of vaccinated persons and 60 per cent. in the case of unvaccinated persons.

Mr. Chamberlain, on request for a comparison of the figures of vaccination of newly born children in the years 1907 and 1921, stated that in the year 1907 10.9 per cent. of these children were vaccinated, and in 1921 the percentage was 38.3. The total number of exemptions from vaccination in 1907 was 76,709, and in 1921 it was 382,155. Figures for 1922 are not yet available.

At the instance of Mr. Becker the Minister of Health, on May 9th, gave the following particulars of small-pox cases during the last three years:

Period.	No. of Cases Notified.	Other Cases Reported but not Notified.	Cases Subsequently Withdrawn or not Regarded as Small-pox.	Net Total of Cases.
1921 ... ..	343	23	30	336
1922 ... ..	1,042	17	80	979
1923 (first three months)	533	5	18	520

On an inquiry as to small-pox cases in Doncaster Mr. Chamberlain said, on May 9th, that in no case had small-pox occurred in that town after recent vaccination where the interval between vaccination and the development of the disease had exceeded fourteen days, nor was he aware of the occurrence of any such case elsewhere during the past two months.

### *Health at the International Labour Conference.*

Sir Montague Barlow, on May 9th, asked the House of Commons to approve of the policy of the Government at the third and fourth sessions, in 1921 and 1922, of the International Labour Organization, which is a development of the League of Nations; one or more conferences are held each year, and each State can have four representatives—two for the Government, one for employers, and one for workers. Draft conventions adopted are intended to be a basis for legislation in the various countries, and the recommendations approved have for their object to affirm principles to be carried out. Sir Montague spoke of the compromise in regard to the convention as to the use of white lead in painting. By this convention the use of white lead or lead sulphate in the internal painting of buildings would be prohibited, subject to several definite exceptions. The employment of males under 18, and of all females, would with certain exceptions be prohibited in any painting works of an industrial character involving the use of white lead. To enable employers to adapt processes these provisions would not apply until November, 1927. Regulations designed to be of earlier application would limit the use of white lead for painting either to a form of paste or to paint ready for use; the danger was largely ascribed to dust. Statistics of lead poisoning amongst painters would be kept. These provisions were to be applied not later than January, 1924. The compromise had been rather hastily settled, and would have to be considered further by the executive at Geneva. The Maritime Draft Convention would make compulsory, except in urgent cases, the medical examination of all children and young persons under 18 years of age employed on shipboard. The examination was to be repeated once a year. The Government proposed to introduce a bill to give effect to these provisions. For the same reasons which prompted the late Government to refuse to ratify the Washington Maternity Convention for industry generally, the Government did not propose to accept the recommendation dealing with the protection before and after childbirth of women wage-earners in agriculture. The reason was that the Washington maternity proposals affected only women who were engaged in industry. The English provisions, under the Insurance Act, affected not only women engaged in industry, but the wives of employed contributors under the Act. Further, the schemes of local authorities with State Aid Grant provided various services for all women. After considerable debate an amendment by Mr. Clynes, that the House should declare in favour of the ratification of the various conventions instead of approving of the qualified support by the Government, was rejected by 176 to 235.

*Royal Army Medical Corps.*—In reply to questions by Dr. F. E. Fremantle, Mr. Gwynne (Financial Secretary, War Office) said that an unsettled feeling had been caused in the army generally by uncertainty as to the future establishment and rates of pay, and by the conditions of service that had prevailed during the period of reconstruction after the war. In the case of medical officers the attractions of the civil professions had doubtless reinforced those causes. It was hoped that the army would now be able to return to normal settled conditions, and it was not proposed at present to take any special steps in regard to the Royal Army Medical Corps. He was aware that there was a shortage of candidates at the only examinations which had been held since 1914 for commissions in the Royal Army Medical Corps. This might have been due to the short notice given. It would, however, be easier to gauge the situation when the next examination, due in August, had been held. Dr. Fremantle asked also whether it was not the case that formerly it was recognized in the pay warrant that officers of the Royal Army Medical Corps, owing to their long and expensive training and their necessarily higher age on joining, could be attracted only by special conditions, including a higher rate of pay and pension than other officers, but that recent changes in the warrant had tended to abolish this differentiation, and that

sufficient increase had not been made in the pay of the Royal Army Medical Corps to compensate for the increased cost of living since the war. Mr. Gwynne said that officers R.A.M.C. still enjoyed special conditions as regarded pay and retired pay, and he was not aware that the essential financial conditions of a sound medical service for the army were absent to-day. Army pay generally was about to come under review.

**Dentists Act (1921) Amendment Bill.**—Lieut.-Colonel Dalrymple White, on May 9th, introduced a bill to amend the Act of 1921. The main proposal, he said, was to enable ex-service men who were unregistered dentists to enter for the qualifying examination at the age of 21 instead of 23, as laid down in the Act as the fixed age for all unregistered dentists. The number of men who would come under the provision of this bill would not be very large, but he hoped that it would be sympathetically received. The bill was given a first reading. It is backed by Colonel Sir Charles Burn, Mr. Hohler, Mr. Lumley, Sir Arthur Marshall, Mr. J. H. Thomas, and Lieut.-Colonel Lambert Ward.

**Tuberculosis in Canadian Cattle.**—Lieut.-Colonel Fremantle asked a question, on May 9th, with reference to the report of the medical officer of health to the Manchester Port Sanitary Authority to the effect that the first batch of Canadian cattle was not altogether free from pulmonary tuberculosis. Sir Robert Sanders said that Canadian store cattle imported into this country were not required to undergo a test as to freedom from tuberculosis. Cattle affected with tuberculosis to a dangerous degree could be dealt with under the Milk and Dairies (Amendment) Act, 1922. In reply to questions by other members he said that the general report on the cattle was that they were very healthy. He had no power to order the isolation of the cattle affected, and he did not, therefore, see that any useful purpose would be served by attempting to trace them. A notable proportion of the cattle of all countries was affected by tuberculosis, and it had been found possible to deal with tuberculosis in British cattle only within the narrow limits prescribed by Section 5 of the Act of 1922. The conditions regularizing the import of breeding animals were under discussion, and he was endeavouring to frame such regulations as would confine the admission to the high-grade stock to which alone the agreement with the Canadian representative referred. Lieut.-Colonel Fremantle inquired, on May 14th, by what pledges, if any, the Minister of Agriculture was debarred from testing imported Canadian breeding cattle for their healthiness. Sir Robert Sanders replied it was provided in Section 2 of the Importation of Animals Act, 1922, that Canadian breeding cattle could be admitted only by the authority of an order made by the Minister of Agriculture under this section; an essential condition to be prescribed in the order was the production of a certificate issued by a duly authorized officer of the Dominion of Canada to the effect that the animals were within one month before shipment effectively tested for tuberculosis and were found free therefrom.

**Yaws in the West Indies.**—Dr. F. E. Fremantle asked, on May 14th, what payment had been made to the medical officers in the West Indian Colonies who had carried out treatment of yaws on an intensive system during the past four years; and what saving to the revenue had been effected by closing the hospital in Grenada owing to the success of this treatment. Mr. Ormsby-Gore replied that the medical officers in Grenada undertook to perform this work without additional remuneration, but as the committee appointed to inquire into the Windward Islands medical service had recommended that some special allowance should be granted, the matter, together with the other recommendations of the committee, was receiving consideration. The Yaws Hospital was closed at the end of 1921. The cost in that year was £902, but as a certain amount of treatment was still being carried out he was unable to say what proportion of this sum represented a saving.

**Colonial Medical Practice.**—Dr. F. E. Fremantle asked, on May 14th, in which colonies it had recently been considered necessary to amend the ordinary medical practice in order to enable persons not holding a medical qualification to practise in the United Kingdom to practise in the colonies. Mr. Ormsby-Gore said that the only three colonies in question were British Honduras, Turks Islands, and St. Vincent. His Majesty had not been advised to disallow the ordinances, but in two of the three cases the Governor had been instructed not to use the power conferred upon him without previous reference to the Secretary of State except in emergency. The Secretary of State attached great importance to the maintenance of a high standard of professional standards in the Colonies, but he recognized that there were instances in which rigid adherence to rules in the United Kingdom was impracticable in some of the poorer or less developed communities.

#### Answers in Brief.

The number of whole-time medical officers in the employment of the Ministry of Pensions is 511, of whom 374 served overseas, 104 served at home, and 33, or 6.5 per cent., had had no military service.

The gross expenditure of local authorities on tuberculosis treatment during the financial year ended March 31st, 1923, was estimated to amount to £2,813,610, exclusive of capital expenditure for which particulars were not yet available.

Instruction in lip reading is provided by the Pensions Ministry for ex-service men likely to benefit by it. After a certain amount of instruction, proficiency was entirely dependent upon regular practice, and the Minister's advisers considered that a course of twenty-five lessons afforded the man of average intelligence ample opportunity of acquiring facility in the art. Experience had shown that the unlettered man of less than normal intelligence was not capable of benefiting.

It has been decided to retain Queen Alexandra's Convalescent Centre at Saltash for a limited period for the treatment of neurasthenic pensions patients.

## England and Wales.

### BACTERIOLOGICAL DEPARTMENT, NEWCASTLE.

The new building of the Bacteriological Department of the University of Durham College of Medicine, Newcastle-upon-Tyne, will be opened on Friday, May 25th. The visitors will be received by the president of the College of Medicine, Sir David Drummond, in the King's Hall, Armstrong College, at 4.30 p.m., and Sir Frederick William Andrewes, M.D., F.R.S., will give an address at 5 p.m. Afterwards the building will be open for inspection.

### LIVERPOOL OPEN-AIR HOSPITAL FOR CHILDREN.

According to the report for 1922 of the Liverpool Open-air Hospital for Children, Leasowe, Cheshire, the income for the year amounted to £25,414, nearly all of which was received in grants from the Liverpool Corporation, the Lancashire County Council, and other public bodies; the expenditure for the year, including extraordinary expenditure, amounted to £25,443. Dr. Hartley Martin, the senior medical officer, in his report on the results obtained from treatment in the hospital as deduced from the state of health of the cases discharged during the year, said that of the 186 cases discharged, 20, or 10.7 per cent., were non-tuberculous. Of the 166 tuberculous cases discharged, 134, or 80.15 per cent., were discharged with the note "disease quiescent"; as 12 cases were removed by their parents before the completion of treatment, and 2 cases were transferred on account of infectious disease, the figure which represented the results achieved in all cases treated to completion was 88.15 per cent. The percentages showing the results achieved from Liverpool cases only were 85.5 and 93.9 per cent.; this is held to show the advantage of working in close conjunction with the tuberculosis dispensaries and the hospital out-patients' departments, so that cases were admitted as soon as diagnosed and in many cases for diagnosis. Owing to the cloudy summer of 1922, the usual routine exposure of the children to sunlight could not be practised and the marked improvement in the health of the children which followed this exposure could not be achieved. This partly explained the reason for a falling off in the number of cases discharged, the children being retained in hospital for a longer period than usual. The same cause interfered with the work of investigating the blood response to sunlight, which had been begun during the summer of 1921; it was then observed that the phagocytic power of the blood, as indicated by the differentiated nuclear leucocyte count, was improved as the result of exposure to sunlight, and that the health of the child improved *pari passu* with this. An attempt was made during the winter months to produce this result by exposure to radiant heat, but the results achieved were not satisfactory.

### AMBULANCE ARRANGEMENTS IN LONDON.

In view of reports in certain newspapers to the effect that undue delays sometimes occurred in the arrival of ambulances to carry urgent cases in London, and of questions in Parliament (see, for instance, JOURNAL, April 7th, 1923, p. 606), the Metropolitan Asylums Board, has issued a report on the ambulance service it provides in London. It has 107 motor ambulances and omnibuses, accommodated at six ambulance stations in different parts of London, and a large repair dépôt at Fulham. The primary function of the Board's ambulance service is the removal of cases of infectious disease in the metropolis, but patients are also removed to the other institutions of the Board for tuberculosis, sick and convalescent children, and mental deficients. Apart from this work the Board's ambulance service has been largely utilized for the removal of non-infectious cases from private houses to hospitals, for which service a fee is charged (ten shillings a journey within the administrative county of London, with an additional charge when a nurse is supplied). In 1922, out of a total of 51,767 removals, 33,679 were to the infectious and 4,807 to the non-infectious institutions of the Board, and 13,281 were removals from home to hospital, infirmary, or elsewhere, or return journeys. In 1906 a departmental

committee was set up by the Home Secretary, to inquire as to the provision made for dealing with accidents and sudden illnesses in the streets and public places of London, and two of the three members of the committee reported that the most efficient and economical plan would be an extension of the non-infectious system of rapid ambulances initiated by the Metropolitan Asylums Board. In 1913 the London County Council invited the Board to prepare a scheme of co-operation with it and other metropolitan authorities for the establishment of a street accident ambulance service, but the scheme was not accepted, and in 1915 the County Council set up the existing street accident ambulance service. The present position is that the London County Council has a free ambulance service to deal with street accident cases, while the Metropolitan Asylums Board has a service which deals with removals to infectious and other hospitals and is able and willing to deal with removals of all kinds, other than street accidents.

#### THE CITY OF LONDON TRUSS SOCIETY.

The 113th annual festival of the City of London Truss Society was held at the Abercorn Rooms on May 8th, when the Lord Mayor of London presided, supported by the Sheriffs. The Lord Mayor mentioned that since its foundation the Society had been the means of affording relief to 6,706,000 persons suffering from hernia. Every patient attending at the institution was seen by the surgical staff. A stock of about 2,000 trusses was kept on the premises, but there were as many as eight or ten cases a day in which the ordinary truss would not prove efficient, and in those cases special instruments were ordered. The ages of the patients treated by the Society varied within the widest limits; the youngest on record was an infant 7 days old, and the oldest a woman of 105! Mr. Sheriff Studd acknowledged the indebtedness of the institution and its beneficiaries to the surgical staff, and Mr. G. L. Keynes, surgeon to the Society, responded. Mr. Keynes said that the professional knowledge and skill now available for these ruptured patients were of a very high order, but this was not due to the special genius of himself or of his colleague, Mr. R. Coyte, the assistant surgeon; it was due to the fact that they had one hundred years of that institution's experience to draw upon—an accumulated experience unique in this country. The necessity for trusses was not as great as formerly, but the fact was that a large residue of older persons could not be treated by operation. The number of special trusses now provided was about a thousand a year and showed a tendency to increase.

## Scotland.

#### NEW REGULATIONS FOR MEAT INSPECTION.

IMPORTANT regulations have been issued by the Scottish Board of Health with a view to securing uniformity of meat inspection. They are dated April 20th, 1923, and are entitled "Public Health (Meat Inspection) Regulations (Scotland) 1923," and have followed upon an inquiry which began in 1914, when the Board instructed one of its medical officers, Dr. Gerald Leighton, to investigate the question of establishing a uniform system and standard of meat inspection for Scotland. The inquiry was resumed after the war and three committees of experts assisted in the investigation. The most important provision in the regulations is Article 4, which provides for a system of detention and seizure of unsound meat. Certain officials with sufficient training and experience, who, in general, will be certificated sanitary officers, to enable them to recognize any departure from the normal in a carcass, are to be entrusted with the work of a primary inspection and power to pass carcasses which are obviously sound, and to detain all carcasses that show any departure from the normal for final judgement by the qualified meat inspector. The latter will be a veterinary surgeon or medical officer of health. There will thus be two grades of officials concerned in meat inspection known respectively as the detention officer and the meat inspector. The Board of Health

recognizes that the inspection of carcasses in private slaughterhouses; especially in widespread rural areas, is one of great difficulty; it considers that the best measure which can meantime be taken is to regulate the days and hours during which slaughtering may take place in each slaughterhouse and to arrange that a detention officer shall visit each slaughterhouse as often as possible during the times so fixed. An emphatic opinion is, however, expressed that private slaughterhouses should be abolished, and replaced by public abattoirs owned and controlled by the local authority. In the case of carcasses of bovines slaughtered for emergency reasons, such as sickness or accident, the Board recommends that very careful inspection should be made by a veterinary surgeon or the medical officer of health. The Board does not consider a distinctive mark upon the carcasses passed as fit for food absolutely necessary, except in the case of such as are sent from the area of one local authority into that of another. Attention is drawn to a very undesirable practice said to be increasing in some towns—namely, the practice of hawking meat from baskets, barrows, or small carts. Such meat is probably uninspected, is of doubtful origin, and is specially liable to contamination by dust, handling, and unsuitable storage of unsold meat overnight. This matter is controlled by registration of meat sellers under Article 10. The registration of places of cold storage, and the inspection not only of meat, but of meat products and game stored in them, is controlled by Article 11 of the regulations. The question of *ante-mortem* inspection of animals consigned for purposes of food also forms matter for a recommendation; in some districts a veterinary surgeon attends all sales of fat stock and in this way diseased animals are often detected; if they are subsequently transferred from the area of one local authority to that of another, the latter should be notified of the fact.

#### GLASGOW MEDICAL LUNCH CLUB.

The thirty-seventh meeting of this club was held on May 10th in Ferguson and Forrester's restaurant, when the President, Dr. W. L. Reid, occupied the chair, and a very representative gathering of members attended to welcome as their guest of honour Sir Samuel Chisholm, Bt., who almost a quarter of a century ago was Lord Provost of Glasgow. In his address after lunch, Sir Samuel harked back to the year 1900, when during his term of office small-pox broke out in the city and rapidly became epidemic. Apart from the danger which thus threatened the population, an international exhibition had been arranged for the following year, and over half a million pounds had been raised as a guarantee fund. It was clear that the success of the venture would be seriously jeopardized unless the epidemic could be arrested. He described the excellent work done by the medical profession of the city in conjunction with the sanitary authorities in the thorough revaccination of the inhabitants. A large and well organized band of trained vaccinators was sent to the different areas of the city, particularly to slum districts, model lodging houses, and police courts. Thanks to the energetic measures adopted, and to the thorough co-operation of the medical profession, the epidemic was arrested. The city was thus not only freed from the epidemic, but the systematic revaccination of almost the entire population conferred upon the inhabitants a large measure of immunity against future attacks. He appealed to the medical practitioners of to-day to emulate the good work of 1900, and to strive to maintain the health of the city at a high standard. The Vice-President, Dr. John Henderson, expressed to Sir Samuel the thanks of the members for his presence and for his interesting address.

#### INSTITUTIONAL TREATMENT FOR MENTAL DEFECTIVES.

The Edinburgh District Board of Control is purchasing Gogarburn House for the Edinburgh Town Council for the purpose of institutional treatment of mental defectives belonging to the Edinburgh Lunacy District. The property, which is an old mansion standing in grounds, was acquired by the town council some years ago as a convalescent home for the treatment of children under the maternity service and child welfare scheme. It has now

agreed to accept the offer by the Lunacy Board of £11,500 for the property, which represented what they had paid for purchase and alterations.

#### LEGACIES IN AID OF EDINBURGH BLIND.

At a meeting of the managers of the Edinburgh Royal Blind Asylum intimation was made of two legacies from the estate of the late Mrs. Sara Phyllis Katherine Duncan, one of £400 to the institution and one of £600 to the Blinded Soldiers' and Sailors' Hostel, Newington House, Edinburgh. A legacy to the Blind Asylum of £1,000 by the will of the late John A. Forrest, W.S., was also intimated.

## Ireland.

#### ROYAL COLLEGE OF SURGEONS IN IRELAND.

The Royal College of Surgeons (Ireland) presented recently the following address to Mr. T. M. Healy, Governor-General of the Irish Free State:

"May it please your Excellency.—We, the President, Vice-President and Council of the Royal College of Surgeons in Ireland, wish to greet you on your appointment as the first Governor-General of the Irish Free State, and to express the earnest hope that your tenure of that high office may be both long and prosperous, and rendered illustrious by the establishment of peace and prosperity within the border of the Irish Free State.

"Since its foundation, in 1784, to the present date, the College has endeavoured to discharge its functions with efficiency and as an educational body to fulfil its duties and obligations to the country. Its Fellows and Licentiates are found on the staffs of nearly every hospital in Ireland, and many hold leading positions in the great medical and scientific institutions in the Colonies abroad.

"We can assure your Excellency that the services of our College will on all occasions be placed loyally and wholeheartedly at the disposal of the Government of the Irish Free State wherever questions arise affecting the public health or the welfare of the people."

The Governor-General, in reply, said:

"Mr. President and gentlemen of the Royal College of Surgeons in Ireland.—Your greetings on my appointment as the first Governor-General of the Irish Free State afford me great pleasure. They come at a moment when it seems possible that tranquillity may be re-established within our borders. Surgeons, no doubt, gain experience in warfare, but they can profit only by a guarded peace. Your College has, as an educational body, discharged splendid functions. Nearly every hospital in Ireland, and many abroad, have been strengthened by the attainments and zeal of its Licentiates and Fellows.

"Irish surgeons are justly esteemed for their skill, originality, and courage wherever they practise. Medicine, leechcraft, and inoculative science daily win fresh triumphs over disease. The knowledge which is yours may, therefore, be regarded as the treasure house of the community.

"I thank you for the assurance that your services can be counted on by the Irish Free State, to aid it in preserving the public health and welfare of the common people."

The members of the deputation representing the College were: Sir William I. de C. Wheeler, president; Mr. R. C. B. Maunsell, vice-president; Sir Lambert Ormsby, secretary; Sir Thomas Myles, Sir Arthur Chance, Sir Conway Dwyer, and Mr. Alfred Miller, registrar.

The deputation afterwards had luncheon with the Governor-General.

#### SALARIES OF MEDICAL OFFICERS.

A deputation of the dispensary medical officers in the Connemara district recently waited upon the Co. Galway Central Hospital Committee and presented the following statement as to the inadequacy of their present salaries:

"The Connemara doctors are at present very badly off financially; many are in debt, and their heavy travelling expenses swallow up almost their entire income. Their work has been increased by the abolition of the district hospitals, and they have received nothing to make up for the increased cost of living; the salaries paid are lower than those paid in the eastern part of the county, lower than those paid in other parts of Ireland where good private practice is to be had. Private practice is nil in some parts of the county, and doctors have to travel vast distances, often up to 200 miles a week, to attend to dispensary patients. Connemara is a hotbed of tuberculosis, typhoid, and typhus, and many doctors have lost their lives in the course of their duty. The salaries paid are lower than the wages of a tradesman, and the net salaries, after deducting expenses, are often less than that paid transport union labourers. A good shop assistant or a country council clerk would refuse to work for the small remuneration paid.

"Suggestions: (1) That a salary of £350 rising to £500, together with actual travelling expenses, should be paid; (2) that all dis-

pensaries should be graded; (3) that appointments to the better class districts should be filled by the promotion of doctors from poorer areas."

The Chairman said that all the Committee could do was to make a recommendation to the Board of Health. It seemed to him that the only way to deal with the salaries was to fix a flat rate. The Government ought to be asked to do in Ireland what the British Government had done in the Highlands and Islands of Scotland. After the application of the medical officers was fully discussed the Hospital Committee made the following recommendation to the County Board of Health: That the salary should be £300 per annum with annual increments of £5 until a maximal salary of £350 is reached; the annual increments to be applied retrospectively. The Committee decided to take no action with regard to the second and third recommendations put forward by the doctors as to the grading of the districts for the purpose of promotion. The County Board of Health has adopted a flat rate of £300 per annum for all the dispensary doctors in co. Galway, including those in the Connemara area.

The Ministry of Home Affairs (Northern Parliament) has informed the Ballymoney Board of Guardians that after careful consideration of the report of the inspectors—Mr. Robinson and Dr. Patrick—the Ministry is satisfied that the salaries of the medical officers of the union are too low, having regard to the service rendered by the medical officers, the cost of living, travelling expenses, and to the salaries paid in other unions of similar character. The Ministry, having reviewed all the circumstances, considered that it would not be justified in prescribing a new scale of salary, and that it was better to pay medical officers a fixed salary instead of a scale salary, and that the amount should be such as to offer reasonable remuneration for the work required. Having regard to all the circumstances, they thought that £225 would be a reasonable salary to pay in Ballymoney Union, except in Portrush district, where, as the work was not so heavy as in other districts, £200 per annum would be sufficient. The Ministry proposed to fix the salaries of these officers at these figures, but before making an order desired to afford the guardians an opportunity of paying their medical officer at the rate specified, so obviating the necessity for an order. The Ministry considered that the revised salaries should have effect as from October 1st, 1922.

## Correspondence.

#### TREATMENT OF PUERPERAL INFECTIONS.

SIR,—The question of the best method of dealing with puerperal infections is of the deepest concern to every practitioner in the kingdom. Professor Watson's interesting communication should be reviewed in conjunction with the discussion which followed the reading of his paper (BRITISH MEDICAL JOURNAL, March 24th, 1923, p. 505; discussion, p. 511). In the last sentence of his reply to the discussion Professor Watson says, "If in the meantime death occurred it was due to bacteraemia, which would only have been aggravated by interference." This is surely the acme of advanced obstetric thought, but conveys no practical help to the general practitioner. The same comfortable scientific cloak may adorn the mind of the practitioner who allows a gangrenous appendix to kill his patient. We may well ask if this conforms to present-day surgical principles. The discussion, as published in the BRITISH MEDICAL JOURNAL, was of great interest and deserves close study; while most of the speakers agreed to some extent with Professor Watson's ideas, their words contain faint praise for treatment based upon the retention of foreign decomposing matter in the uterus.

I have been engaged in general practice for just over a quarter of a century, and for many years have sufficiently enjoyed the confidence of my colleagues in neighbouring towns and villages to be asked to share their anxieties and responsibilities in these distressing cases. The treatment I adopt is based on the principles I saw carried out in the Rotunda under the mastership of Dr. Purefoy, while studying for the L.M. The results in my last seven cases are of some interest. Five of the practitioners who

sought my aid sent for me as soon as they found conditions abnormal, and the five cases were removed to my wards in the Dumfries and Galloway Royal Infirmary, and treated under as careful and thorough technique as we carry out in our routine for abdominal section. They all recovered. In two cases manipulation had been undertaken before I was called in; one case had been curetted, both had been douched. My treatment in these two cases was carried out in the homes of the patients on similar lines to those I adopt in hospital practice, but there can be no comparison. Home treatment is a very poor substitute. Both cases were late cases and both died. I would like to ask Professor Watson if I am justified in drawing from his paper the conclusion that he would regard these two cases as having been aggravated by the treatment we adopted. The conclusions I myself draw are, that if any form of manipulation is to be undertaken it must be early and under hospital conditions.

During the war I had a priceless experience as officer in charge of the surgical division of the 21st General Hospital. I there had the opportunity of observing closely the work of several well known surgeons. We received cases from various casualty clearing stations. Many wounds had been "bipped." From one casualty clearing station the results, where this treatment was adopted, were uniformly good, but had we based our opinion on cases drawn from other sources I fear we would have arrived at the conclusion that this form of treatment was futile. Results depend, not on the method, but, if I may so put it, on the method of the method.

We groan to-day under a multiplicity of methods of treatment in all branches of surgical practice, and the tendency of teachers is to overlook the fact that it is the laborious, often wearisome, attention to apparently trivial details which brings success in individual cases and which, if followed in every midwifery case, would render puerperal sepsis rare. We in country areas, who drink from many fountains, cannot but be surprised that a new well of knowledge has been tapped. The waters are bitter; we are asked to throw over the methods of treatment taught us by those whose memory we revere, and who claimed for their treatment reasonably good results, and which in our own hands have proved satisfactory. I would not myself quarrel with the use of a blunt curette in those cases, although I prefer gauze, but I very often do quarrel with the method in which the curette is used. The curette must at all times be used with great delicacy and restraint.

Dr. Dudley Boswell's reference to his cow which calved, and what I see in this rural area, suggests that the cow is much more tolerant of puerperal infection than the human female. If this is an accepted view, would it not be advisable, in preparing serums for those conditions, to obtain them from the cow's blood? The mare, I think (but my experience is very limited), is very much less tolerant. Professor Watson has placed us under a deep obligation in bringing before us so stimulating a paper. If there is any golden thread to which we may cling for guidance, it is, "Don't let sepsis occur."—I am, etc.,

GEORGE R. LIVINGSTON, M.D.,  
F.R.C.S. Ed.

Dumfries, May 8th.

#### CATGUT OR SILVER AS SUTURE FOR VESICO-VAGINAL FISTULA.

SIR,—In your issue of May 12th (p. 834) Dr. Blair Bell writes with reference to a report of the Gynaecological Congress in Edinburgh in your issue of May 5th, which, as he says, is "a perfectly accurate one."

This is what this report says: "He [Dr. Blair Bell] did not claim to cure every case, however, as Dr. Herbert Spencer said could be done if silver wire were used." There is not a word in the report about Dr. Blair Bell's having cured his cases after two or three attempts, nor am I reported to have stated that these cases could always be cured at the first attempt by silver wire, a statement which I have never made. It was Dr. Blair Bell's admission of failure and my not knowing then that he had cured the cases at the second or third attempt which led me to remark that in my opinion they could all be cured by the use of silver wire, passed by means of a hollow needle.

I brought the subject of silver wire before the Congress in the hope that it might enable members, as it has enabled me—after the failure of catgut in most experienced and skilful hands—to rescue a patient from the consequences of such a mode of treatment as had been adopted by a surgeon in Dr. Haig Ferguson's most instructive case.

Dr. Blair Bell is quite right in supposing that I should regret any misunderstanding, and I hope this statement will make the position clear.

In all my operations for vesico-vaginal fistulae silver wire has been used, and—with the exception of one case in which a recto-vaginal fistula and a vesico-vaginal fistula occurred as a result of a too successful removal of cancer by radium—every case has been cured, though not always at the first attempt.

In view of the statement in your report that "he did not claim to cure every case," I ask Dr. Bell if he has cured every case of vesico-vaginal fistula he has operated on by means of catgut.

Dr. Blair Bell says that the use of silver wire is a retrograde step. A little retrogression from ground liable to infection with tetanus (as catgut is) has its advantages. Within the last few days I have seen two gynaecologists who have lost three patients from tetanus owing to the use of catgut, and the colleague of one of them had lost another patient from the same cause. There is no such risk with silver wire. In my opinion it is more scientific to use silver sutures, which are removed, than to leave in the bladder buried stitches of any material whatever. Of course, in any operation the technique must be good to secure success.—I am, etc.,

London, W., May 12th.

HERBERT R. SPENCER.

#### PERNICIOUS ANAEMIA.

SIR,—In the JOURNAL of April 28th (p. 743) Dr. Knyvett Gordon takes Dr. Coates to task for publishing as pernicious anaemia a series of cases which included examples of sprue, etc. Dr. Coates seems to pin his faith to the "idiopathic" criterion of what shall and what shall not be called "pernicious" and will thus, if he is not wary, be one day defeated by a case of bleeding piles. For Dr. Knyvett Gordon the criterion of perniciousness is "a lethal change in the bone marrow" and this, he says, must be accompanied by persistent presence of megaloblasts in the blood, free iron in the liver, etc. He further seems to suggest that these changes are non-specific and may be grafted on to any kind of anaemia as a terminal event. His remarks are addressed to the subject of what facts must be demonstrated to "establish a pathological diagnosis of pernicious anaemia" (the italics are mine).

I wish, on behalf of the poor clinician, to take the gravest exception to the suggestion that the establishment of a particular form of end-process, admittedly common to various clinical conditions, by the pathologist gives him the slightest right to limit the use of such well recognized clinical terms as "pernicious anaemia."

If the term "pernicious" must be used, I submit that it must be used as a clinical term and applied to the syndrome with which it is already associated. This syndrome has many features, not all of which are present in every case—for example, glossitis, gastric and intestinal symptoms, combined degeneration of the cord, etc. Except that there is present an anaemia of haemolytic type, and this can be discovered by suitable examination of the blood, urine, etc., we have no haematological criterion of value in diagnosis. This type of anaemia is not by itself absolute evidence since it occurs in a variety of other conditions. Diagnosis is to be made by careful consideration of the whole of the symptoms, any one of which may be found in other cases, although there is no other disease which presents them in the same grouping. This, I believe, is the general opinion of clinicians, but we are apt to have set against it the suggestion originating on the Continent that there is something characteristic in the blood picture and so constant that without it pernicious anaemia cannot be said to exist. The argument is even taken further; I do not say that Dr. Knyvett Gordon would do so, and it is asserted that such blood changes connote pernicious anaemia and nothing else. — It is time that we ceased to have two meanings current

for this one term; it is time that the careful but brilliant work of Wm. Hunter should be allowed to dominate that of the specialist on blood pictures. I accept Dr. Knyvett as well qualified to speak from the pathologist's point of view, and should like to ask him the following questions:

1. Is the so-called "megaloblastic degeneration" a degeneration, and, whether it be so or not, can any particular factors which determine its development be specified?

2. Is it common to several disease processes or peculiar to one?

3. Can a diagnosis of "pernicious anaemia," carrying with it the usual significance of an inevitably fatal outcome, be made from a blood film alone?

—I am, etc.,

Sevenoaks, April 30th.

GORDON WARD.

### CANCER OF THE BREAST.

SIR,—There are many debatable points raised in Mr. Cecil Rowntree's lecture on cancer of the breast, published in the *BRITISH MEDICAL JOURNAL*, May 5th, 1923, and the section devoted to early diagnosis is rather disappointing. He rightly points out that the usual textbook description of a hard irregular mass infiltrating the breast, causing retraction of the nipple, and accompanied by enlargement of the axillary glands, need not concern us. But what sign does he offer the student on which to found his diagnosis of early cancer? A slight dimpling of the skin! Surely when a cancer is capable of "diagnosis" from its clinical signs it has long passed its early stage. A surgeon may guess correctly the nature of a small tumour of the breast, but is guessing scientific? It has been estimated that clinicians are unwilling to commit themselves to a diagnosis in over 20 per cent. of breast neoplasms. In these circumstances, what is a surgeon to do with these cases? Is he to take away a small piece of the neoplasm and await the pathologist's report, and submit the patient to a second operation? Is he to remove the breast? Is he to perform the major operation? Or is he to rely on the opinion of the pathologist from a frozen section at the time of the operation? The last method of procedure if reliable would certainly be the best for the patient and the surgeon. But Mr. Cecil Rowntree tells us that he has never been able to convince himself of the value of rapid frozen sections.

Dr. Ernest H. Shaw, who has practised the frozen section method for over twenty-three years, says<sup>1</sup> he has attended as pathologist to assist in 382 clinically doubtful tumours of the breast in the practice of a large number of surgeons, most of whom are well known. Further on in the same paper he writes of the pathologist who practises the frozen section method of diagnosis. "He (the pathologist) must be able to give a definite opinion as to whether the case he is dealing with is malignant or not. The surgeon expects a quick and definite report on which the fate of an important organ or even a limb often depends. I have made it a rule to have paraffin sections prepared of all my cases, and am pleased to be able to record that in every instance the pictures seen in the permanent sections have agreed exactly with those made immediately at the operation."

Again, Dr. W. C. MacCarty<sup>2</sup> writes, "It is unfair to perform a radical operation on the mammary gland in doubtful cases, but that it is fair with our present knowledge to remove a sector of the gland-bearing structure for immediate examination."

It is quite true that a pathologist, to be of immediate value to the surgeon, requires long training both in the macroscopic and microscopic characters of neoplasms. Pathologists make mistakes, but the cancer problem is to be faced scientifically; all methods available must be used at the earliest opportunity and in the early stage of cancer before it is capable of being clinically diagnosed. The immediate frozen section method in competent hands will be found a valuable agent in the fight against cancer. It certainly appeals to me as the reliable, sane, and scientific method of to-day and should certainly be more extensively used. It is the method capable of guiding the surgeon in the choice of operation and the

only method calculated to save the patient the distress and inconvenience of a second operation.—I am, etc.,

London, W., May 7th.

W. H. MCKINSTRY, M.D.

### RESTORATION OF THE HEART BEAT.

SIR,—With reference to the letters from Sir James Mackenzie (April 21st) and Dr. Harrington Sainsbury (May 5th) it may be of interest to refer to some recent observations I have made on the effect of adrenaline on the lower rhythmic centres of the human heart. A variable time after the hypodermic injection of 7 to 10 minims adrenaline chloride (1 in 1,000, Parke, Davis and Co.), it was found that pressure over either right or left vagus, by depressing the sinus rate, allowed a new slow rhythm to appear, which started in the auriculo-ventricular node or below this. The new rhythm was maintained for a variable number of cycles, according to the duration of the vagal stimulation, until the sino-auricular node escaped. This result has been attained in twelve observations made on seven subjects.

In the case of the apparently arrested heart, such a new rhythm once aroused would presumably continue and maintain a sufficient circulation to allow the normal pacemaker to recover and resume control of the heart's rhythm.—I am, etc.,

Hull, May 12th.

E. E. LASLETT.

### INSULIN AND DIABETES MELLITUS.

SIR,—I refrained from replying to Dr. Cammidge's letter in your issue of May 5th thinking that someone with more experience would explain that it is not possible at present to assert how far permanent benefit may accrue to diabetics from the administration of insulin.

I am in agreement with Dr. Cammidge in so far as to have made it a rule to explain to patients that when one embarks upon a course of insulin it may be necessary to continue it indefinitely. This incidentally adds great difficulty to its use in hospital. Personally, I do not treat patients in hospital with insulin unless I am satisfied that they will be able to obtain a supply after leaving. It is too cruel to let an individual learn that there is some substance which will allow him to live in comparative comfort, but because he has not money to buy it he must perish miserably. Some fund should be started to supply poor people with insulin: the State should not supply it. The administrators of the fund might stipulate that those whom they assist to pay for insulin must have no progeny: the State could not make this stipulation, and without it the diabetic population would increase, because the tendency to diabetes mellitus is undoubtedly hereditary. In the past the multiplication has been checked automatically, because a man suffering severely from diabetes is impotent, whilst a woman, even if she conceive, rarely bears a living child.

In spite of this, the data at our disposal at the moment do not allow us to conclude that cure does not occur. Rest is the greatest healer: poor nutrition is his greatest antagonist. In the past the islets of Langerhans could be rested only by fasting. Rest could only take charge of the patient accompanied by poor nutrition. We have reasons to believe—although we have no proof at the moment—that now we may be able to rest the islets whilst feeding the patient, so long as we give sufficient insulin to maintain a slight hypoglycaemia. All those who have had some little experience with insulin have met cases in which either the diet could be increased or the amount of insulin diminished after a few weeks' treatment designed to prevent any hyperglycaemia. In my opinion at the present time it is the duty of any practitioner who diagnoses diabetes mellitus, and has reason to believe that the onset of the disease is quite recent, to make arrangements for his patient to be treated with insulin without any delay. Many have designed and are carrying out experiments to estimate the improvement of the glycopyretic function of diabetics following a course of insulin.—I am, etc.,

London, W., May 11th.

O. LEXTON.

<sup>2</sup> *Collected Papers of the Mayo Clinic*, May, 1922.

## STERILIZATION OF THE UNFIT.

SIR,—In answer to the letter of Mr. Havelock Ellis, I may say that I quoted at length the Indiana law to show how much care was taken before the operation of sterilization was performed. He says that there never seems to have been any such law in Utah, but I have before me a summary of sterilization laws published in the *Journal of Criminal Law and Criminology*, a copy of which I was unable to obtain, but which is to be found in the *International Clinics* for 1920. Some may have been cancelled even since then. Therein I find:

"Utah has also passed a law similar to those cited. In most of these laws provision is made for severe penalties for those who perform the required operation for improper purpose."

My paper had for its object only the sterilization in our own country of the unfit, which, considering the enormous influence of heredity, would prevent the advent of mental defectives; and a State certificate of marriage, which, if effectively carried out, would tend to diminish the risk of infection by the *Spirochaeta pallida*, the gonococcus, and tubercle bacillus, for, should either be present, marriage could be postponed until health was established. There is no opposition to marriage in health. No legislation can prevent promiscuous intercourse, with its attendant risk.

It is evident that although Mr. Havelock Ellis approves of "a measure so excellent as eugenical sterilization, and so certain to be eventually recognized in general medical and surgical practice," he does not care for laws; but I hope that, at any rate in this country, should the operation ever be allowed, it will only be through legislation, and not "with the written consent of the relatives without reference to any law." The councillors of Utah would not be the only ones to be obliged to make provision for severe penalties when the operation was done for an improper purpose.—I am, etc.,

London, S.W., May 14th.

R. A. GIBBONS.

SIR,—Dr. R. A. Gibbons is reported (p. 760) as saying that "four children to a marriage were necessary to continue the State in view of the fact that some would die before maturity and some would not marry." I beg to point out that it was stated in *La question de la dépopulation*, by M. Leroy Beaulieu, that in 1901-1905 the average number of children per family in France was 2.5, that in 1906-1911 it was 2.32, and that in 1911 it was 2.18. Yet the population in France continued until the war to increase, by excess of births over deaths, at its usual rate of about one per thousand a year.—I am, etc.,

London, S.W., May 14th.

B. DUNLOP.

## INTRATHECAL INJECTIONS OF TRYPARSAMIDE.

SIR,—My attention has been arrested by a statement in the paper "The Treatment of Trypanosomiasis," by Marshall and Vassallo, in the *BRITISH MEDICAL JOURNAL* of February 10th, 1923, to the effect that I advocate the local or intrathecal injection of tryparsamide in the treatment of sleeping sickness. I desire to point out to your readers that I have never advocated this method of treatment and, indeed, with our present knowledge of tryparsamide, regard it as unnecessary.—I am, etc.,

New York City, May 7th.

LOUISE PEARCE.

An international exhibition of hygiene will be held at Strasbourg in commemoration of Pasteur from July to October, consisting of the following sections: (1) Bacteriology and parasitology, including tropical diseases, and diseases of animals and plants; (2) chemistry, and chemical industries, antiseptics, etc.; (3) general hygiene; hydrology, climatology, thalassotherapy, gymnastics; (4) public health questions in schools, the army, navy, colonies, out-patient departments, factories, etc.; (5) hospitals and insurance; (6) statistics and demography; (7) municipal hygiene, including building, ventilation, lighting, water supply, baths, parks, drainage, etc.; (8) food hygiene; (9) refrigeration industry; (10) agricultural hygiene.

## Obituary.

GEORGE HALIBURTON HUME, M.D. EDIN.,  
D.C.L. DUNELM., F.R.C.S. EDIN.,

Consulting Surgeon, Royal Infirmary, Newcastle-on-Tyne.

By the death, on May 8th, of Dr. G. H. Hume at the age of 77, Newcastle-upon-Tyne has lost a distinguished surgeon and a man held in very high esteem. For the last year or more he had been in indifferent health, and had led a semi-retired life. Dr. Hume had outlived most compeers whose acquaintance he made when he came to the city half a century ago.

He was born in Kelso, graduated at the University of Edinburgh in 1867, and continued his studies in Berlin and Vienna. His introduction to Newcastle occurred through a partnership with the late Mr. Septimus Rayne, then well known as the city police surgeon and as medical and surgical adviser to the North-Eastern Railway Company. At this period—the early seventies—Dr. Hume engaged in general practice and rapidly rose to be one of the most successful medical practitioners in the North of England. When, in 1875, the partnership was dissolved, Dr. Hume felt himself free, not only to occupy the post of surgeon to the infirmary, but gradually to devote himself more and more to surgery, for which he had a marked inclination. His surgical work was good. Speaking as a physician of a surgeon whom I have seen frequently operate, Dr. Hume, owing to his neat-handedness, seemed to excel particularly in small but delicate operations, in the performance of which patience and the taking of pains are so essential. A careful observer of disease and an attractive bedside teacher, he was a safe guide for students to follow.

For a few sessions Dr. Hume lectured on physiology in the School of Medicine in Neville Street. He possessed just that type of mind and love of the recondite facts of physiology and pathology which, with his gift of clear exposition, made him one of the most respected of lecturers. He was a man of great literary taste, of refinement and culture. Didactic and concise, his style and mode of expression made him an interesting and attractive speaker in medical societies and elsewhere.

When the British Medical Association met in Newcastle in 1893 he was invited to give the address in surgery. Choosing for his subject the evolution of surgical principles, he dwelt upon the rapid strides surgery had made under the Listerian treatment of wounds, and how the art of surgery had improved as its science had broadened. He wrote a history of the Royal Victoria Infirmary, and on the occasion of the opening of the institution by the late King Edward, His Majesty graciously accepted a copy of the book.

Dr. Hume's wife died several years ago, and his youngest son was killed in the recent war. He is survived by two sons—both well known in the medical profession—and by four daughters.

His body was laid to rest in St. Andrew's Cemetery on May 10th. The funeral was attended by a large gathering of colleagues and members of the medical profession, and by many old patients.

T. O.

We are indebted to Mr. H. BRUNTON ANGUS, Professor of Surgery in the University of Durham College of Medicine, for the following tribute:

By the death of George Haliburton Hume, M.D., D.C.L., F.R.C.S. EDIN., Newcastle-on-Tyne has lost a man of striking personality. Sprung from a Border yeoman stock, educated at Edinburgh University, he settled in Newcastle-on-Tyne, where he was fortunate in being appointed at an early age to the surgical staff of the Newcastle Infirmary. Never of robust physique, such was his devotion to work that he built up a large practice and also conscientiously fulfilled his duties to the hospital. As a surgeon he was characterized by the thoroughness and care which he devoted to his work. A very efficient operator, he shone by the soundness and excellence of his judgement. He had a keen critical mind which never lost sight of the best interests of his patients. The public were quick to discover

this trait and few men in Newcastle-on-Tyne have ever enjoyed such implicit confidence. As a teacher he was gifted with a lucid style and fluent speech; drawing from his rich experience he held the close attention of his students. Outside of professional matters his balanced judgement made him a trusted adviser and friend. He was a refined, scholarly man, a great student of history and a brilliant conversationalist. His *History of Newcastle Infirmary* is a worthy monument to his literary ability and love of historical research. Of a retiring disposition, he never sought public notoriety, but to those who enjoyed the privilege of his friendship he was a charming companion.

A strong family man, his later years were darkened by the death of his wife and the loss of his youngest son, who was killed in the great war. These were blows which he felt deeply, but he bore them with the same unfaltering courage that he displayed when his own health failed. His last two years proved a severe trial; conscious of his steady decline, with mind clear even to the last week of his life, he neither complained nor repined but faced the inevitable with sublime heroism.

#### ARTHUR LOOSS, Ph.D.,

Formerly Professor of Parasitology, Cairo.

We learn with regret that the distinguished helminthologist, Dr. Arthur Looss, died after a long illness on May 4th, at Giessen. Dr. Looss was born on March 16th, 1861, at Chemnitz, where his father was a works director. He received his early education in his native town and at Lodz in Poland. In 1880 he matriculated at the University of Leipzig as a student of natural science, and attended the lectures of Professors Credner, Haeckel, and Hoffmann, and worked in the laboratories of Professors Leuckart, Schenk, Wiedemann, and Dr. Fraiine. In 1885 he received the doctorate of philosophy for a thesis on the Trematodes.

For some years he lectured in Leipzig, and later on was sent by Leuckart to Egypt to investigate the transmission of bilharzia. Failing to implicate the molluscan fauna in the spread of the disease he arrived at the conclusion that infection took place directly from man to man through the skin. During the inquiry Looss studied also the development of *Ankylostoma duodenale*, and accidentally infected himself. This led to his remarkable series of observations which demonstrated for the first time that infection takes place through the skin, and that the larvae there are carried to the heart and lungs, finally reaching the alimentary canal from the trachea. The two volumes on the anatomy and life history of the hookworm published by Looss in the records of the Government School of Medicine show him at his best as a most detailed and accurate observer, as well as a highly skilled artist. His other contributions to medical helminthology comprise briefer but equally masterly descriptions and illustrations of *Heterophyes heterophyes*, *Trichostrongylus subtilis*, *Filaria loa*, and *Schistosoma japonicum*. His monograph on the *Sclerostomidae* of horses has proved to be one of the most important helminthological contributions to veterinary science. Looss's predilection lay, however, with the trematodes, and the series of monographs on the classification of the distomes, beginning in 1899, completely revolutionized the basis of classification of this group. For many years Looss was professor of parasitology and biology at the School of Medicine in Cairo, where he lectured with remarkable lucidity and earnestness to the Egyptian students in their first year of medical studies. It was not until some time after the outbreak of the world war that his professorial duties were suspended. With the entry of Turkey as an ally of Germany he was permitted to retire from his chair and return to Germany. Separation from his library and collections, and the crushing sorrows which fell upon his friends and country overcast the last years of his life, which were quietly spent in teaching at the University of Giessen. In spite of a peculiarly dogmatic manner and an acrid controversial style which brought him into conflict in turn with Railliet, Stiles, Manson, Leiper, and Sambon, Looss was in private life a man of simple and lovable character, and one who had many friends of many nationalities, for he was an accomplished linguist.

Helminthology and philately were his hobbies. Twice he visited England, on the first occasion to receive the Mary Kingsley medal of the Liverpool School of Tropical Medicine. His second visit took him to Cambridge, where an extended tour of the colleges was arranged for him. After viewing three, he pathetically appealed to his host with the remark, "Ach, they are all the same, now show me some worms." This single-minded absorption in a field of study which at one time many considered to be exhausted has won for Looss an imperishable name, and placed upon humanity a debt which posterity must eventually acknowledge.

WE regret to record the premature death, on April 21st, after an operation, of Dr. S. JERVOIS AARONS, of 17, Harley Street. Dr. Aarons was Australian by birth, and was educated at the Universities of Sydney and Edinburgh; he was a popular president of the Union at Edinburgh. He graduated M.B., C.M. Edin. in 1895, and M.D. in 1897, and became M.R.C.P. Lond. in 1904. After having been house-surgeon in the gynaecological wards of the Edinburgh Royal Infirmary, and tutor in midwifery and gynaecology at the Edinburgh Extra-Mural School, he settled in London, and held the appointments of pathologist and registrar at the Hospital for Women, Soho Square. At the time of his death he was gynaecologist to St. Anthony's Hospital, Cheam. Dr. Aarons was a man of brilliant personality and kindly nature; he was perhaps best known for his work on sterility, on which subject he wrote in the *Index of Treatment*. He was the author of a small book on *Gynaecological Therapeutics*, a volume of modest aims but of real practical value, and he also contributed many articles to the literature of gynaecology.

### Universities and Colleges.

#### VICTORIA UNIVERSITY, MANCHESTER.

THE Earl of Crawford and Balcarres has been nominated Chancellor of the University, in succession to Viscount Morley, who has resigned on the ground of advancing years. Lord Crawford is the head of the house of Lindsay, has been a Cabinet Minister, and is trustee of the National Gallery and the National Portrait Gallery.

Professor J. S. B. Stopford has been appointed Dean of the Medical School as from September next, in succession to Professor R. B. Wild.

A ceremony for the conferment of medical degrees will be held on Saturday, July 14th.

#### UNIVERSITY OF SHEFFIELD.

MR. ERNEST FINCH, M.D., M.S. Lond., F.R.C.S. Eng., has been appointed to a lectureship in surgery.

#### ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN extraordinary comitia of the Royal College of Physicians of London was held on Thursday, May 10th, at 5 p.m., the President, Sir Humphry Rolleston, being in the chair.

The following gentlemen, elected to the Fellowship at the last comitia, were admitted as Fellows:

Richard Hingston Fox, M.D. Brussels, John Porter Parkinson, M.D. Lond., Donald George Hall, M.D. Camb., Wilfrid Stephen Fox, M.D. Camb., Frank Edward Tylecote, M.D. Manch., John Owen, M.D. Lond., Leonard Gregory Parsons, M.D. Lond., John Parkinson, M.D. Lond., Alfred Hope Gosse, M.D. Camb., Philip Henry Munson-Bahr, D.S.O., M.D. Camb., Sir Hugh Kerr Anderson, M.D. Camb., Byrom Bramwell, M.D. Edin.

A communication was received from Dr. J. J. Perkins, resigning his examinership in medicine as from July next.

A report was received from Dr. Drewitt, who represented the College at the bicentenary of the death of Sir Christopher Wren. The thanks of the College were conveyed to Dr. Drewitt by the President.

Dr. Edwin Goodall was appointed a representative of the College at the University of Wales, vice Dr. H. W. G. Mackenzie, resigned. A vote of thanks was accorded to Dr. Mackenzie for his services.

An address to his Royal Highness the Prince of Wales, President of St. Bartholomew's Hospital, on the occasion of the 800th anniversary of its foundation, was sealed.

#### ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary Council was held on May 10th, when Sir Anthony Bowlby, President, was in the chair. Diplomas of Membership were issued to 150 candidates recently found qualified. Twenty candidates were found qualified for the Diploma in Public Health, in conjunction with the Royal College of Physicians. (The names were published in the report of the comitia of the Royal College of

Physicians, May 5th, p. 792.) Ten candidates were found qualified, in conjunction with the Royal College of Physicians, for the Diploma in Tropical Medicine and Hygiene. (The names were published in the report of the committee of the Royal College of Physicians, May 5th, p. 792.)

Mr. Hugh Lett was elected a Member of the Court of Examiners.

A letter was read from the Clerk of the Barbers' Company stating that, subject to the consent of the Royal College of Surgeons, the Thomas Vicary lecture should be continued for a further period of five years.

## Medical News.

THE subject selected for Sir John Bland-Sutton's Emeritus lecture at the Middlesex Hospital Medical School, on June 5th, is the choroid plexus and ventricles of the brain as a secreting organ.

THE Cavendish lecture of the West London Medico-Chirurgical Society will be delivered by Dr. Henry Head on "Speech and cerebral localization" on June 22nd, at 8.15 p.m., at Kensington Town Hall. The annual dinner of the society will be held at the Monaco Restaurant on June 19th at 7.45 p.m., with Dr. A. G. Wells, President, in the chair. Further particulars and tickets may be obtained from Dr. Guy Chambers, 101, Goldhawk Road, W.12.

THE twelfth biennial Huxley lecture, on recent advances in science and their bearing on medicine and surgery, will be given at the Charing Cross Hospital Medical School by Professor Sir Arthur Keith, F.R.S., on Wednesday, June 27th, at 3 p.m. The chair will be taken by Dr. William Hunter, C.B., and admission will be free without ticket.

A GENERAL meeting of the Medical Society for the Study of Venereal Diseases will be held at 11, Chandos Street, W.1, on Friday, May 25th, at 8.30 p.m. Sir Thomas Horder will give an introductory address on metastatic gonorrhoea, and Sir William Willcox will open a discussion on gonococcal arthritis.

SIR ROBERT ARMSTRONG-JONES, M.D., will deliver the Gresham lectures on physics at the Gresham College, E.C., on May 22nd, 23rd, 24th, and 25th, at 6 p.m. each evening. The subject will be medical hydrology and hydropathy, with special regard to the climate of health resorts in England and Wales. The lectures are free to the public.

WE are asked to state, with reference to the special course of medical hydrology arranged by the University of London Extension Board (see JOURNAL, April 28th, p. 735), that medical students are invited, without fee, to attend the whole course, and medical practitioners to attend the two opening lectures, on May 29th, at the University of London, South Kensington.

A MEETING of the Medical Officers of Schools Association will be held at 11, Chandos Street, W.1, on Tuesday, May 29th, at 5 p.m., when Dr. Alice E. Sanderson Clow will read a paper on the effect of physical exercise on menstruation.

THE University of Glasgow proposes to confer its honorary degree of LL.D. upon Dr. Graham Lusk, professor of physiology in Cornell University, and not as previously announced.

THE Llandrindod Wells Open Medical Golf Challenge Cup was played off on May 2nd, 3rd, and 4th. In the semi-finals Dr. J. C. Hunot (8) beat Dr. D. Evans (10) 3 and 1; Dr. D. Saunders Jones (9) beat Dr. A. Davies (6) 5 and 4. In the finals Dr. D. Saunders Jones beat Dr. J. C. Hunot (the winner last year) 6 and 5. Lady Mayo Robson presented the cup and replica. The competitors were entertained to luncheon at the Golf House by the local committee. Toasts were proposed and responded to by Dr. Evans (Pennard), Dr. Baird (St. Leonards), and others, who all spoke highly of Llandrindod Wells and its facilities for various treatments.

THE examination of the Central Midwives Board for Scotland, held simultaneously in Edinburgh, Glasgow, Dundee, and Aberdeen, has just concluded. Out of 95 candidates who appeared for the examination 87 passed. Of the successful candidates 27 were trained at the Royal Maternity Hospital, Edinburgh; 20 at the Royal Maternity Hospital, Glasgow; 3 at the Maternity Hospital, Aberdeen; 9 at the Maternity Hospital, Dundee; 7 at the Queen Victoria Jubilee Institute, Edinburgh; 4 at the Cottage Nurses Training Home, Govan, Glasgow; and the remainder at various recognized institutions.

THE annual summer meeting of the Medical Golfing Society will be held at Addington (by kind permission of the Addington Golf Club) on Thursday, June 14th. Entries, with lowest handicap, must be sent to the honorary secretary, Dr. Rolf Creasy, jun., 25, Devonshire Place, W., on or before Monday, June 11th. The entry must be accompanied by the annual subscription of 10s., if due. All medical men on the *Medical Register* are eligible for membership of this society.

THE Fellowship of Medicine have arranged a further series of post-graduate lectures, open to members of the profession, to be given by kind permission of the Royal Society of Medicine, at 1, Wimpole Street, W.1. The opening lecture on Wednesday, May 30th, at 5.30, will be given by Mr. Ernest Clarke on tips in ophthalmology for the general practitioner, and others will follow by Mr. R. A. Hendry, Mr. James Berry, Sir Sydney Russell-Wells, Sir Henry Gauvain, Mr. Harold Chapple, and Mr. H. S. Souttar. Copies of the complete programme will be forwarded on application to the Secretary to the Fellowship of Medicine, 1, Wimpole Street, W.1. A course of eight practical lecture-demonstrations on gastro-intestinal diseases of children will be given by Professor Sir William Bayliss, Dr. Bernard Myers, and Mr. E. T. O. Milligan at the Children's Clinic, Western General Dispensary, Cosway Street, N.W.1, from Monday, June 11th, to Thursday, July 5th. The fee for the course is £1 ls., or lectures can be taken singly, if desired. Copies of the syllabus can be obtained from the Secretary to the Fellowship of Medicine, 1, Wimpole Street, W.1. The lectures will be delivered at 5 p.m. on each day.

THE societies engaged in the educational health and food campaign organized by the Bread and Food Reform League, in association with other scientific and sociological societies, have asked the Minister of Health to receive a deputation which desires to direct attention to the importance of introducing legislation to notify and limit the presence of preservatives in food, and to urge the necessity of publishing educational leaflets giving information about healthy and economical foods.

AT the solemnity in the hospital square on Tuesday, June 5th, during the celebration of the 800th anniversary of St. Bartholomew's Hospital, the musical arrangements will be under the supervision of Lieut.-Colonel J. Mackenzie Rogan, C.V.O., who has composed fanfares for trumpets and drums specially for the occasion; these will be played by the Coldstream Guards band. The band of the Welsh Guards will play a selection of music.

A COURSE of eight lectures on surgery will be given by members of the staff in the London Hospital Medical College, commencing on May 25th at 4.15 p.m., when Mr. Russell Howard will lecture on the testicle. The course is intended for senior students and post-graduates.

THE eighth French Congress of Legal Medicine will be held in Paris from May 24th to 26th under the presidency of Dr. Pierre Parisot. M. Courtois-Suffit and Giroux will introduce a discussion on the international regulation of the sale of cocaine. There will be discussions also on industrial diseases, on the identification of blood, and on injuries to the vertebral column. A special meeting of the French Society of Legal Medicine will be held on May 26th, and a discussion will take place on the declaration of deaths in France.

A CRICKET match will be played at Brentwood on June 20th, at 2.30 p.m., between the Essex Doctors and the Southend Doctors. Any Essex medical man who would like to take part in the match should communicate with Dr. Horace E. Haynes, Littleton Hall, Brentwood, Essex.

DR. T. S. HIGGINS, M.O.H. St. Pancras, and Dr. J. SPENCER LOW, a medical officer of health of the Ministry of Health, have been elected Fellows of the Royal Sanitary Institute.

THE next examination of the Dental Board, which will be held in Edinburgh on July 6th and 7th, in Manchester on July 18th and 19th, and in London on July 26th and 27th, affords the last opportunity for those persons entered under Section 3 (2) of the Dentists Act, 1921, to present themselves, unless they be entered as war service candidates. Notices have been addressed to persons whose names are entered on the list. Any eligible person who has not received such a notice should communicate with the Secretary for Examinations, Dental Board, 44, Hallam Street, London, W.1.

THE annual medical dinner for Southampton and district, the fourth of the series, was held on the night of Wednesday, May 9th, at the South-Western Hotel, Southampton, and was well attended by the doctors residing in the town, and even from so far afield as Botley and Romsey. After the toast of "The King," the chairman, Dr. Farquharson, made a reference to the late Dr. Purvis, whose memory was honoured, standing and in silence, by the company. A musical programme was supplied by Mr. Leonard Munn, who kept the audience interested and amused for over an hour with a varied programme of songs, stories, and piano. Several items were also given by Dr. Hamilton, whose splendid voice was very much appreciated, and a very entertaining evening was brought to a close at 10.45 p.m. by the singing of "God Save the King."

MESSRS. WILLIAM HEINEMANN (Medical Books) LTD., have in the press *Aromatics and the Soul*, by Dr. Dan McKenzie, M.D., and *The Hygiene of Marriage*, by Mrs. Hutton, M.D., with a preface by Professor A. L. McClellroy.

## Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

The postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology*, Westrand, London; telephone, 2630, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Mediscera*, Westrand, London; telephone, 2630, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Dacillus*, Dublin; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate*, Edinburgh; telephone, 4361, Central).

### QUERIES AND ANSWERS.

#### INCOME TAX.

"R. W. S. C." gave up his practice at the end of March or beginning of April, 1916, subsequently earned a few fees as locum-tenent, and joined the R.A.M.C. on September 7th, 1916. He has recently received an application for payment of £21, income tax assessed on his earnings as for the year 1916-17.

\* \* Provided the assessment was made by April 5th, 1920, the tax is legally recoverable. But it may be assumed that the authorities would be willing to make any adjustment necessary to bring the amount down to a proper figure. "R. W. S. C." should therefore ask for full particulars as to the precise amount of income assessed and supply a statement of the fees earned by him from April 5th, 1916, to September 7th, 1916. He might also take steps to ascertain what was his assessable military pay and what allowances were made to him when that was assessed to tax, as there may be some balance of allowances to be set against the assessment on the civil earnings.

"SENEX" is in receipt of retired pay from the Government and income from various taxed and untaxed sources. He has been medically advised to reside on the Continent, and inquires what abatement he would receive if he left the United Kingdom and established his ordinary residence abroad.

\* \* He would be entitled to exemption from tax on income not arising from this country and on interest from most of the war issues—for example, 5 per cent. War Loan. On the other hand, the allowances which he receives at present would be restricted to the proportion which his liable income would then bear to his total income.

"A. B." has an income of £500 a year, all of which is taxed at its source. How will he benefit by the £225 allowed him?

\* \* Taking the year 1922-23 as an example, he is entitled to repayment of

£225 at 5s.	...	...	...	...	...	£56 5 0
£225 at 2s. 6d.	...	...	...	...	...	£28 2 6
						£84 7 6

He can claim repayment of this amount through the inspector of taxes for the town in which he resides, on the usual official form of claim which the inspector will supply on request.

### LETTERS, NOTES, ETC.

#### TREATMENT OF DIABETES.

DR. C. MUTHU (Mendip Hills Sanatorium) writes: I am glad Dr. Cammidge, in your issue of May 5th (p. 787), has raised a note of warning with regard to "optimistic forecasts" of insulin in the treatment of diabetes. May I relate my experience during my recent visit to India? I had the privilege of seeing and examining 6 cases of diabetes in different parts of India which were cured by simple fasting. One of these cases was a medical man practising in Nepal, who fasted the first week, taking nothing but butter milk, and during the second, third, and fourth weeks

fasted two days a week and reduced his diet on the other days to a fourth of what he took before. At the end of the month he completely recovered and was none the worse for his fasting experience. I am sure that diabetes, at least in India, is due to an over-indulgence of rich foods and to an excessive meat diet with little or no exercise whereby the gastric organs—the liver and pancreas—get overworked and fatigued; and the abstinence from food gives them time to recover their exhaustion and renew their normal metabolism. I have seen other cases besides diabetes do well by fasting treatment. I myself got rid of commencing dysentery by fasting two days and taking nothing but orange juice. I saw a case of paralysis agitans in a fat purdah lady in whom both her weight and the tremors of head and hands were considerably reduced on a diet of nothing but oranges. Another case was a lad of 14 with a voracious appetite who got rid of his asthmatic attacks when his diet was considerably reduced and his bowels attended to. There is no doubt that civilized man, by over-indulging in eating and drinking and thus overworking his digestive organs, invites diseased conditions, and that in partial or strict fasting and regulation of diet the medical profession has a simple but efficient remedy in the treatment of diabetes and many another disease.

#### THE INFLUENCE OF INTESTINAL BACTERIA UPON THE THYROID GLAND.

"K." writes with reference to Dr. Harries's paper on disease of the thyroid gland (BRITISH MEDICAL JOURNAL, March 31st, p. 553): I had a case regarded as early exophthalmic goitre by a consultant and another doctor. Laboratory reports on specimens of urine were: first, "indican—a trace"; secondly, "indican—none." After four weeks of the usual treatment, without improvement, the patient was put on thyroid, 1 grain daily, tincture of iodine, 5 minims thrice daily, and decided improvement ensued. The question arises as to what other conditions are associated with absence of indican in the urine, interfering with its utility for diagnosis and prognosis in exophthalmic goitre.

#### THE DETERMINATION OF LABOUR.

DR. HEXWOOD SMITH (Chichester) writes with reference to the discussion on the legal period of gestation before the Medico-Legal Society on April 17th (BRITISH MEDICAL JOURNAL, April 21st, p. 691): Is not the menstrual cycle the determining factor in the calculation of the commencement of labour? I used to calculate for my patients that labour was due at the beginning of the tenth "period," reckoned from the first day of the last menstruation, and it usually proved correct within a week. For instance, if the last "period" began on January 1st, labour was due on September 10th, and would probably take place before the 17th. May I draw attention to a mistake that is not infrequently made by authors of communications in using the word "pubis" instead of "pubes"? "Pubis" is the genitive case.

#### CUPPING.

DR. J. R. KEITH (Driffield) writes: In the interesting communications which have appeared recently in the JOURNAL with regard to cupping I see no reference to a very effective and easy method of carrying it out—namely, the vacuum glasses which have been devised by A. Bier and R. Klapp for the treatment of various inflammatory conditions. These glasses, which were originally manufactured by Eschbaum of Bonn, may now be obtained from makers of surgical instruments in this country. A convenient glass to use is one 2½ inches in diameter, which, held in position by an assistant, is exhausted by the operator by means of a suction pump which is connected with the glass by a short piece of rubber tubing.

#### CORRECTION.

DR. D. MONTAGUE B. SNELL calls attention to an error in the qualifications printed after his name in the JOURNAL of May 12th (p. 809 and Contents page). For M.R.C.P. read L.R.C.P.

#### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 30, 31, 34, 35, and 36 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 32 and 33. A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 207.

#### SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	...	...	0 9 0
Each additional line	...	...	0 1 6
Whole single column (three columns to page)	...	...	7 10 0
Half single column	...	...	3 15 0
Half page	...	...	10 0 0
Whole page	...	...	20 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, W.C.2, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restant* letters addressed either in initials or numbers.

## A British Medical Association Lecture

ON

## THE PATHOGENESIS OF RICKETS.\*

BY

ERIC PRITCHARD, M.A., M.D. OXON.,

M.R.C.P. LOND.,

MEDICAL DIRECTOR, INFANTS' HOSPITAL, WESTMINSTER; CONSULTING PHYSICIAN TO THE QUEEN'S HOSPITAL FOR CHILDREN.

EVIDENCE derived from experimental and clinical work on the subject of rickets has accumulated so greatly during recent years that we are now in a position to review in reasonable perspective many of the rival theories which from time to time have been advanced, to explain both its etiology and its pathogenesis.

There is scarcely any element in the food which, at one time or another, from the days of Glisson (1650) downwards, has not been incriminated, as the guilty factor in the causation—sometimes on the grounds of excess, sometimes on the grounds of default. Further, apart from food causes, there are few factors in the general hygienic environment—whether connected with bad housing, with confinement, with infection, with want of exercise, or with want of light—which have not been regarded by one or other authority as having an important bearing on the etiology. During the recent renaissance of interest in these sides of the subject there has been a distinct tendency for investigators to range themselves definitely either on the side of the dietetic theory or on that of the environmental explanation; but the deeper each party probes into the problem the greater are the concessions which it is compelled to make to the claims of the other, so that what appeared quite a short time ago to be a sharp line of demarcation between the two standpoints has now become an ill-defined neutral zone.

I do not think that at the present moment any impartial person who has at all followed the recent controversy would question the general truth of any of the hypotheses which have been formulated by either of the rival parties. Nobody, I believe, has any doubt that Mellanby is correct in his view that the fat-soluble "A" factor plays an important part both in the cure and prevention of the disease. Neither do I think he would quarrel with the claim made by Findlay and others that housing conditions, confinement, and want of exercise have a share in the etiology; nor with Buchholz (1904), Chick, Hume, and Mackay (1922), in their belief that ultra-violet rays have both a prophylactic and a curative influence on the rachitic changes in bone; nor with Noël Paton in his view that infection also plays a part; nor, for the matter of that, would he dispute the possibility of carbohydrate excess (Rabagliati and Hutchison), or protein deficiency (Henry), or defects of balance with respect to calcium or phosphorus, or any other of the constituents of the food being concerned in the causation of the rickety syndrome. I think it would not be overstating the case to say that at the present time most reasonable people are agreed that there is not any single cause of the disease, but there are many possible contributory factors which may exist in a great variety of combinations.

If, however, there is agreement as to the multiplicity of these remote or contributory causes, there is absolutely no unanimity of opinion as to the *causa vera* or the exact pathological process which can explain how it is that the same end-result can be reached by so many routes. Some authorities have regarded some disturbance of calcium metabolism or some faulty relationship between the phosphorus and calcium balance as the common point at which all these convergent paths meet, and many painstaking investigations have been carried out by Stheeman, Hess, McCollum, and others to estimate the exact composition of the blood in respect of these elements under normal and rickety conditions. Although there appears to be a distinct tendency for both the calcium and phosphorus content to show a noticeable diminution in cases of active rickets, and especially in the extreme phases of tetany
